Almagro, a town in Spain in the province of Ciudad-Real, 12 m. from the city of Ciudad-Real, in the midst of an elevated sterile plain. Its streets are wide and well paved and there is a large open public square. Lace is made here to a considerable extent, as well as soap, brandy, and coarse pottery. It is best known, however, as the centre of Valdepeñas district. Pop. (1900) 8,015.

Almalee, a town of Asiatic Turkey, on the river Myra, 25 m. from its mouth, and 50 m. W.S.W. of Adalia. It is beautifully situated in a kind of natural amphitheatre enclosed by lofty mountains. It has thriving manufactures and a considerable trade. Pop. 12,000.

Alma Mater, a term familiarly applied by those who have attended a university to the particular university they have attended. The adjective *almus* in Latin means cherishing, fostering, dear.

Almanac, a table or calendar, in which are set down the revolutions of the seasons, the rising and setting of the sun, the phases of the moon, the most remarkable conjunctions, positions, and phenomena of the heavenly bodies, for every month and day of the year; also the several fasts and feasts to be observed in the Church and State, etc. The history of the almanac, and even the etymology of the word, are involved in considerable obscurity. It is generally derived from the Arabic article *al*, and the verb *manach*, to count. The modern almanac answers to the *fasti* of the ancient Romans. Almanacs became generally used in Europe within a short time after the invention of printing; and they were very early remarkable, as some are now in England, for the mixture of truth and falsehood which they contained. In 1579 their effects in France were found so mischievous, from the pretended prophecies which they published, that an edict was promulgated by Henry III. forbidding any predictions to be inserted in them relating to civil affairs, whether those of the State or of private persons. No such law was ever enacted in England. It is singular that the earliest English almanacs were printed in Holland on small folio sheets; and these have occasionally been preserved from having been pasted within the covers of old books. In the reign of James I. letters patent were granted to the two universities and the Stationers' Company for an exclusive right of printing almanacs. These, in 1775, were declared to be illegal. During the civil wars of Charles I., and thence onward, English almanacs were conspicuous for the unblushing boldness of their astrological predictions and their determined perpetuation of popular errors. The Stationers' Company, who had managed to retain a monopoly notwithstanding the invalidity of the letters patent in their favor, were guided merely by commercial principles in supplying the market, and accordingly adapted their almanacs to the taste of the public, which, on one occasion, when the trial was actually made, refused to purchase them without the predictions. Gradually, however, a better taste began to prevail, and in 1828 the Society for the Diffusion of Useful Knowledge had the merit of

taking the lead in the production of an unexceptionable almanac in Great Britain. The example thus set has been almost universally adopted. Almanacs, from their periodical character and the frequency with which they are referred to, are now more and more used as vehicles for conveying statistical information. Regiomontanus was the first person in Europe who prepared almanacs in their present form, without the predictions, which were in all probability introduced into Europe from the Persians. Once they were almost entirely filled with subjects of a religious character. At another time they overflowed with astrological calculations and predictions. In the time of Napoleon an almanac was published in France, in which, to every day, an achievement of the emperor, or something else relating to him, was added. Almanacs, in the petty principalities of Germany, exhibit the endless genealogical tables of the princes. Some almanacs in modern Greek, printed at Venice, where formerly all books in this language were published, are quite full of astrological superstition and matters relating to the Greek Church. A modern Persian almanac contains a list of fortunate days for certain purposes; as, for example, to buy, to sell, to take medicine, to marry, etc.; and predictions of events, as earthquakes, storms, political affairs, etc. One of the most curious almanacs is an Italian one, exhibiting Italian vivacity in a striking manner. To the entry 30 July is added, *Sudano ancora le ossa!* (Even the bones sweat); to 11 August, *Oh! che noia!* (Oh! how distressing!); to 12 July, *Cascano le braccia* (The arms fall); to 2 January, *Stivali e ombrello!* (Leggings and umbrellas!) In Germany, *almanach* is the name given to annuals like those which used to appear in England and the United States under the names of 'Souvenir,' 'Forget-me-not,' etc. In France a work once appeared annually, entitled 'Almanach des Gourmands,' which was conducted with much spirit and is in high repute among epicures. Some of the almanacs that are regularly published every year are extremely useful, and are indeed almost indispensable to men engaged in official, mercantile, literary, or professional business. Such in Great Britain are 'Oliver & Boyd's Edinburgh Almanac,' 'Thom's Official Directory,' and the 'British Almanac,' with its 'Companion.' 'Whitaker's Almanac' is also known as a very comprehensive and valuable compendium. The 'Almanach de Gotha,' which has appeared at Gotha since 1764, contains in small bulk a wonderful quantity of information regarding the reigning families and governments, the finances, commerce, population, etc., of the different States throughout the world. It is published both in a French and in a German edition. 'The Nautical Almanac' is an important work published annually by the British government, two or three years in advance, in which is contained much useful astronomical matter, more especially the distances of the moon from the sun, and from certain fixed stars, for every three hours of mean time, adapted to the meridian of the Royal Observatory, Greenwich. By comparing these with the distances carefully observed at sea the mariner may with comparative ease infer his longitude with sufficient accuracy, in case he has no chronometer for keeping Greenwich time. This almanac was commenced in 1767 by Dr. Maskelyne, astronomer royal. The French 'Connaissance des Temps' is published with the same views as the English 'Nautical Almanac' and nearly on the same plan. It commenced in 1679. Of a similar character is the 'Astronomisches Jahrbuch,' published at Berlin. The 'American Ephemeris and Nautical Almanac' is issued annually since 1855 by the United States government.

The first American almanac was that of William Pierce of Cambridge, published in 1639. The most famous of American almanacs was 'Poor Richard's' published in Philadelphia by Benjamin Franklin under the pseudonym of "Richard Saunders." This almanac was probably imitated from that of Thomas, of Dedham, Mass., which was kept for a good many years and contains many pleasant and witty verses, jests, and sayings. The information printed in these almanacs seems to have been the only means of carrying news to the more distant parts of the country. 'The American Almanac' appeared between 1830–61, and a second publication under the same name was edited for several years by Ainsworth R. Spofford. Several of the largest newspapers in the United States now issue almanacs which are marvels of condensed information. See CALENDAR.

Al'mandite, or **Al'mandine,** a variety of the garnet (q.v.).

Alman'sa, a town of southeastern Spain (Murcia), near which was fought (25 April 1707) a decisive battle in the War of the Spanish Succession, when the French, under the Duke of Berwick, defeated the Anglo-Spanish army under the Earl of Galway. Pop. 8,000.

Alman'zur, or **Almansur,** a caliph of the Abasside dynasty, reigning 754–775. He was cruel and treacherous and a persecutor of the Christians, but a patron of learning.

Alma-Tadema, Laurenz, Dutch painter: b. West Friesland, Holland, 8 Jan. 1836. He was educated at the Antwerp Academy of Fine Arts under the artist Leys and obtained a medal at the Paris Salon of 1864 and another at the Paris Exposition of 1867. He went to England to live in 1870, exhibiting at the Royal Academy that same year 'Un Amateur Romain,' and 'Un Jonglier,' which attracted immediate attention. He became a member of the Royal Academy in 1879, and in 1899 was knighted. His especial field is the portrayal of Greek and Roman life, and all his work is marked by the most careful attention to archæological details. He is scholarly in execution, his coloring accurate, and his artistic feeling rarely at fault, but while his canvasses attract the eye and delight the intellect they seldom touch the heart. Among his more noted pictures are 'The Vintage Festival'; 'The Four Seasons'; 'Antony and Cleopatra'; 'The Women of Amphissa'; 'An Audience at Agrippa's'; and 'A Reading from Homer.' See Zimmern's 'L. Alma-Tadema: His Life and Work' (1886).

Alma-Tadema, (Miss) Laurence, English novelist: b. in England. She is the second daughter of the noted artist, L. Alma-Tadema (q.v.) and has published 'Love's Martyr'; 'The Wings of Icarus'; 'The Crucifix,' a collection of tales; 'Realms of Unknown Kings,' a book of verse; 'The Fate Spinner' (1900); 'The Unseen Helmsman' (1901).

Almond, the tree and nut of *Amygdalus communis* of the natural order *Rosaceæ,* supposedly a native of the Mediterranean region and of southwestern Asia, but so long in cultivation that its origin is a matter of conjecture. In habit of growth the tree, which reaches a height of 20 or 30 feet, is like the peach, with which some botanists surmise that it was formerly identical, but from which, by selection, it has become differentiated, the hard, inedible pulp of its fruit (a drupe), which splits at maturity and and exposes the pit or "almond" of commerce, being replaced by the edible fleshy part prized in the peach. Varieties of almonds are classed as bitter or sweet. The former, little grown outside the Mediterranean region, furnish prussic acid and oil of bitter almonds used in perfumery and culinary preparations; the latter, grown extensively in California and southern Europe and in similar climates, furnish one of the most agreeable of nut fruits. The sweet almonds are divided into hard- and soft-shelled varieties, the former little grown, the latter extensively. Some specially thin-shelled sorts are known as paper-shells. The kernels, particularly of sweet almonds, are rich in a mild fixed oil which is expressed for medicinal and other purposes, but the nuts are chiefly used for dessert, either directly or in some prepared form, such as confectionery.

The almond succeeds best upon light, thoroughly drained soil so situated that early frosts, which destroy the fertility of the blossoms, need not be feared. The trees, which are generally propagated by budding the desired varieties upon bitter almond seedlings, are set about 25 feet apart, different varieties that blossom simultaneously being planted in each other's proximity to ensure cross-pollenation, self-sterility being characteristic of many varieties. If trees are properly trained during their first three or four years they demand little severe pruning afterward. Cultivation does not differ materially from that of other tree-fruits. In California the nuts are harvested from August to October, dried for several days, and if discolored, as is often the case where the air is very humid, they are lightly sprayed with water and then treated with sulphur fumes to bleach the shells somewhat. Nuts that are too badly discolored to respond to this treatment are cracked by machinery and the kernels sold largely to confectioners. Because frost and self-sterility have been often overlooked, almond-growing in California has been remarkable for failures; many orchards have been cut down for firewood. But when and where conditions are favorable the crop is a profitable one. In 1897 218 carloads were shipped from California; in 1898 only 25. Planting in that State is practically at a standstill. Attention has been drawn to parts of Arizona and New Mexico as probably adapted to the almond, and some orchards have been planted. About $1,000,000 worth of almonds are imported annually. The almond is attacked by a vegetable fungus which appears first as a yellow rust on the leaves. This often leaves the tree bare of foliage as early as 15 July. Spraying is the only remedy. See FUNGICIDES.

As an ornamental tree the almond, like the peach, is often planted even in localities unfavorable to fruit-production. But its relative, the dwarf almond (*Amygdalus nana*), a native of southern Russia, is hardy and is recommended as an ornamental shrub by nurserymen for northern climates.

Aloë, a genus of succulent-leaved plants of the natural order *Liliaceæ,* natives of warm countries. The numerous species range in height from a few inches to 25 feet or more. Some are valued for their fibre, which is used for cord-, net-, and fabric-making: others for the medicinal qualities ascribed to them. Chief among the latter are several arborescent species, *Aloë succotrina, A. spicata, A. purpurascens,* and *A. arborescens,* from which Cape aloes is mainly derived, and *Aloë vera,* an East and West Indian species found also on certain islands of the Mediterranean Sea and in Italy, which yields Barbadoes or hepatic aloes. *Aloë Perryi* furnishes Zanzibar or Socotrina aloes, also a transparent pigment valued in miniature-painting, and a rich violet dye.

Aloes, the inspissated juice of the leaves of a number of species of *Aloë,* a genus of the lily family of over 100 species, widely distributed in warm arid regions. The leaves are long, thick, and succulent, and the juice that yields aloes is thin and flows readily from the cut leaf. This is then thickened (inspissated) by natural or by artificial drying, and there results a yellow to brownish to blackish, or greenish, mass of a tarry, waxy, or glassy consistency. The aloes that is used in the United States is either Barbadoes aloes, from *Aloë vera,* or Socotrina aloes, from *Aloë Perryi.*

As a medicine aloes has been used for centuries. It is a powerful cathartic, acting particularly on the large intestine, its active principle being termed *aloin.* Its action is extremely variable, and in large doses it has been known to induce abortion. See CATHARTICS.

Aloes Wood (sometimes called also eagle wood, calambac, paradise wood, or agallochum), the inner part of *Aquilaria ovata* and *Aloes agallochum,* trees of the order *Aquilariaceæ,* natives of the tropical parts of Asia, and supposed to be the aloes or lignaloes of the Bible. They are large, spreading trees. Aloes wood contains a dark-colored, fragrant, resinous substance, and is much prized in the East as a medicine and for the pleasant odor it diffuses in burning.

Alopecia, a partial or complete loss of hair in large quantities. This is due to a number of causes and frequently leads to baldness (q.v.). Alopecia is of two main kinds: primary or secondary. In primary alopecia there may be (1) a congenital lack of hair (this is rare); (2) senile alopecia, due to the advent of old age; (3) premature baldness, this may be a natural product, or it may be the result of a chronic seborrhea, or dandruff (q.v.).

Aloysius Gonzaga, Saint: b. in Lombardy 1568. At the age of 17 he transferred his inheritance and right of succession to his brother Rudolph and immediately set out for Rome. Here he entered the novitiate of the Society of Jesus, and shortly after began his studies in the Roman College. While nursing the victims of a contagion then ravaging the city he contracted the disease, which carried him off in his 25th year. His brief career was characterized by such extraordinary virtue that he was canonized a saint by Pope Benedict XIII. in 1726, and is now recognized by the Catholic Church as the Patron of Young Students. His feast day is celebrated June 21.

Alpaca, or **Paco** (Ar. *al*, the; Peruv. *paca*), a semi-domesticated animal (*Lama pacos*), native to the Andes and valued for its wool. It is a cameloid mammal, closely allied to three others of the same region, the vicuña, the llama, and the guanaco; but it much resembles a sheep, except in the length and erect carriage of its head. The natural growth of its thick woolly hair would be about two feet, but it is clipped, the annual growth being about eight inches. In color the wool varies from pale yellowish brown or gray to black; its fibre is straighter than that of sheep wool, and very fine, glossy, and elastic. The animal is now seldom seen in an entirely wild state. See LLAMA.

Alp-Arslan ("strong lion"), the greatest ruler of the Seljuk Turks: b. Turkestan, 1028; d. Berzern 1072. He succeeded his uncle Togrul 1063, consolidated his realm into one kingdom, and then proceeded to a career of conquest interrupted only by his death. He conquered central Asia to the Oxus; and invading Armenia and Georgia, in August 1071, he overthrew and captured the Emperor Romanus IV. (Diogenes) in a bloody battle near Malaskerd, between Van and Erzerum, and only released him on payment of a vast ransom. He was assassinated while invading Turkestan and was buried at Merv.

Alpena, Mich., a city and the county-seat of Alpena County, 110 miles north of Bay City; on the west side of Lake Huron, at the head of Thunder Bay, on the Detroit and Mackinaw Ry. It is divided in two by Thunder Bay River.

Industries, etc.— There are extensive manufactures of paper from wood-pulp, and of cement from limestone and clay. Further establishments include two large tanneries, large extract works (hemlock) for export trade, two foundries and machine shops, five saw-mills, 20 shingle-mills, two veneer-mills, a woolen-mill, two flour-mills, three large sash and blind factories, two large excelsior-mills, quarries, and two stave and heading factories. The harbor facilities are excellent.

Public Institutions, Buildings, etc.— There is a public library and a park system. Lutherans have three church edifices; Catholics, three; Methodists, two; Congregationalists, one; Presbyterians, one; Episcopalians, one; Baptists, one; Seventh Day Adventists, one; Jews, one; Free Methodists, one; Church of Latter Day Saints, one; and Non-Sectarians, one. The three banks have a combined capital of $250,000, with an annual business of $2,500,000.

History and Government.—Alpena was settled in 1835, and was incorporated in 1871. It is governed under a revised charter of 1897 by a mayor, biennially elected, and a council of 12 members, elected annually. The mayor has no power of appointment. Pop. (1904) 12,400.

MICHAEL O'BRIEN.

Alphabet (from *alpha* and *beta*, the first two letters of the Greek alphabet), the ordinary series of the letters or syllables (in syllabic alphabets) of a language. For an account of what is known or conjectured of the origin of alphabetic and other systems of writing, see WRITING. The English alphabet, like the most of those of modern Europe, is derived directly from the Latin, but owes its ultimate origin to the Phœnician, which gave birth also to the ancient Greek, the Etruscan, the Gothic, etc. According to tradition the Phœnician Cadmus introduced writing into Greece, the letters first used being the same as the Phœnician, but afterward undergoing changes both in sound and form. It would appear that the Phœnicians themselves borrowed their alphabet from the hieratic alphabet of Egypt, whence also the Hebrews may have obtained theirs during their long stay in that country, though it is more probable that like others they were content to receive it at second-hand from the Phœnicians. The Hebrew alphabet now employed is not the original one, but has an Aramaic origin, having been adopted some time after the Captivity. The Hebrew alphabet proper, as we find it on ancient coins, is evidently the same as that of the Phœnician inscriptions. The names of the letters in Phœnician and Hebrew must have been almost the same, for the Greek names, which, with the letters, were borrowed from the former, differ little from the Hebrew. By means of the names we may trace the process through which the Egyptian characters were transformed into letters by the Phœnicians. Some Egyptian character would, by its form, recall the idea of a house, as for example, in the Phœnician or Hebrew *beth*. This character would subsequently come to be used wherever the articulation *b* occurred, whether in the beginning, middle, or end of a word. Its form might be afterward simplified, or even completely modified, but the name would remain, as *beth* still continues the Hebrew name for *b*, and *beta* the Greek. Our letter *m*, in Hebrew called *mim*, water, has still a considerable resemblance to the zigzag wavy line chosen to represent water, as in the zodiacal symbol for *Aquarius*. The letter *o*, of which the Hebrew name means eye, was originally intended to represent that organ. From the ancient Greek alphabet are generally derived in a direct line the ordinary Greek alphabet, the Latin, and the Etruscan, though the last may have been directly derived from the Phœnician. The later Greek alphabet furnished elements for the Coptic, the Gothic, and the old Slavic alphabets. The Latin characters are now employed by many nations, such as the Italian, the French, the Spanish, the Portuguese, the English, the Dutch, the German, the Hungarian, the Polish, etc., each having introduced such modifications or additions as are necessary to express the sound of the language peculiar to it. The Greek alphabet originally possessed only 16 letters, though the Phœnician had 22. These were the five vowels, α, ε, ι, ο, υ, (*a, e, i, o, u*, as in French), and the 11 consonants, β, γ, δ, κ, λ, μ, ν, π, ρ, σ, τ (*b, g, d, k, l, m, n, p, r, s, t*). According to one tradition, Palamedes, a contemporary of the Trojan war, invented ξ (*x*) and the three aspirates θ, φ, χ (*th, ph, ch* guttural). To Simonides was attributed the invention of the double consonants ζ and ψ (*ds* or *z*, and *ps*) and the two long vowels η and ω (*ē* and *ō*), which completed the Greek alphabet of 24 letters as still used. Besides these, there was anciently the *digamma*, a character corresponding pretty nearly to *v*, which afterward slipped out of the Greek alphabet; and the character ' representing an aspirate at the beginning of words. The original Latin alphabet, as it is found in the oldest inscriptions, consisted of 21 letters; namely, the vowels *a, e, i, o*, and *u* (*v*), and the consonants *b, c, d, f, z, h, k, l, m, n, p,*

q, r, s, t, x. *Z* slipped out at an early period, and *g* took its place. To these we might also add the characters *æ* and *œ*, representing the Greek dipthongs *οι* and *αι*. The letters *ι* and *u*, it must be remarked, had a double force, that of a vowel and that of a consonant. In the latter case they were, after the introduction of printing, changed frequently into *j* and *v*. The *i* consonant, as in *iuventus* (youth), had a sound resembling that of *y* in English or *j* in German; *u*, consonant, as in *uespa* (*vespa*), a wasp, had a sound much like the English *w* — *wespa*. (At least this opinion appears best supported by the evidence.) No genuine Latin word contains either *y* or *z*, these being used in foreign (chiefly Greek) words adopted into the language; and *k* is found in classical Latin only in *Kalendæ*. While the alphabets of the west of Europe are derived from the Latin, the Russian and other Slavonic alphabets of the East come from the Greek. The modern Russian, consisting of 35 letters, is a modification and simplification of the ancient Cyrillic alphabet, invented by Cyril in the 9th century in order to translate the Gospels into the language of the Slavs of Bulgaria and Moravia. It was formed of Greek letters, together with some borrowed from the Armenian and Coptic alphabets, themselves descended from the Greek. The Anglo-Saxon alphabet (see ANGLO-SAXONS) had two letters for the two sounds of *th*, which appear to have come from the Greek through the Mœso-Gothic, and which were unfortunately not retained in later English. It wanted the letters *j, k, q, v, z*, but it had the sound *æ*. The German alphabet consists of the same letters as our own, the common German characters being mere modifications of the Roman, but the sounds of some of them are different. Anciently certain characters called Runic (q.v.) were made use of in Germany and Scandinavia, to which some would attribute an origin independent of the Greek and Latin alphabets. Among Asiatic alphabets the Arabian has played a part exactly analogous to that of the Latin in Europe, the conquests of Mohammedanism having imposed it on the Persian, an Aryan language; the Turkish, a Tatar language; the Hindustani, also an Aryan language; and even the Malay. It consists of 28 letters, and appears to derive its origin from the Sinaitic alphabet, employed during the first centuries of the Christian era, and found in inscriptions in the Sinaitic peninsula, at Petra, in the Hauran, etc. The Sanskrit or Devanagari alphabet is one of the most remarkable alphabets of the world. As now used it has 14 characters for the vowels and diphthongs, and 33 for the consonants, besides two other symbols. The vowel *a* short is to be understood after every consonant, unless excluded by another vowel immediately attached to the consonant. (See SANSKRIT; also articles on the various languages and letters.) Our alphabet is by no means a perfect instrument for what it has to perform, but is both defective and redundant. It is estimated that there are 42 sounds in the language, and only 26 letters to represent them. *A*, to begin with, has to do duty for at least four different sounds, as in *far, fat, fall*, and *fame; o* has three sounds, as *not, note*, and *move; e* has a long sound and a short, as in *mete* and *met*. *C* is a useless letter altogether, since it has always either the sound of *s* or of *k*. Others of the consonants encroach upon each other's provinces; *g*, for example, sounds sometimes like *j*, as in *digest; f* sounds *v* in *of; s* sometimes usurps the sound of *z*, as in *raisin*, sometimes that of *zh* or *sh*, as in *pleasure*.

Alphonsine Tables. See ALFONSO X.

Alphonsus dei Liguori, Saint: b. Naples of noble parents at the end of the 17th century. At the age of 16 he took his degree of Doctor in Civil and Canon Law in the University of Naples and immediately entered the legal profession. This he soon abandoned in order to become a priest and to dedicate his life to the service of the poor in the villages of southern Italy. To assist him in these labors of teaching the poor peasants, he founded the Congregation of the Holy Redeemer, whose members are commonly known to-day in the United States as "Redemptorists." He was made bishop of Saint Agatha by Clement XIII. After 25 years of fruitful labor in this field, he returned to his monastery at Nocera, where he died in 1787. His virtues and learning have made him one of the best known saints in the Catholic Church. He was canonized in 1839 by Gregory XVI., and in 1871 was proclaimed by Pius IX. a Doctor of the Universal Church. His writings deal chiefly with moral theology in theory and practice. His feast is celebrated on 2 August.

Bibliography.—The first authoritative work on Saint Alphonsus was written by one of his scholars, P. Tannoiaand, and is entitled 'Vita ed Instituto del Venerabile Servo di Dio' (3 vols., Naples 1802). In French, an exhaustive work in 4 vols. by Cardinal Villecourt, 'Vie et institut de Saint Alphonse de Liguori' (1863); in English, vid. Butler's 'Lives of the Saints,' and 'Life' by Bishop Mullock.

Alpine Clubs, organizations for the exploration and study of mountains. The original club is the famous Alpine Club of England, organized in 1858, which publishes the 'Alpine Journal.' The first American Alpine Club was organized in 1873. There are in the United States the "Mazamas" and Sierra clubs on the Pacific coast, and the Appalachian Club on the Atlantic. See MOUNTAIN CLIMBING.

Alpine Plants, plants indigenous to high altitudes. The most striking features common to them all are adaptations to rigorous climate such as the dwarfing of the stems of trees and shrubs, but not of roots or flowers, which may even be increased in size over similar plants grown in milder places; gnarled and crooked habit; horizontal or creeping rather than upright growth (the height of the taller species indicating the approximate depth of snow); and the development of structures that tend to check evaporation. Of these last a thickened epidermis, as in conifers, and epidermal hairs, as in edelweiss, are the most striking.

Alps, the most remarkable and interesting system of mountains in Europe. It covers a great part of northern Italy, several departments of France, nearly the whole of Switzerland, and a large part of Austria, while its extensive ramifications in Italy, Germany, Turkey, with its principalities, and Greece, connect it with nearly all the mountain systems of Europe. The name is derived from the Celtic *alb*, which by some is made to signify white, by others height. In the immediate neighborhood of the

mountains *alp* has a peculiar meaning, and signifies one of the high pastures for which the Alps are distinguished. This great congeries of mountains may be said to be included between lat. 44° and 48° N.; and lon. 5° and 18° E. The culminating peak of the whole system is Mont Blanc, 15,781 feet high, though the true centre is St. Gothard, or rather the mountains between the sources of the Rhone and the Inn, and the Swiss cantons Valais, Bern, Uri, and Grisons on the north; and canton Tessin, and Lombardy and Sardinia on the south. It is a curious fact that its great central mass is nearly equidistant from the pole and from the equator. From its slopes flow, either directly or by affluents, the great rivers of central Europe, the Danube, Rhine, Rhone, and Po. Round the northern frontier of Italy the Alps form a remarkable barrier, shutting it off at all points from the mainland of Europe, so that, except in the valley of the Adige, where a remarkable break occurs in the chain, or at the opposite extremity at Nice, it can only be approached from France, Germany, or Switzerland, through high and difficult passes. Accordingly nearly all the great passes of the Alps are connected with roads from the northern kingdoms into Italy.

As usual with mountain systems of great altitude, the highest peaks of the Alps are reached by a gradual ascent through a succession of outer ranges and elevated intermediate valleys. The total width of the system is therefore always great and can hardly anywhere be measured with precision, opinion varying as to the points at which the outer limits should be fixed. Toward the east, however, the system, while it diminishes in height, becomes more widely extended, some of the transverse valleys extending to 150 miles, while that of the Drave reaches 200. From Bellinzona, in the canton of Tessin, to Altorf, in that of Uri, the distance is 50 miles. The outer range is called by the Italians *Pre-alpi*, by the Germans *Voralpen*. The main chain of the Alps, which commonly determines the watershed of the countries through which it passes, contains some of the highest peaks; but at several points there are extensive ramifications of the system proceeding at various angles from the main chain, and more or less connected with it, and which sometimes exceed in mass and altitude the corresponding parts of the principal chain. Such are the Alps of Dauphiné and Savoy, and the Bernese Alps. The principal valleys of the Alps run mostly in a direction nearly parallel with the principal ranges, and therefore east and west. The transverse valleys are commonly shorter. In the section called the Lepontine Alps, however, long ranges run north and south, forming valleys transverse to the dividing line of the waters, and terminating in the great Italian lakes. The slopes toward the south are more precipitous than toward the north, and as most of the collateral ranges lie to the north of the main chain the great valleys are mostly to be found in the intervals between them. The transverse valleys of the Alps frequently lead up through a narrow gorge to a depression in the main ridge between two adjacent peaks. These are the passes or *cols*, which are found by tracing a stream which descends from the mountains up to its source. The col is usually found to receive the drainage of the neighboring peaks, and when it is of sufficient extent a small lake is generally formed, from which a stream flows down on each side. When the one stream has been traced up to its source the passage across the mountains is completed by following the course of the other. The principal passes, now well known, are more than 50 in number; but there are many others more difficult and dangerous which have never had more than a local reputation.

The common divisions of the Alps have been taken from the Romans, whose acquaintance with the Alps as the northern boundary of Italy was considerable, yet their classification, being formed mostly for practical purposes, was far from complete. Several modern divisions have been added. The Romans were acquainted with many of the best passes, to which from their altitude they gave the name of *Mons*. Before noticing these divisions a glance may be taken at the general direction of the main chain. The most convenient starting-point is on the Mediterranean coast, near Nice. Eastward the chain proceeds along the coast till it forms a junction with the Apennines, which may be considered as one extremity of the system. In the opposite direction it proceeds northwest, and afterward north on the boundaries of France and Italy to Mont Blanc; it then turns northeast and runs generally in this direction to the Gross Glockner, in central Tyrol, between the Drave and the Salza, where it divides into two branches, the more northerly of which proceeds northeast toward Vienna. The southern chain subdivides again, one branch running in a southerly direction, connects itself with the mountains of Dalmatia, and by a southeasterly continuation with the Balkans and the mountains of Greece; the middle branch proceeds toward the Drave and Danube. With these continuations, which lose themselves insensibly in other ranges, the Alps may be considered to terminate.

The Maritime Alps.— The first great division of the Alps extends from their junction with the Apennines to Monte Viso, a distance of about 100 miles. This mountain is the most prominent object from the basin of the Po, wherever the Alps are visible. The division of the Alps from the Apennines has been variously fixed at Col di Tende and Col d'Altare, near Savona. The northern limit of the Maritime Alps is to the south of Monte Viso. The culminating-points are the Aiguille de Chambeyron, 11,155 feet, and the Grand Rioburent, 11,142 feet. The principal pass is the Col di Tende (6,158 feet), which was made practicable for carriages by Napoleon. It leads from Nice to Turin. The road is dreary, but commands a view of the Alps from Col d'Iséran to Monte Viso. There are carriage roads over the Col di San Bernardo and Col di Nava. Numerous tributaries of the Po and the Durance with the Var and other lesser rivers rise in the Maritime Alps.

The Cottian Alps.— Anciently named after a chief of the district, and extending from Monte Viso to Mont Cenis — consist of numerous mountain masses irregularly grouped, the main line running northeast, and the principal ramifications to the west of it. The length is about 60 miles. Modern geographers have distinguished a separate group, divided from the main chain

by the valley of the Durance, which are called the Dauphiné Alps. These contain loftier peaks than the main chain. Principal peaks of the Cottian Alps: Monte Viso, 12,605 ft.; Chardonnet, 12,373; Ciamarella, 12,081; of the Dauphinese Alps: Pic des Écrins, 13,462; La Meije, 13,081; Pelvoux, 12,973. There is a carriage road by Mont Genèvre (6,102 feet) between the valleys of the Durance and the Dora Ripaira, and by the Col de Sestrières (6,335 feet) from Cesanne to Pignerolo. The road by the former, Cesanne to Briançon, was constructed by order of Napoleon. The difficult pass of Col de la Roue, Bardonnèche to Modane, is that supposed to have been traversed by Cæsar in order to attack the Helvetians. The Durance and the Dora Ripaira rise in the Cottian Alps.

The Graian Alps.— From Mont Cenis to Mont Blanc (50 miles long). This group has extensive ramifications in Savoie and Piedmont. The principal peaks are, in the main chain, Aiguille de la Sassière, 12,326 feet; in the Piedmontese group, Grand Paradis, 13,300; in the Savoie group, Grande Casse, 12,780. Mont Cenis (6,765 feet), the most frequented of all the Alpine passes, was crossed by Pepin to attack the Lombards. A carriage road over it was constructed by Napoleon in 1803–10, leading from the valley of the Arc to Turin, and uniting with the road from Mont Genèvre at Susa. A railway now passes through the mountain by a tunnel nearly eight miles long. (See CENIS.) The pass of Little St. Bernard (7,192 feet) lies between the valleys of the Isère and Aosta. It was made practicable for cars by Augustus, but is now only available for mules. It appears to have been the road taken by Hannibal. The Col de Bonhomme (8,195 feet) communicates with the Col de la Seigne (8,327 feet) in the Pennine Alps. They lead by a mule path from Contamines to Courmayeur. The Stura, and Orca, and the Arc and Isère, rise in the Graian Alps.

The Pennine Alps (Celtic, *pen* or *ben*, a hill) is the loftiest range of the whole system, having Mont Blanc at one extremity and Monte Rosa at the other (60 miles). Here also begin the most extensive ramifications of the system, some of the collateral ranges rivaling or exceeding in mass and altitude the main chain. The Alps of Haute Savoie form a northwestern continuation of this range. The northern boundary of the Pennine Alps is the Valais, or upper valley of the Rhone. On the opposite side of this valley, and nearly parallel with the main chain, runs the great range of the Bernese Alps. Here the grandest panoramas of Alpine scenery are exhibited. The great peaks of the two vast ranges are only about 20 miles apart, and between them run transverse ranges presenting innumerable secondary heights. From the Matterhorn (Mont Cervin), between Mont Combin and Monte Rosa, a series of great heights, including the Weisshorn and the Gabelhorn, run to the north. The main range contains Mont Blanc, Monte Rosa, and Mont Cervin, three of the highest peaks in Europe. On the west the Bernese Alps are connected with the Jura range. The principal heights of the Pennine Alps are Mont Blanc, 15,781 feet; Monte Rosa, 15,217; Mischabelhörner (Dom), 14,935; Lyskamm, 14,889; Weisshorn, 14,804; Matterhorn, 14,780. In the Bernese Alps are the Finsteraarhorn, 14,026; Aletschhorn, 13,803; Jungfrau, 13,671. There are bridle passes, the Col de la Seigne, already mentioned, and the Col de Ferret (8,320 feet), on each side of Mont Blanc. The pass of Great St. Bernard is celebrated for its hospice. (See BERNARD, GREAT ST.) It was crossed by Napoleon in 1800, but it is not practicable for carriages. There are several passes, as the Col du Cervin, the Schwarzthor, and the Col du Lys, from 10,000 to 14,000 feet in height. The most easterly pass is the Simplon, 6,595 feet, from Brieg to Domo d'Ossola. It has a carriage road made by Napoleon. This is about 36 miles long and 25 feet wide throughout, and is carried over steep precipices and through six galleries hewn in the rock. The Grande Galerie is 683 feet long. A double railway tunnel, the longest in the world (12½ miles), is being driven through the Simplon. Numerous tributaries of the Rhone rise in the valley between the mountains, and on the Italian side the Dora Baltea, Sesia, and other rivers.

The Lepontine Alps form the continuation of the main chain on the south side of the great valley or depression stretching from Martigny in the Valais to Coire in the Grisons, the western portion of which forms the basin of the Rhone, the eastern that of the Vorderrhein. From this chain branch the northern and eastern extensions of the Swiss Alps beyond the Bernese range, the eastern boundary of which is fixed at the defile of the Devil's Bridge, near Andermatt, crossed by the Reuss. The Lepontine range extends to the Splügen Pass. The line of watershed is generally parallel to the valley of the Vorderrhein; but here, as already noticed, some of the principal ranges run transverse to it, terminating in the great valleys in which lie the lakes Maggiore, Como, etc., fed by numerous tributaries from this and the following division of the Alps. This division forms the great water-parting of the whole system. Within a radius of a few miles from the St. Gothard Pass rise the Rhone, the Aar, the Reuss, the Vorderrhein, the Ticino, the Toccia, and the Maggia. The principal pass is the St. Gothard (6,936 feet), over which pass is a carriage road from Bellinzona to Altorf. Through this mountain mass a railway tunnel more than nine miles long was opened in 1882. The Gries Pass (8,050 feet) conducts from Obergestelen to Formazza. The Bernardin Pass (6,769 feet), constructed by the Swiss government, leads from Coire to Bellinzona. The road from Coire to the Splügen is the same as leads to the Splügen Pass (6,945 feet), through which it proceeds to Lake Como. This route commands the finest views of Swiss scenery in the Grisons. Previous to the construction of the present road by the Austrian government in 1823 it was difficult and dangerous. Marshal MacDonald, who crossed it in 1800, lost a large number of men by avalanches at a gorge in the passage of the Cardinello, which the new road avoids. The carriage road over the Furka Pass from Obergestelen to Andermatt, completed in 1867, affords a fine view of the Schreckhorn and Finsteraarhorn. The peaks here are of less elevation. The highest, Monte Leone, is 11,696 feet; the Piz Valrhein is 11,148 feet, and several are above 10,000. Of the northern ranges Tödi is 11,887; Bifertenstock, 11,237; Scheerhorn, 11,132, and there are many above 10,000.

The Rhætian Alps extend from the Splügen to Dreiherrnspitz, on the borders of Salzburg and Tyrol. The Engadine, or valley of the Inn, divides them into two portions. The chain is also broken by the valley of the Adige. To the south, separated by the valley of the Adda, are the Lombard Alps, while the more northerly continuations embrace the Tyrolese and Bavarian Alps. In the main range are the Piz Bernina, 13,294 feet; Piz Roseg, 12,936; Ortelerspitze, 12,814; in the Lombard Alps, Monte Adamello, 11,832; Presanella, 11,688; and Care Alto, 11,352. The other ranges are inferior in height. Good roads now become more numerous. The Malloya Pass (5,942 feet) leads from Chiavenna, by the valley of the Inn, to Innsbruck, and communicates with the road over the Julier Pass (7,503 feet) to Coire. The Pass of Glurns (4,400 feet), from the valley of the Inn to the Adige, is the lowest pass over the main chain. It joins the road to Milan by the Valtelline, the highest part of which is 9,174 feet. This is a carriage road constructed by the Austrian government for communication with their Lombard dominions. The Brenner Pass (4,588 feet) leads from Verona to Innsbruck. The Brenner is crossed by a railway. The northern ranges are intersected by the Septima, Julier, Albula, and other passes. The Adda, Oglio, Adige, Hinterrhein, Inn, and other rivers, rise in this part of the chain.

Noric Alps.— The main chain of the Alps here divides into different sections, as already mentioned. The northern part of the chain extending to Vienna was anciently called the Noric Alps, while the southern continuations were known as the Carnian and Julian Alps, the names Venetian, Dalmatian, and Pannonic Alps being also in use. The culminating peak of the northern range is the Gross Glockner, 12,405 feet. Farther east the heights are of much less elevation. In Carinthia and Styria two parallel branches called the Styrian Alps enclose the upper valley of the Mur. In this group is the Hafnereck, 10,044 feet. In south Tyrol and Venetia several peaks rise above 10,000 feet. The Carnic Alps run from the frontiers of Tyrol and Venetia to the frontier of Carinthia. They are separated from the northern range by the Gailthal. The height of the southeastern continuations of the Alps rapidly diminishes, and they lose themselves in ranges having nothing in common with the great mountain masses which distinguish the centre of the system. Mount Terglou, near the northwestern extremity of the Julian Alps, has a height of 9,371 feet. The name Dinaric Alps is given to a continuation from Mount Klek through Croatia and along the borders of Dalmatia and Herzegovina.

There are various points of vantage from which extensive views of Alpine scenery are commanded at the expense of a moderate amount of climbing. The Rigi, which can now be ascended by railway, is one of these. There are hotels at the top, 5,905 feet above the level of the sea, and 4,468 above the Lake of Lucerne. A favorite view from hence is to watch the sun rise over the Bernese Alps. The Faulhorn (8,799 feet), southeast of Lake Brienz, commands a near view of the same range. The Becca di Nona (8,415 feet), south of Aosta, gives, according to some authorities, the finest panoramic view to be obtained from any summit of the Alps. From the Gorner Grat (to which there is now a railway from Zermatt), and various points in the valley of Chamonix, particularly the Montanvert, which is visited to see the Mer de Glace, views of various interest are obtained. The most accessible Alpine glaciers are those of Aletsch, Chamonix, and Zermatt.

Climate.— In the lower valleys the mean temperature ranges from 50° to 60°. Half-way up the Alps it averages about 32°— a height which, in the snowy regions, where snow always lies, the average does not attain. But even here the solar radiation produced by the rocks and snow is often so great as to raise the barometer to 120° and even higher. The exhilarating and invigorating nature of the climate in the upper regions of the Alps during summer has been acknowledged by all who have perambulated these romantic scenes. The freshness of the breeze as it comes from the snowy peaks tempered by the rays of a southern sun, enables the traveler, without weariness, to perform distances on foot that at home he would have shrunk from attempting. Notwithstanding, however, the invigorating nature of the climate, the inhabitants of the higher valleys are often afflicted with goitre and cretinism.

Botany and Zoology.— In respect to vegetation the Alps have been divided into six zones. The limits of these depend not on absolute height, but on height modified by exposure and local circumstances. The lowest is the olive zone. This tree flourishes better on sheltered slopes of the mountains than on the plains of northern Italy. The vine, which bears a greater winter cold, distinguishes the second zone. On slopes exposed to the sun it flourishes to a considerable height. The third is the mountainous zone or region. Cereals and deciduous trees form the distinguishing features of its vegetation. The mean temperature about equals that of Great Britain, but the extremes are greater. The fourth region is the sub-Alpine or coniferous. Here are vast forests of pines of various species, which have in many places been inconsiderately cut down, the result being that the valleys have been deprived of shelter and denuded of soil. Most of the Alpine villages are in the two last regions. On the northern slopes pines grow to 6,000, and on the southern slopes to 7,000 feet above the level of the sea. This is also the region of the lower or permanent pastures where the flocks are fed in winter. The fifth is the pasture region, the term *alp* being used in the local sense of high pasture grounds. It extends from the uppermost limit of trees to the region of perpetual snow. The landscape is adorned with numerous shrubs; rhododendrons, junipers, bilberries, and dwarf willows being among the distinctive forms of vegetation. The sixth is the region of perpetual snow. The line of snow appears from a distance to be continuous at a limit which varies, according to seasons and localities, from 8,000 to 9,500 feet, but on approaching this apparently continuous line it is found to be broken up and crossed by patches of brilliant vegetation, the limit of which appears to be want of soil rather than severity of climate. Few flowering plants extend above 10,000 feet, but they have been found as high as 12,000 feet. At this great elevation two

species of quadrupeds may be seen, the bouquetin or wild goat, and the chamois, which delight in heights inaccessible to man. The bouquetin, which has become very rare, scales the most elevated peaks, while the chamois is generally found rather lower, but is never seen in the plains. In summer the high mountain pastures are covered with large flocks of cattle, sheep, and goats, which in winter are removed to a lower and warmer level. The marmot, and white or Alpine hare, inhabit both the snowy and the woody regions. Lower down are found the mole, the wildcat, the fox, the lynx, the bear, and the wolf; but the last two are now extremely rare. The vulture, eagle, and other birds of prey frequent the rugged Alpine rocks, and "the snowy ptarmigan" seeks food and shelter among the diminutive plants that border upon the snow-line. Other kinds of game, including the grouse, woodcock, and partridge, may be found from the upper limit of the woods to the more level and habitable parts below. Several kinds of water-fowl frequent the higher lakes, where excellent trout and other fish are found; but those situated at the greatest elevation are, from their low temperature, entirely destitute of fish.

Geology and Minerals.— The geological structure of the Alps is highly involved, and is far, as yet, from being thoroughly investigated or understood. In general three zones can be distinguished, a central, in which crystalline rocks prevail, and two exterior zones, in which sedimentary rocks predominate. The rocks of the central zone consist of granitic gneiss of various forms, seldom pure granite, gneiss, hornblende, mica slate, and other slates and schists. In the western Alps there are also considerable elevations in the central zone that belong to the Jurassic (Oolite) and Cretaceous formations. From the disposition of the beds, which are broken, tilted, and distorted on a gigantic scale, the Alps appear to have been formed by a succession of disruptions and elevations extending over a very protracted period. The large beds of calcareous rock which overlie the older rocks both to the east and west appear to have been ruptured and rolled back by the upheaval of the central mass. Mining is not carried on to an extent proportionate to the magnitude of the mountain range. Iron and lead, however, are found in considerable abundance, and the Bleiberg (lead mountain) mine, in Carinthia, furnishes the purest lead in Europe. Rock-salt is abundant toward the north of the chain, and the salt-works of Bex in Canton de Vaud, of Hall in Tyrol, of Hallein and of Berchtesgaden in the vicinity of Salzburg, are of note. Mercury exists chiefly in the east part; the richness of the mine of Idria, northwest of Trieste, is well known. Besides those principal products, gold, silver, copper, zinc, alum, and coal are wrought to some extent.

Alsace-Lorraine, äl-säs-lō-rān' (German, *Elsass-Lothringen*), a district occupying the extreme southwest corner of Germany, bounded west by France, east by Baden, and south by Switzerland. Its length from north to south is 123 miles; its breadth varies from 22 to 105 miles; and its area is 5,580 square miles, of which 1,353 belong to Upper Alsace (in the south), 1,844 to Lower Alsace (northeast), and 2,383 to Lorraine (northwest). Pop. (1900) 1,717,451, of whom 76 per cent were Roman Catholics, and more than 80 per cent spoke German — mainly the vernacular Alsatian, a dialect of Alemannian. The most populous districts in their order are Lower Alsace, Lorraine, and Upper Alsace. The French-speaking population is mainly in the larger towns and in Lorraine. The Rhine flows 115 miles north by east, along all the eastern border, and receives, below Strasburg, the Ill from Alsace, 127 miles long. Other rivers are the Moselle, flowing through Lorraine past Metz, and its affluent, the Saar. Along the Rhine is a strip of level country, 9 to 17 miles broad and declining from 800 to 450 feet above sea-level. Westward of this rise the Vosges Mountains, culminating at a height of 4,677 feet; while Lorraine, rather hilly than mountainous, rarely attains 1,300 feet. About 48.5 per cent of the entire area is arable, 11.6 meadow and pasture, and 30.8 under wood. Alsace-Lorraine produces much wine, grain, and tobacco; it is rich in mines, iron and coal; and manufactures iron, cotton, wool, silks, chemicals, glass, and paper. It contains the important cities of Strasburg (pop. 1900, 150,268); Mühlhausen (pop. 1890, 27,538); Metz (pop. 1890, 60,186); Colmar (pop. 1890, 30,411). As a French province, Alsace was divided into the departments of Haut-Rhin and Bas-Rhin. Lorraine fell into the departments of Meuse, Moselle, Meurthe, and Vosges (parts of all which still remain French). The lieutenant-governor (*Statthalter*), representing the imperial government, resides at Strasburg, and is assisted by a ministry of five departments and a council of state.

From the 10th century Alsace-Lorraine formed part of the German empire till a part of it was ceded to France at the Peace of Westphalia (1648), and by the Peace of Ryswick (1697) the cession of the whole was ratified. German never ceased to be the chief language of the people, and all newspapers were, during the whole period of the French possession, printed in both languages. In 1871, after the Franco-Prussian war, Alsace and German Lorraine were, by the Treaty of Frankfort, incorporated in the new German empire. The great mass of the population was strongly against the change, and 160,000 elected to be French, though only 50,000 went into actual exile, refusing to become German subjects. Since the era of the Revolution Alsace in sentiment was wholly French. To France she gave the bravest of her sons — Kellerman, Kléber, and many another hero. Strasburg first heard the 'Marseillaise'; and MM. Erckmann-Chatrian, Lorrainers both, have faithfully represented their countrymen's love of *La Patrie* in the days of the second as of the first Napoleon. Of late it is claimed by the Germans that, through the emigration of the irreconcilables and the immigration of German settlers, the tendency of the old natives to accept the inevitable, and the rising up of a new generation, to whom the French connection is a tradition, the situation has slowly but steadily changed in favor of Germany and the existing firm but fair administration. The irritating passport system, a special grievance not in force elsewhere in Germany, was withdrawn in 1873. On 9 May 1902, Emperor William directed that a bill be laid before the Federal Council abolishing paragraph 10 in the imperial constitution, which imposed practically a dictatorship on the *reichsland* of Alsace-Lorraine.

Alsop, Richard, poet: b. Middletown, Conn., 23 Jan. 1761; d. Flatbush, L. I., 20 Aug. 1815. He studied at Yale, but did not complete his course. He formed the literary group known as the "Hartford Wits," which includes Benjamin Trumbull, Lemuel Hopkins, and Theodore Dwight. Alsop was largely responsible for the 'Echo' (1791–5), a series of travesties and burlesques on current fads and literature (pub. in book form 1807). He wrote 'Monody on the Death of Washington' (1800); the 'Enchanted Lake of the Fairy Morgana' (1808).

Altai (al'tī) **Mountains,** a mountain range of central Asia, extending from the desert of Gobi in a northwesterly direction along the boundary of Mongolia and Sungaria. After passing the Russian frontier it gradually falls off in altitude and merges into the steppes. The rivers of this region are mostly head waters of the Obi and Irtysh. The mountain scenery is generally grand and interesting. The highest summit is Baluka, about 17,500 feet above the sea. The area covered by snow and glaciers is large. The mountains have a severe climate, but agriculture is carried on to some extent in the larger valleys. The inhabitants are chiefly Russians and Kalmuks.

Altaic Languages, a family of languages occupying a portion of northern and eastern Europe, and nearly the whole of northern and central Asia, together with some other regions, and divided into five branches, the Ugrian or Finno-Hungarian, Samoyedic, Turkic, Mongolic, and Tungusic. Also called Ural-Altaic and Turanian.

Altar, the structure on which sacrifices are offered or incense burned as an act of worship. In the Catholic Church, the sacred table on which is offered the Sacrifice of the Mass. The earliest altars were of wood, but Pope Silvester, at the beginning of the 4th century, decreed that the altar should be made of stone, or at least that part of it on which the chalice and host are placed. The ritual of the Catholic Church commands that the altar must be consecrated by a bishop or a mitred abbot who has received the faculties and the relics of a saint to be enclosed in the altar stone, which is placed in the centre of the table of the altar.

Altgeld, John Peter, American politician: b. Germany, Dec. 1847; d. 12 March 1902. Brought to Mansfield, Ohio, in infancy, he received a public-school education; served in the Civil War as a private in the Union army, 1864–65; taught school in Missouri; became a lawyer there and county attorney of Andrew County in 1874. Removing to Chicago in 1875 he became prominent in the Democratic party. An unsuccessful candidate for Congress in 1884, he was judge of the Chicago Superior Court 1886–91. Elected governor in 1892, one of his first official acts was to pardon three anarchists, imprisoned since 1887 (two for life and one for 15 years) for complicity in the bomb-throwing which killed seven policemen in Chicago, 4 May 1886 (see ANARCHISM; HAYMARKET MASSACRE). It should be said that many leading United States citizens had petitioned for their release on the ground of insufficient evidence, an assumption which Judge Gary (q.v.) has vigorously repelled. Altgeld was governor till 1897. He was a prominent champion of free silver and an active supporter of Bryan for the Presidency in 1896 and 1900, and was defeated as independent candidate for mayor, 1899. He was an able speaker, an efficient advocate of prison reform, and appears to have been moved chiefly by sympathy with the working class. He wrote 'Our Penal Machinery and Its Victims,' 'Live Questions,' etc.

Althæa. See HOLLYHOCK; MARSH MALLOW.

Althorp, Lord. See SPENCER.

Altiscope, an instrument consisting of an arrangement of mirrors in a vertical framework, by means of which a person is enabled to overlook an object (a parapet, for instance) intervening between himself and whatever he desires to see, the picture of the latter being reflected from a higher to a lower mirror, where it is seen by the observer.

Altitude, in mathematics, denotes the perpendicular height of the vertex of any plane or solid body above the line or plane of its base; thus the altitude of a triangle is measured by a perpendicular let fall from any one of its angles upon the base, or upon the base produced; therefore the same triangle may have different altitudes, accordingly as we assume one side or another for its base. Again, the altitude of a cone or pyramid, whether right or oblique, is measured by a perpendicular let fall from the vertex to the plane of its base. Similar remarks apply to other solids. In astronomy altitudes are measured or estimated by the angles subtended between the object and the plane of the horizon; and this altitude may be either true or apparent. The apparent altitude is that which is obtained immediately from observation; and the true altitude that which results from correcting the apparent altitude, by making allowance for parallax, refraction, etc. The altitude of a terrestrial object is the height of its vertex above some horizontal plane assumed as a base.

Alton, Ill., city in Madison co., on the Mississippi River, and on the Chicago & A., the Cleveland, C., C. & St. L., the St. Clair, M. & St. L., the St. Louis, C. & St. P., and the St. Louis, K. & N. W. R.R's; about four miles above the mouth of the Missouri River and 15 miles north of St. Louis. Its river lines of transportation include the Eagle Packet Company line, the Diamond line, the St. Louis & Clarkson, and the St. Louis, Naples & Peoria. Alton was settled early in the century, but was not incorporated as a city until 1837. The city, built upon a high limestone bluff, has very picturesque surroundings. The Mississippi River is spanned here by a railroad bridge, and the city is connected by electric railway with Upper Alton, two miles to the northeast, where is located Shurtleff College (q.v.). Monticello Seminary (q.v.) is located at Godfrey, four miles from Alton, on the Chicago, A. & J. R.R.. Alton has in addition to an extensive river and railroad trade, large manufacturing interests. The Illinois Glass Company, manufacturer of glass bottles, is located here, and gives employment to 3,200 persons. The company owns and operates a railroad and uses ¾ of the output of a large coal mine. Some of the other manufactures are flour, shovels and picks, foundry and machine-shop products, and shoes. Among the prominent public buildings are the Hayne's

Memorial Public Library, a Home for Aged Women, the St. Joseph's Hospital, the Ursuline Convent and 16 churches. The city is governed by a mayor and common council elected every two years by the people. There are two national banks, two savings banks, three daily newspapers, trolley systems and electric light. In 1837, Elijah P. Lovejoy (q.v.), the abolitionist, was murdered here. A monument to his memory was erected in 1897. Pop. (1900) 14,210; including North and Upper Alton, 18,000.
D. R. SPARKS,
Pres. of the Sparks Milling Co., Alton.

Alton Locke, a story by Charles Kingsley, published in 1850. It was his first novel, and displayed the author's broad sympathy for the condition of the English working classes. It excited immediate attention, and was an important factor in arousing the upper classes to a realization of their responsibilities toward the less fortunate. The altruism of Locke and his friends, Crossthwaite, Mackaye, Lady Ellerton, and Eleanor, forms an admirable and inspiring feature of the book.

Altoona, Pa., city in Blair County, on the Pennsylvania Railroad, 118 m. E. of Pittsburg. It has an elevation of 1,182 feet above the sea; situated in the midst of a most picturesque mountain region, at the eastern base of the Alleghany Mountains. For many years Altoona has been regarded as the most typical of American railroad towns, for here are located the immense repair shops of the Pennsylvania Railroad, and over 10,000 workmen are engaged in manufacturing and repairing locomotives, passenger coaches, and freight cars. There are other large and important manufactories here, of machinery, agricultural implements, coal-mining machinery, etc. It is also the business centre of a considerable agricultural region. The city contains a public library building, high school, several hospitals, and numerous churches and private schools. The famous Horseshoe Bend, on the line of the Pennsylvania Railroad, is located near the city, and Lakemont Park is a well-known pleasure ground within the city limits. The municipal government is vested in a mayor, city council and subordinate administrative officials, who are elected annually. The city owns the waterworks plant, which was acquired in 1872 at a cost of $680,000, and upon which $20,000 is expended annually. The city's expenses aggregate $250,000 yearly, of which amount nearly $100,000 is expended for schools. The city was founded in 1850 by the Pennsylvania Railroad Company. It was first incorporated as a borough in 1854, and chartered as a city in 1868. During the great railroad strike of 1877, Altoona was the centre of the disturbed section and troops were ordered out to protect railroad property here. It is a growing, thriving city. There are three daily and numerous weekly newspapers. Pop. (1880) 19,710; (1890) 30,337; (1900) 38,973, and estimated (1903) 41,600.

Altoona, or **Allatoona Pass**, a mountain pass in northern Georgia, the scene of a sharp engagement between the Federal troops under Gen. Corse and the Confederates commanded by Gen. French, on 5 Oct. 1864. The losses on each side were about equal.

Altrices, birds whose young come out of the egg in a helpless condition and are reared and fed in the nest. All the higher birds, as thrushes and sparrows, are of this kind. The term is opposed to *Precoces*, a name applied to birds whose young are able as soon as hatched to take care of themselves, as in the cases of game- and shore-birds.

Altruism, a term in psychology and ethics to denote disposition and conduct directed toward the well-being of others. It is contrasted with egoism, or self-seeking disposition and conduct. It is essential to altruism, as well as to egoism, that the good of others, or of self, should be consciously and intentionally pursued. Actions and dispositions which are instinctive, such as maternal instinct, are not, properly speaking, altruistic, nor are the opposite egoistic. It is only when the consciousness of self is sufficiently developed in the child to give rise to a contrast between self and the "other" (*alter*), that the conscious pursuit of the interest of one of them is possible. This is covered by psychologists by saying that real altruism and egoism are always "reflective." Altruism is also applied to the type of ethical theory which bases morality upon generous or altruistic disposition or conduct (in the sense defined above).

Altsheler, Joseph Alexander, American author and journalist: b. Three Springs, Ky., 29 April 1862. He studied at Vanderbilt University and has been connected with the Louisville *Courier-Journal* and the New York *World*. His novels are chiefly on American historical subjects: 'The Sun of Saratoga'; 'In Hostile Red'; 'A Soldier of Manhattan'; 'The Last Rebel'; 'In Circling Camps'; 'The Herald of the West'; 'My Captive'; 'The Wilderness Road'; 'The Candidate' (1905).

Al'um, in chemistry, a general name for a large class of substances, which may be defined as double sulphates or selenates, in which one of the bases is aluminum, chromium, manganese, iron, indium, or gallium, and the other is sodium, potassium, rubidium, cæsium, ammonium, silver, or thallium. The alums all crystallize in cubes or octahedra, with 24 molecules of water, and are all isomorphous, so that when in solution together they cannot be separated by crystallization. In naming them aluminum is understood to be one of the metals present unless the contrary is expressly indicated. Thus "potash alum" is the alum whose formula is $Al_2(SO_4)_3 + K_2SO_4 + 24H_2O$. If aluminum is not present, the metal that replaces it is stated; thus "iron-sodium alum" is the alum whose formula is $Fe_2(SO_4)_3 + Na_2SO_4 + 24H_2O$. When selenium replaces the sulphur in one or both of its positions, the alum is most clearly identified by giving its formula. In addition to the true alums a class of substances known as "pseudo-alums" exists. These also crystallize with 24 molecules of water, but they are not isomorphous with the true alums. $Mn_2(SO_4)_3 + MgSO_4 + 24H_2O$ is an example of this class.

All the alums are soluble in water, and it is probable that all are resolved, at least partially, into their constituents, by solution. It is known that in certain cases (in silver alum, for example) the separation is absolute. All of the alums give an acid reaction when in solution. all have an astringent taste, and all lose their water of crystallization when heated.

The alum of commerce is supposed to be potash alum, the formula of which has been already given. Ammonia alum is sometimes substituted, however, owing to the cheapness of sulphate of ammonia, which is now obtained as a by-product in the manufacture of illuminating gas. Sodium alum is probably not substituted for potash alum to any great extent.

The alums are largely used in the arts, especially in dyeing and tanning, and in the purification of water. Bread made from flour containing a small amount of alum is said to be very white, and partly for this reason and partly on account of the cheapness of the substance, ammonia alum has been largely used in the manufacture of baking-powders. This practice has been condemned and pronounced detrimental to health, however, by nearly all the authorities who have written on the subject.

Alums may be formed by crystallization from the mixed sulphates, or by roasting "alum-stone" (see ALUNITE). Some of them occur native. (See MENDOZITE; TSCHERMIGITE.)

Alum Poisoning.— This poisoning may be acute or chronic, the latter being much more common. In the acute variety, often the result of accidental drinking of a gargling solution, the symptoms are nausea, vomiting, purging, cold clammy skin, small thready pulse, thirst, muscular tremor, followed by a rise in temperature in those that have recovered. The treatment pursued in the case of alum poisoning is to wash out the stomach and use the white of eggs as a chemical antidote.

Alum being so widely employed as a preservative, as a means of clarifying water, and as an adulterant in baking-powders, the question of chronic alum poisoning becomes of great importance. The symptoms that have been most frequently observed in such poisoning are disturbances of digestion and constipation. The question as to its harmful action on the kidneys is not yet decided, but it would seem to be harmful rather than the reverse.

Alumbagh, a domain in India formerly belonging to one of the princes of Oudh, about 4 m. S. of Lucknow, near the road to Cawnpore. It comprised a beautiful palace, a mosque, a temple, and other buildings surrounded by a garden, all in the centre of a magnificent park enclosed by a lofty wall with turrets at each angle. On the outbreak of the Indian mutiny this place was occupied by the revolted Sepoys and converted into a fort. On 23 Sept. 1857 it was captured by the British, then on their way to relieve Lucknow. Leaving a garrison of 300 European troops, together with the sick and wounded and about 4,000 native camp-followers, the main body, under Outram, Havelock, and Neill, pushed on to Lucknow. These generals were unable to send reinforcements, but at the end of November the place was relieved by Sir Colin Campbell. The latter left Sir James Outram, with a force of 3,500 men, to hold the Alumbagh, a task which he successfully accomplished, though repeatedly attacked by overwhelming numbers of the rebels. In March 1858 the garrison was finally relieved. At the foot of a tree within the grounds Sir Henry Havelock was buried.

Alumina (Al_2O_3), the only oxid of the metal aluminum. As found native, crystallized, it is only second to the diamond in hardness. The transparent varieties are the sapphire and ruby, the opaque are corundum and emery, only the corundum being pure. In combination with silica it is one of the most widely distributed of substances, ranking in this respect next to oxygen and silicon. It enters in large quantity into the composition of granites, traps, slates, schists, clays, loams, and other rocks. The hydrated oxid, $Al_2O_3.H_2O$, occurs as diaspore, and with ferric oxid as bauxite. Various aluminates occur in certain gems, as in spinel and chrysoberyl. Alumina may be obtained by adding a solution of ammonium hydrate to purify alum dissolved in 20 parts of water, thoroughly washing the very gelatinous precipitate formed, and then drying it carefully. It may also be prepared by igniting powdered aluminum in air or oxygen. Alumina is a white powder, without taste or smell, and infusible except in the oxyhydrogen flame. It is the basis of porcelain, pottery, bricks, and crucibles; and it has a strong affinity for oil and coloring matter, which causes it to be employed in the state of clays as a cleansing powder, and in a state of purity in the preparation of the colors called lakes, in dyeing and calico-printing. It combines with the acids, and forms numerous salts, the most important of which are the sulphate (see ALUM) and the acetate. The latter salt is formed by digesting strong acetic acid (vinegar) with the newly precipitated earth; but for the use of the manufacturer, by decomposing alum with acetate of lead (sugar of lead), or more economically with acetate of lime, a gallon of which, of the specific gravity 1.050, is employed for every 2¾ pounds of alum. The sulphate of calcium formed falls to the bottom, and the acetate of aluminum remains in solution with an excess of alum, which is necessary to prevent its decomposition. It is of extensive use in calico-printing and dyeing, as a mordant, and is employed in the place of alum, to which it is generally preferred.

Aluminite, a mineral having the composition of a hydrous aluminum sulphate, $Al_2O_3.S\,O_3.\ 9\,H_2O$, occurring in white reniform concretions in beds of clay in Germany, England and other European countries. It is opaque, of earthy luster and fracture, is soft and light.

Alumino-Thermics. The new science called *Alumino-Thermics* is based on the discovery that by producing in a suitable manner the chemical combination of oxygen and aluminum a temperature may be created equal to that of the electric arclight. When this mixture is ignited in one spot the combustion continues throughout the whole mass in a very short time without any supply of heat from outside.

In the crucible after the reaction there are two layers. The bottom one is pure metal of equal weight to, but occupying only one-third of the space of, the top layer, which is now oxide of aluminum, so-called corundum. These two layers whilst still liquid are poured rapidly over the rim of the crucible. It is not difficult to distinguish between the slag which flows first and the brightly glittering overheated metal.

About 50 years ago, attempts were made to apply the reducing properties of aluminum. Without exception the experimenters

heated their compounds externally. The reaction was always so violent that they could only operate with very small quantities. It will easily be seen that to arrive at alumino-thermics on a commercial scale from such a starting point required patient study and assiduous work. The recipes for gunpowder or dynamite sound fairly simple, but it requires more than a mere mixture of the ingredients to obtain any effect sufficient for industrial development.

In all exothermic processes the physical properties of the ingredients, in this case particularly those of the oxides, need considering. Then the methods of manufacture have to be worked out for each case. The applications may be roughly divided into two main divisions, the one concerning the metallurgist, the other the engineer. The latter application may be summarized in the word "welding." The study of the metallurgical application preceded that of the other by a few years.

Among the pure metals produced by the alumino-genetic reaction may be mentioned in the first instance chromium free of carbon. It is used in the manufacture of particular qualities of chromium steel with a limited percentage of carbon, and nowadays hardly any high-speed tool steel is made without it. Pure manganese also produced by this process finds employment in copper and nickel manufacture, and, furthermore, in the production of particular sorts of manganese steel of great strength and great elasticity with 12 to 14 per cent. manganese, used particularly for bolts of machinery exposed to great strains. Pure molybdenum and ferro-vanadium have also lately been put on the market. Ferro-titanium has been in use with a number of steel works for quite a considerable time.

Considering the innumerable details connected with the application of so new and practically unknown a force, it is not surprising that only since a few years the process has been introduced on a large and commercial scale. The most important of these welding processes is the one by which a continuous rail — a necessity of modern trolley-road construction — is simply, cheaply and effectively obtained. The marked advantage enjoyed by this system is the absence of any bulky equipment; a crucible, a mould box, and, in some rare instances where a complete butt weld of the head of the rail is desired, a rail-clamp is all that is required. All these materials, including the necessary quantity of thermit, can easily be moved on a hand truck. Each weld, according to the section, requires from 15 to 20 pounds of thermit, and the metal welded around the joint will only weigh, therefore, from 8 to 10 pounds.

The thermit reaction takes place in a crucible which rests on a simple iron stand, that can be attached to the rails or rail-clamps where such are used. The crucible consists of a sheet-iron mantle lined with magnesia or corundum slag, which is tamped round a sheet-iron conus suspended in its middle. The bottom is formed by a hard magnesia stone provided with an exchangeable outlet which will stand 9 or 10 runs. The life of the crucible itself is about 25 reactions; the wear and tear will amount, therefore, to only a few cents per joint. The crucible is plugged by inserting two asbestos washers covered by a metal disk over the outflow or thimble. In the latter is suspended a piece of iron wire, the lower end of which projects below the base of the crucible. This is driven up by a sort or spade and so "taps" the crucible. The heat of the thermic reaction might in spite of the asbestos washers burst through the plugging material. To prevent this the metal disk is further covered by a layer of magnesia sand. The thermic is then poured into the crucible from bags containing the necessary amount for each section. After the charge in the crucible has been ignited in the usual way the reaction takes its course and the crucible is tapped to allow the liquid steel to flow into the mould.

The mould is made according to a special design for each section. Its two parts, one on each side, exactly fit and firmly enclose the rail. It must be dry and porous. On a large scale moulds can be made by manufacturers of refractory earthenware or by railway lines, according to their requirements, in their own shops, by tamping an ordinary mixture of loam and sand in equal parts into a sheet-iron case placed over the model. This sand mould must be dried during a couple of hours at a temperature of about 100° C. Before placing the mould round the joint, the rail ends must be cleaned of dirt and rust with a wire brush and slightly warmed. In case the tops of the rails are to be butt-welded the sections must be filed. The great heat of the liquid thermit steel literally melts and amalgamates the ends of rails projecting into the moulds, making them as one, so that when cool it leaves a continuous rail. The joint, if anything, is stronger than an equal section of the rail, from the fact that a shoe or collar is left around the rail at the joint of thermit steel.

As the whole heating of the rail ends is a uniform one, and the same is done without exposure to the atmosphere; and as the final cooling is done under the same conditions as that under which a rail is made, it has been found that there are no changes in the ingredients or temper of the steel in the rail, and it is left just as it was, except that the ends are melted together up to, and generally a little above the bottom of the tread of the rail. If the alignment and surface of the rail at the joint was perfect before making the weld, it will be found to be the same after, except that a slight longitudinal expansion has taken place, caused by the heat; and all of this is to the benefit of the joint, for with the heat it tends to butt-weld the heads; in fact, it does so if the rail ends touch each other when the weld is made.

The cost of relining crucibles and moulds amounts to but a few cents per joint, and experience shows that the item of labor per joint should not run over 15 cents. The system can be applied on short lines with the

same economy as on long ones, for it is only a question of the number of men, and consequently the number of joints required per day. It is especially an ideal system for repairing old worn joints, for but little paving need be taken up (sufficient to take off the old fishplate), and in a few minutes a joint may be raised and welded, and that would prolong the life of an old track for many years. The strength of the weld is about 80 per cent. of the strength of the original material. The shoe welded on to the foot of the rail not only makes up for the remaining 20 per cent., but materially strengthens the rail at the joint.

The so-called third rail is also welded by this means. The skin resistance of copper bonds increases with time, and frequent repairs are necessitated thereby. Welding obviates these repairs. It can be done in two ways. The first is identical with the one described (but without the use of clamps), and is now in extensive operation. The second consists in welding a small bridge of thermit iron between the feet on one side of the rail. The other side of the joint, where there is no thermit-welded bridge, is mechanically strengthened by an ordinary light fishplate. In this case the crucible is superflous. The welding portion of about three pounds only is placed directly into the upper part of the mould, which is prolonged by a piece of gas pipe.

The question of the continuous rail with exposed T rails on railroads is not solved at present for want of sufficient tests. Of course, welding is the only means by which a continuous rail, properly speaking, can be obtained with exposed rails. That it is practicable within certain limits and that it is desirable to have greater lengths of exposed track welded together is admitted by permanent-way engineers. The question is being investigated at present, but some time must elapse before a definite opinion can be arrived at. In any case exposed rails can undoubtedly be welded without any risk in tunnels and subways, where differences of temperature are very slight, and contraction and expansion therefore only minimal.

Steel girders for construction work can, of course, be welded in the same way as rails. For really solid jointing equal to the strength of the girder itself, welding is necessarily cheaper than riveting. Considerable work of this kind has already been done in Germany, but in Europe there are few of the wonderful steel-girder constructions which so greatly impress the European on his arrival in this country. There is a wide field for this work in the United States as soon as the preparatory experiments and calculations have been made and officially sanctioned.

The result of the reaction in the crucible is a liquid iron, which sinks to the bottom, and an aluminum slag that swims on the top. Whoever has a supply of thermit and ignition powder has a supply of liquid mild steel, which, on account of its low contents of carbon, 0.1 per cent., is very malleable and ductile. Foundries can correct faulty castings, machine shops can mend broken or worn out parts, and last, but not least, marine engineering works can repair large steel castings, such as crank shafts, and particularly broken sternposts. The weld can either be effected by running the thermit iron round the ends of the piece in the shape of a ring, or by both running it between and around at the same time.

The mould must be made of sand and loam in equal parts, or one-third sand and two-thirds china clay. It must be absolutely dry. Thermit steel being much hotter than steel out of a furnace, the mould must have no trace of moisture. Dry first gradually and then in the furnace to dull red heat. The quality of the thermit steel may be adapted to various requirements by mixing small, clean iron punchings, or the like, into the thermit powder. For 5 to 10 pounds or more an admixture of 5 to 10 per cent. of punchings will not make the overheated steel lose the property of melting and fusing with the metal with which it comes in contact. The proportion of punchings may be increased considerably (even 20 to 25 per cent.) for larger operations. Iron or steel punchings will moderate the temperature of the reaction, and increase, of course, the quantity of the metal available for the weld.

The most startling, and at the same time, the most effective work done in the way of repairs by the thermit is in connection with marine engineering. To weld broken sternpost of large trans-Atlantic liners, or crankshafts, or similar pieces, crucibles of six feet in height, with a capacity of seven to eight cwt., have been constructed. The reaction in these hardly takes longer than in a small crucible. The enormous advantage offered to steamship owners by such repairs will be apparent when it is remembered that a broken sternpost would otherwise have to be replaced by a new one. Besides this expense, the one incurred through loss of time, the steamer being laid up in dry dock for many weeks in order to have the new part fitted in, is very heavy indeed.

In nearly all experiments the thermit is ignited in a crucible so as to allow the liquid steel to flow out independently from the much lighter slag. The slag is not used in welding solid pieces, except as an additional reservoir of heat. The slag, however, has the peculiar property of adhering instantly in a thin layer to any cold metal object with which it comes in contact. Were thermit to be ignited directly on a piece of metal, the slag would get in between the liquid steel and the object to be operated upon, and would prevent the fusion of the two metals, which is essential for a good weld.

An application where thermit may be ignited on the object, is in repairs of broken roll bosses. The roll is firmly fixed so that the welding surface lizes horizontally. The mould carries on its inside, suspended by an overlapping rim, an iron ring of one-half inch diameter. After this mould and ring are firmly fixed one-half inch of liquid cast iron or cast steel is poured on the welding surface. On this the thermit powder is

poured and ignited. About 30 to 40 pounds are taken for the superficial foot. This will soften the metal to a depth of about two inches. As soon as the reaction is finished the thermit must be well stirred. The slag, on account of its low specific gravity, will thus be driven to the surface, and will cling to the iron ring which is suspended in the mould. After a few minutes more liquid steel is added from the ladle held in readiness, and after thoroughly stirring the contents of the mould the iron ring is lifted out, and all the slag will be found adhering to it. This repair is in common use with the largest works in Germany.

The property of the slag of adhering in a thin refractory layer to any metal surface leads to an application of the thermic process where it plays the leading part — that is, in welding wrought-iron pipes. Of course, the heat of the iron, if applied direct, would destroy the thin walls of any pipe. But as the slag is absolutely refractory to liquid steel, it replaces in a way the steel for the purpose of welding. The *modus operandi* is changed in some essential particulars. The reaction takes place in a crucible with a solid bottom; a small quantity of thermit only is ignited at first, and to this more is added as the mass subsides, and finally the contents are poured over the lip of the crucible in order to direct the slag, and not the iron, onto the thin walls of the pipe. To butt-weld the pipes, the ends must be made to fit accurately on to each other, and must be made bright with a file or emery paper. The two pipes are then firmly pressed together by the clamping apparatus, and the sheet-iron mould, well surrounded with moist sand, is attached. Welding temperature will take place within a minute or two after pouring. The clamps then want tightening one turn of the screw, and the weld is completed. The mould box is removed almost at once, and can be used several times.

The surrounding mass, containing the iron between layers of slag, like the yolk in the white of an egg, is easily removed with a hammer. Such welds will stand pressure of hundreds of atmospheres — as a matter of fact, as much as the pipe itself. About 30,000 to 40,000 pipe joints have been welded by this method, the advantages of which are, shortly, that the operation can take place anywhere without removing the pipe from its position, and that it is cheaper than a solid flanged joint. The dimensions of the mould have been carefully worked out and tabulated for every size of wrought-iron pipe up to six inches diameter. The thermit used for pipe welding is of slightly different composition to the one for welding solid pieces. Besides these there are two other kinds of thermit, chiefly distinguished by the greater plasticity of their slag. One of these, so-called "white thermit," is used for annealing locally the plates of armor-clads, which are hardened to such an extent by carburization as to prevent any tools being used on them. Such armor plates can be easily softened by applying to the hardened surface a layer of thermit slag with thermit steel at the back of it.

For cast iron, and in some cases for steel, a special thermit is used which gives off an alloy of iron and titanium so that the titanium enters the liquid metal. This is introduced below the surface of the bath by fastening the box containing the thermit to a shank and holding it down on the bottom of the ladle. The reaction takes place all through the contents of the ladle and thoroughly stirs them up in the space of a minute or two. Gases and particles of slag are driven upwards, so that the fluidity of the iron is increased. The proportion of added thermit is only one-quarter to one-sixteenth per cent. of the total contents of the ladle. The effect of the titanium is to bind small quantities of nitrogen to increase the fluidity of the cast iron, and to produce a finer grain.

Another application of the "box-reaction" is important for steel castings, and especially for casting large steel ingots, to prevent the familiar phenomenum of piping. In the heads of such blocks hollow spaces are found which mostly cause 30 to 40 per cent. of loss. The thermit process as used for this purpose consists in introducing a box of anti-piping thermit into a block with aid of an iron rod. The box is introduced, of course, only after the piping has been formed. The head layer, which has already become solid, is broken through for this purpose. Immediately after the reaction is completed, steel which is held in readiness for this purpose is poured into the open hole. The method is really very simple, and one learns very quickly at which time to introduce the box. Moreover, it is very cheap, only about 10 pounds of thermit being required for blocks of 20 tons weight.

The simplest, and at the same time, most effective application of thermit in foundry practice is the following: Wrap thermit in a paper parcel and throw it on the liquid metal as it rises in the riser. The liquid metal will be revived at the point where it is most liable to chill, and the well-known troublesome shrinkage cavities will be avoided. When applied to cast iron the paper must contain some ignition powder at the bottom; with steel this is unnecessary.

EDWARD S. FARROW,
Consulting Railroad and Mining Engineer.

Alu'minum, a lustrous, nearly white metal, widely used in the arts. Its existence was recognized by Davy, although he did not succeed in isolating the metal. Davy gave it the name "alumium," and afterward "aluminum."

The name is derived from the Latin word *alumen*, signifying "alum"; but the Romans and the Greeks had no very exact knowledge of chemistry, and *alumen* and its Greek equivalent were used to designate a variety of substances whose one common property is an astringent taste. The substance now called alum was in all probability included among them, for it was well known to Geber. Alum was long believed to be of the same nature as the vitriols, until Paracelsus announced that the vitriols contain metals, while alum (he said) does not contain a metal, but derives its properties from an "intermixture of the earths." It was long believed that the earth contained in alum is of a calcareous or lime-like nature; but in the 17th century it was noticed that an alum may be obtained by treating clay with sulphuric acid, and in a

treatise published in 1746 Pott stated that the earth forming the base of alum is of an argillaceous or clay-like nature. Eight years later, in 1754, Marggraf announced that alumina, the earth (now called the oxid) of alum, is entirely different from lime, and that it exists in clay, combined with silica. At the beginning of the 19th century alumina was generally admitted to be the oxid of some metal and Sir Humphry Davy and other chemists endeavored to decompose it and obtain the metal itself. They were unsuccessful, however, and the isolation of aluminum was first accomplished by Wöhler in 1827, by heating the chloride of alumina with metallic potassium. The potassium abstracted the chlorine and thereby set the aluminum free. Paracelsus was wrong in asserting that the base of common alum is not a metal, but his error was due to his pardonable ignorance of the fact that all the so-called "earths" are oxids of metals.

The new metal proved to be most remarkable. Although it had so powerfully resisted all the earlier attempts to separate it from the oxygen with which it was combined, yet, when the separation had once been effected, it was found that the metal exhibits no very marked tendency to oxidize, even when heated in oxygen. It is nearly white, but has a slightly bluish tinge. It is about as hard as silver and is very malleable and ductile. It can readily be drawn out into wire or beaten into leaf. It takes a good polish, especially when alloyed with about three per cent of silver. It has a tensile strength about equal to that of copper, and a specific gravity of only about 2.6. It melts at about 1,300° F., its specific heat is 0.221, its coefficient of expansion (Fahrenheit scale) is 0.00129, and its atomic weight is 27.1. Bars of the metal emit a very musical sound when struck, but it is said that a bell made of it "sounds like a cracked pot." Aluminum is very feebly magnetic. It is scarcely affected by nitric acid, though hydrochloric and sulphuric acids will dissolve it, and it is entirely unaffected by sulphur, except at high temperatures. Solutions of caustic potash or soda, however, dissolve it readily, with evolution of hydrogen.

Aluminum is exceedingly abundant in nature, for next to oxygen and silica it is the chief component of the earth's crust. Feldspar and mica contain it in considerable quantities, as well as common clay, which is formed by the disintegration of feldspar. The oxid of aluminum occurs in many beautiful forms, giving us the ruby and the sapphire, besides forming an essential part of the garnet, topaz, turquoise, and emerald. Corundum and emery, which are almost indispensable for grinding and polishing purposes, are also forms of the oxid. Kaolin, used in the manufacture of porcelain, is a very pure silicate of aluminum. The beautiful lapis-lazuli contains a considerable proportion of aluminum; and ultramarine blue, formerly obtained by pulverizing lapis-lazuli, is now prepared artificially from kaolin, together with other substances. The red color of the ruby is due to a trace of certain chromium salts, and the blue of the sapphire is probably due to a trace of some compound of cobalt. By melting oxid of aluminum in the oxyhydrogen blow-pipe flame, adding a slight amount of certain metallic oxids, and cooling again, artificial rubies and sapphires have been made which are indistinguishable from the natural gems, except to the eye of an expert.

Although aluminum is far more abundant than tin, copper, lead, zinc, or iron, it can be extracted from the minerals in which it occurs only with the greatest difficulty. Until very recently the aluminum of commerce has been prepared by substantially the method first given for its isolation by Wöhler, the chief difference, aside from matters of practical detail, being the substitution of metallic sodium for the more expensive potassium. At the present time, however, practically all of the aluminum that is produced is obtained by electrolysis. Prof. C. F. Chandler describes the Hall process (which differs from the Heroult process only in its details) as follows: "It was a remarkable fact, after all the attention that had been devoted to the subject of aluminum by St. Claire Deville and other chemists, that it remained for a young graduate of Oberlin College, Charles M. Hall, to devise the process by which all the aluminum in the world is now manufactured. It occurred to young Hall, whose attention was drawn to the subject while he was still a college student, that some way might be found for extracting aluminum by electrolysis. Satisfied that it would be impossible to employ an aqueous solution, he sought for other solvents, and finally discovered that a melted bath of the double fluorides of aluminum and metals more electro-positive than aluminum (such as sodium or calcium) is a perfect solvent for alumina, taking it up as promptly as hot water takes up sugar, and dissolving as much as 25 per cent of its weight. Having thus found an anhydrous solvent for alumina, the next step was to ascertain whether the solution would yield up the aluminum promptly to electrolysis." The most gratifying success attended these further experiments, and the practical details of the process were worked out at Kensington, Pa. The vessels or pots employed in the making of aluminum by this method are rectangular iron boxes, thickly lined with carbon, which constitutes the cathode. The anodes consist of 40 cylinders of carbon, each about 3 inches in diameter and 18 inches long when new. These are supported above the pot, dipping into the bath of melted fluorides. No external heat is employed, the heat developed by the resistance to the current being sufficient to maintain fusion. Alumina is added from time to time as required, and the process goes on quietly. The resistance of the bath is low when charged with alumina, but it increases fourfold the moment the alumina is exhausted. An incandescent lamp, connected with each bath in parallel, emits no light while the resistance of the bath is low, but the moment the resistance is increased by the exhaustion of the alumina the lamp begins to shine and the workmen hasten to stir in a fresh supply of alumina. The process is continuous, and it is only necessary to keep the baths supplied with alumina and to draw off the metallic aluminum from the bottom of the pot from time to time. Each pot produces about 100 pounds of aluminum, 99 per cent pure, per day of 24 hours.

The electric resistance of aluminum is about twice that of copper, but owing to the lightness of aluminum and its constantly diminishing price (about 30 cents a pound in 1902) it bids

fair to be a serious rival of copper in the transmission of electricity. Many long lines of aluminum wire have been installed in the West. One of the most interesting, in the East, is a line used to transmit power to Hartford, Conn., from a point on the Farmington River, about 12 miles distant. Three aluminum cables are used, containing over 60,000 pounds of metal. The line was designed for 20,000 volts, and it is said that in this instance the use of aluminum instead of copper has proved an entire success, both electrically and financially.

The most valuable property of aluminum is perhaps the facility with which it alloys with most other metals except lead. It has been alloyed with bismuth, calcium, copper, chromium, gold, iron, magnesium, manganese, mercury, molybdenum, nickel, platinum, silver, sodium, tin, titanium, tungsten, and zinc. Some of its alloys with gold are very beautiful, and it has been proposed to use one of them in the manufacture of coins. An alloy with nickel called "nickel silver," promises to be useful in the future, as it is strong and easily worked and has a beautiful white lustre that will not tarnish. The most useful alloys of the metal at present are those with copper, which are known as "aluminum bronzes." The alloy containing 3 per cent of copper is whiter than aluminum; and that containing from 90 to 95 per cent of copper has a color resembling gold. Aluminum bronze is hard and elastic and is not easily affected by chemical reagents. It is much used in the manufacture of articles of all kinds, from cheap jewelry to heavy bearings for machinery. (For information concerning the working of aluminum and other technical points consult J. W. Richards, 'Aluminum, Its Properties, Metallurgy, and Alloys,' Philadelphia, 1890.)

Notwithstanding the abundance of aluminum in nature, it is not taken up by plants save by a few cryptogams. The ash of *Lycopodium chamæcyparissus* sometimes contains 57 per cent of alumina, while the ash of oaks, figs, and birches, grown in the same soil, contains none.

Alum-root, the name given in the United States to two plants on account of the remarkable astringency of their roots: (1) *Geranium maculatum*, or spotted cranesbill, is a native of North America from Canada to North Carolina; it has an angular, downy stem, 3-5-parted leaves with deeply toothed lobes, obovate entire petals, the filaments scarcely ciliated at the base; the color of the flowers is a pale lilac. It is employed successfully as a remedy in dysentery among children; the tincture is recommended in cases of ulcerated sore throat, soreness of the gums, etc. The plant contains large proportions of gallic acid and tannin. (2) *Heuchera americana* (natural order *Saxifragaceæ*) is a downy plant with rough scapes and leaves, the latter being on long petioles, 5-7-lobed, toothed; the calyx is 5-cleft, petals undivided, five stamens; the styles are remarkably long. It contains tannin and is used in preparing a wash for wounds, ulcers, etc.

Alum-shale, a slaty rock of different degrees of hardness; color grayish, bluish, or iron-black; often possessed of a glossy or shining lustre. It is chiefly composed of clay (silicate of alumina), with variable proportions of sulphid of iron (iron pyrites), lime, bitumen, and magnesia. It is found abundantly, and from it is obtained the largest part of the alum of commerce.

Alunite, al'ū-nīt, a native subsulphate of aluminum and potassium, having the formula $K(AlO)_3(SO_4)_2 + 3H_2O$, and occurring both massive and in rhombohedral crystals resembling cubes. It is white with a vitreous lustre, with a hardness varying from 3.5 to 4, and a specific gravity of about 2.6. It has been found, in the United States, in California and Colorado. According to Dana it was first called "aluminilite," a name afterward abbreviated to the present form. Alum may be obtained from it by repeated roasting and lixiviation. (Also called alum-stone and alum-rock.)

Alun'no, Niccolo (real name Niccolò di Liberatore), an Italian painter of the 15th century, the founder of the Umbrian School: b. in Foligno about 1430; d. 1502.

Alunogen, a-lū'nō-jen, a native hydrous sulphate of aluminum, having the formula $Al_2(SO_4)_3 + 18H_2O$. It occurs massive, as an incrustation in mines and quarries, and also in delicate fibrous forms. Its hardness varies from 1.5 to 2, and its sp. gr. is about 1.7. It occurs in large quantities in Jackson County, N. C., and near Silver City, N. M.; and it is found in many other parts of the United States in small amounts.

Aluredus, an English historian: b. about 1100. See Alfred of Beverley.

Alva, or Alba, Ferdinand Alvarez de Toledo, Duke of, Spanish statesman and general: b. 1508; d. Thomar, 12 Jan. 1582. He was educated by his grandfather, Frederick of Toledo, who instructed him in military and political science. He commanded under Charles V. in Hungary, and was present at the siege of Tunis and in the expedition against Algiers. His cautious character and his inclination for politics at first led men to believe that he had but little military talent; and his pride being touched at the low estimation in which he was held, his genius was roused to the performance of exploits deserving remembrance. He won in 1547 the battle of Mühlberg against John Frederick, elector of Saxony, and in 1555 was commissioned to attack the French in Italy, and Pope Paul IV., the irreconcilable enemy of the emperor. When Charles V. resigned the government to his son, Philip II., Alva received the supreme command of the army and conquered the states of the Church and frustrated the efforts of the French. Philip, however, compelled him to contract an honorable peace with the Pope, whom Alva wished to humble. He appeared in 1559 at the French court in order to marry Elizabeth, the daughter of Henry II., by proxy, for his sovereign; she had been at first destined for the crown-prince, Don Carlos. About this time the Netherlands revolted, and Alva was entrusted with a considerable army and unlimited power to reduce the rebellious provinces. Scarcely had Alva reached Flanders at the end of August 1567, when he established the Council of Blood, at the head of which stood his confidant, Juan de Vargas. This tribunal condemned, without discrimination, all those whose opinions were suspected and whose riches excited their avarice. The present and absent, the living and the dead, were subjected

to trial, and their property confiscated. The cruelty of Alva was increased by the defeat of his lieutenant, the Duke of Aremberg, and he caused the Counts of Egmont and Hoorn to be executed. He afterward defeated the Count of Nassau on the plains of Gemmingen. Soon after, the Prince of Orange advanced with a powerful army, but was forced to withdraw to Germany. The Duke stained his reputation as a general by new cruelties, his executioners shedding more blood than his soldiers. The pope presented him with a consecrated hat and sword, a distinction previously conferred only on princes. Holland and Zealand, however, still resisted his arms. A fleet fitted out at his command was annihilated, and he was everywhere met with insuperable courage. This, and perhaps the fear of losing the favor of the king, induced him to request his recall. Philip willingly granted it, as he perceived that the resistance of the Netherlands was rendered more obstinate by these cruelties, and was desirous of trying milder measures. In December 1573 Alva proclaimed an amnesty, resigned the command of the troops to Louis de Requesens, and left the land in which he had executed 18,000 men, as he himself boasted, and kindled a war that burned for 68 years, cost Spain $800,000,000, its finest troops, and seven of its richest provinces in the Low Countries. Alva led an army into Portugal, gained two battles in three weeks, drove out Don Antonio, and reduced all Portugal, in 1581, to subjection to his sovereign. He made himself master of the treasures of the capital and permitted his soldiers to plunder the suburbs and surrounding country with their usual rapacity and cruelty. It is said of him that during 60 years of warfare he never lost a battle and was never taken by surprise.

Alvarado, Pedro de, a Spanish soldier of fortune, the companion and lieutenant of Cortez: b. Badajoz about 1499; d. 1541. He was of good family, his father being a knight of the order of St. James. In 1518 he accompanied Grijalva in a small expedition sent by Velasquez, governor of Cuba, to explore the American coast. A considerable amount of the precious metals was obtained by barter, and Alvarado was despatched to Cuba with this treasure and with a report of the regions which had been explored. When Cortez was called away to meet Narvaez, who had been sent by Velasquez with a superior force to supersede him in command, he left the capital and his royal captive, Montezuma, in Alvarado's charge, and in 1523 was sent with a considerable force to reduce the tribes of Indians in the direction of Guatemala. Having beaten off all opponents he founded a city now called Guatemala la Vieja, and established a port on the Pacific, which he called Puerto de la Posesion. Embarking for Spain, he was received with great honor by the emperor Charles V., who, in acknowledgment of his services, made him governor of Guatemala. He shortly returned to America with a numerous band of knights and kinsmen, and Guatemala speedily became a prosperous city. An attempt which he subsequently made on Quito, but which he was induced to relinquish, was resented by Pizarro as an intrusion within the boundaries of his command, and he embarked a second time for Spain to vindicate his conduct to the emperor.

Alverstone, Sir **Richard Everard Webster,** first baron A.; British Lord Chief Justice; b. 22 Dec. 1842. He was educated at King's College, the Charterhouse Schools, and Trinity College, Cambridge. In 1868 he was called to the bar and became Q. C. ten years after. He was appointed attorney-general in June 1885 in the Conservative Government, and in spite of the fact that he never held the position of solicitor-general and did not at the time occupy a seat in Parliament. He was elected for Launceston in the following month and later exchanged his seat for the Isle of Wight which he continued to represent until his elevation to the House of Lords. Except under the brief Gladstone administration of 1886 and the Gladstone-Rosebery Cabinet of 1892–5. Sir Richard Webster was Attorney-General from 1885 to 1899. In 1893 he represented Great Britain in the Bering Sea arbitration, and five years later he discharged the same function in the matter of the boundary between British Guiana and Venezuela. In 1899 he succeeded Sir Nathaniel Lindley as Master of the Rolls, at the same time being raised to the peerage as Baron Alverstone. In October of the same year he was elevated to the office of Lord Chief Justice upon the death of Lord Russell of Killowen.

Alvey, Richard Henry, American jurist: b. 1826. He was admitted to the bar in 1849; was a member of the Maryland State Constitutional Convention; chief judge of the Fourth Judicial Circuit, and a judge of the Maryland court of appeals in 1867-83; chief-justice of the latter court in 1883-93; became chief-justice of the court of appeals of the District of Columbia in 1893, and one of the Venezuela boundary commissioners in 1896.

Alvord, Benjamin, American soldier: b. Rutland, Vt., 8 Aug. 1813; d. 17 Oct. 1884. Received a military education at West Point, and after serving in the second Seminole war, and in the Mexican war also, was paymaster of the Department of Oregon, 1854-62. He was brigadier-general of volunteers, 1862-65, retiring from the service in 1881 with the rank of brigadier-general. He published 'Tangencies of Circles and of Spheres' (1855); and 'The Interpretation of Imaginary Roots in Questions of Maxima and Minima' (1860).

Alvord, Henry Elijah, American soldier: b. Greenfield, Mass., 11 March 1844. He entered the army in 1862 and had risen to the rank of major in 1865. He was a cavalry captain in the regular army 1866-72, and chief engineer on Gen. Sheridan's staff 1868-69. From 1886 to 1888 he was professor of agriculture in the Massachusetts Agricultural College, and was president of the Maryland Agricultural College 1888-92. He has for many years been prominent as an authority on agricultural questions.

Alwar, a town of Hindustan, capital of state of same name, situated at the base of a rocky range of quartz and slate, 80 m. S.S.W. of Delhi. It is surrounded by a mud wall, of which the gates only are flanked by bastions, and it is very poorly built. The only edifices worth notice are the rajah's palace, which is of a cubical form and has its walls pierced with numerous small windows and decorated with rude and glaring paintings; a pavilion of white marble, built by the late Rao Rajah, near a very deep tank which he had executed, and displaying no small degree

of taste; and several Hindu temples, in a style imitated from Mohammedan structures. A fort, crowning the lofty mountain which overhangs the town, is highly ornamented and serves the rajah both as a summer palace and as an asylum in times of danger. Pop. (1901) 56,750.

Amadis, a name appearing frequently in the chivalric poetry of the Middle Ages. Of the numerous romances that may be grouped under it, that which narrates the adventures of Amadis of Gaul is at once the most ancient and the best. It is believed that the earliest forms of the story were a lost Castilian version, about 1250, and a Portuguese version, also lost, composed about 1370 by Vasco de Lobeira of Porto. Very likely these earlier versions may have been in verse. Instead of these we have a Spanish prose version written by Garcia Ordoñez de Montalvo about 1465, but first printed in 1508. This romance is one of the three spared by the licentiate and the barber at the burning of Don Quixote's books, and the barber's reason is that "it is the best of all the books of this kind."

The Spanish Amadis romances consist of 12 books, of which the first four contain the history of Amadis of Gaul. The earliest existing version of this is, as has been said, that of Montalvo, and the earliest edition now in existence is dated 1508. He himself added a fifth book containing the adventures of Esplandian (1510), the eldest son of Amadis and Gloriana; later writers have multiplied the posterity of the old hero. Already in 1510 appeared a sixth book with the history of Florisando, his nephew; in 1514, 1526, and 1535, respectively, a seventh, eighth, and ninth book, with the wonderful histories of Lisuarte of Greece, a son of Esplandian, and Perion of Gaul, and the still more wonderful history of Amadis of Greece, a great-grandson of the Gallic hero. Then follow Don Florisel of Niquea and Anaxartes, son of Lisuarte, whose history, with that of the children of the latter, fills the tenth and eleventh books. Lastly, the twelfth book, printed in 1546, narrates the exploits of Don Silves de la Selva, son of Amadis of Greece and Finistea. A French translation appeared in 1540, an Italian in 1546, an English in 1588, while a version in German was published in 1583. The French translators increased this series of romances from 12 to 24 books; the German, to 30. Lastly, a Frenchman, Gilbert Saunier Duverdier, at the beginning of the 17th century, arranged all these romances into a harmonious and consecutive series, and with his compilation in seven volumes, the 'Roman des Romans,' brought the history of Amadis and the series of about 50 volumes to a close. A version in French was published by Creuzé de Lesser in 1813; in English, by William Stewart Rose, in 1803.

Amador, Manuel, first president of the Republic of Panama: b. 1841; was for many years minister of France in Panama. He is a soldier, statesman, scholar and diplomat, and was largely instrumental in forming the new Republic of Panama (q.v.).

Amalgam, an alloy in which mercury is an important constituent. Silver and gold amalgams occur in nature to a limited extent, but most of the amalgams are of artificial origin. Four general methods of forming them may be noted. (1) By direct contact of mercury with the metal to be amalgamated. Amalgams of antimony, arsenic, bismuth, cadmium, gold, lead, magnesium, potassium, silver, sodium, tellurium, thorium, tin, and zinc may be obtained in this way. The different elements mentioned combine with the mercury with varying manifestations of affinity, the amalgamation of sodium being attended with the production of heat and light, while in the case of zinc it is often necessary to bring the zinc and mercury together in the presence of dilute acid before they will combine evenly and smoothly. (2) By immersing the metal to be amalgamated in a solution of a salt of mercury. Copper, gold, platinum, and silver can be amalgamated in this way. (3) By reversing the process last described, and bringing mercury in contact with a salt of the metal whose amalgam is desired. The mercury, in certain cases, will partially replace the metal in solution, the portion so replaced combining with the mercury with the production of the desired amalgam. A valuable modification of this method consists in substituting for the metallic mercury an amalgam of zinc or of sodium, the zinc or sodium changing places with the metal in solution. Amalgams of bismuth, calcium, chromium, iridium, iron, magnesium, manganese, osmium, palladium, and strontium may be prepared by the use of sodium amalgam. (4) By electrolysis, the metal whose amalgam is desired being used as the cathode in a solution of a mercurial salt. (The cathode may also be metallic mercury, and the electrolyte a salt of the metal whose amalgam is desired.) This process is in commercial use for the production of sodium hydrate, a solution of sodium chloride (common salt) being electrolyzed with a mercury cathode. The cathode absorbs the sodium with the formation of sodium amalgam, which is subsequently decomposed by contact with water. In practice the process is continuous, a part of the mercury cathode being exposed to the electrolytic bath, while another part is simultaneously exposed to the action of the water.

In the formation of amalgams there is usually but little thermal effect. In the case of sodium and potassium, however, a very considerable amount of heat is evolved; and in the formation of amalgams of bismuth, lead, and tin, heat is absorbed.

There is considerable evidence in favor of the view that many amalgams contain definite compounds of mercury and the other constituent metals. Thus when certain amalgams are heated (say) to the boiling point of sulphur, the excess of mercury present appears to be volatilized, so as to leave a body behind that has a definite chemical composition. In this way Sonza obtained amalgams having the apparent composition Au_8Hg, $Ag_{13}Hg$, $Cu_{10}Hg$, Na_3Hg, and K_2Hg, the last-mentioned being silvery in appearance and crystalline in structure. But it is said that all these amalgams, as well as many others, continue to lose mercury slowly when the temperature is maintained high; and this fact, while not disproving the existence of a definite compound of mercury and the metal, lessens its probability. Amalgams having the composition $CuHg$, $AgHg$, $FeHg$, Zn_2Hg, Pb_2Hg, and $PtHg_2$ have also been prepared by expelling the excess of mercury from amalgams richer in that metal by exposure to a pressure of 70 tons to the square inch.

One of the most interesting amalgams from the standpoint of chemical theory is the amalgam of the hypothetical radical "ammonium," which is described under AMMONIA.

The affinity of mercury for gold is put to practical use, in mining, for the recovery of small particles of gold from auriferous gravel or crushed quartz. The details of the process vary somewhat according to the nature of the material from which the gold is to be extracted; but in general it may be said that the pulverized gold-bearing quartz or gravel is washed, in a finely divided state, over a plate of amalgamated copper, to which the gold particles adhere. From time to time the gold amalgam is scraped from the copper plate, and more mercury is added. The presence of sulphur (from pyrites) seriously interferes with this process, by causing the formation of a sulphid of mercury which destroys the efficiency of the amalgamated plate. The mercury is then said, in miners' parlance, to become "sick." To prevent this, the ore, if originally rich in pyrites, is roasted to expel the sulphur before being submitted to amalgamation. See GOLD.

Mirrors are silvered by amalgams. One of the simplest of those so used is composed of 1 part of tin to 3 of mercury. A superior amalgam for this purpose contains 2 parts of bismuth, one part each of lead and tin, and 4 parts of mercury. In dentistry the "silver filling" used for closing the cavities in teeth is an amalgam. Its composition varies somewhat, but a preparation containing 2 parts of mercury and 1 part of pulverized zinc gives excellent results. It hardens quickly, and expands slightly in solidifying, thus filling the cavity tightly. Amalgams of copper, silver, lead, and tin have a volume smaller than the sum of the volumes of their constituents. See BATTERY.

Amana, Iowa, a town in Iowa co., 28 m. W. of Iowa City, the site of a German communistic religious colony founded in 1885. It includes the seven villages of Amana, the oldest and largest; East Amana; Middle Amana; High Amana; West Amana; South Amana; and Homestead. The society is governed by a president and a board of 13 directors, and each village is controlled by seven or more elders appointed by the board of directors. Family life is kept up, but in every village are from four to sixteen "kitchen-houses" where meals are prepared and served. The community owns and operates woolen, flour, and saw mills, dye shops, machine shops, and other industrial establishments, and agriculture is extensively followed. The inhabitants dress plainly and in sober colors. The community is primarily a religious organization, and the sect itself dates its founding from Eberhard Gruber, in Würtemberg, in 1714. By its members it is known as "The Community of True Inspiration." Pop. (1901) 1,767.

Amanita, a genus of fungi nearly related to the genus *Agaricus*, to which the common mushroom belongs, and for which two of its poisonous members (see below) are sometimes mistakenly eaten. *A. muscaria*, the fly mushroom, so called from its use as a decoction in milk for killing flies, is commonest in the birch, beech, and pine woods of Europe and America. It has a variously colored cap — white, yellow, orange, red, etc.— usually warted above and sometimes four or more inches in diameter; white or occasionally yellow gills; and a long white stem with bulbous base. Though universally considered poisonous it is said to be used by certain Old World peoples to produce a kind of intoxication. *A. phalloides*, death-cup, deadly agaric, deadly amanita, is commonly found in woods, especially in damp weather, from early summer until mid-autumn. It is usually white, sometimes light yellow or grayish; its cap is seldom as large as four inches in diameter; its gills white; its stem hollow and slender above, solid and bulbous at the base, which is surrounded by a cup which has suggested one of its common names. *A. verna*, a supposed variety of *A. phalloides*, which it greatly resembles, appears in spring and summer. With reasonable caution on the part of the collector none of these species should be mistaken for the common mushroom, because all three grow singly in woods and have white gills and white spores; whereas the mushroom grows in clumps in pastures and upon lawns, occasionally in grassy open woods. Its gills are pink in young specimens and darker in old ones; its spores dark-colored and it has no cup at the base of the stem.

Aman'itin, a strongly basic ptomaine (or perhaps leucomaine) occurring in the poisonous fungus *Amanita muscaria* (*Agaricus muscarius*), or fly agaric. Amanitin is not poisonous, but is converted by oxidation into muscarin (q.v.), to which the deadly effects of the fly agaric are due. Amanitin is believed to be identical with cholin, neurin, and sincalin. See NEURINE.

Amapa'la, a seaport of Honduras on the north shore of the island of Tigre, in the bay of Fonseca. It has an excellent harbor and carries on an important exporting trade. It was founded in 1838. Pop. 1,100.

Amaranthus, the typical genus of herbaceous plants of the natural order *Amaranthaceæ*. This order consists of apetalous plants chiefly inhabiting tropical countries, and remarkable for the white or reddish scales of which their flowers are composed. These preserve their appearance after they are plucked and dried, and on this account poets make the plant an emblem of immortality. The name is from the Greek, meaning "not withering," and was originally *Amarantus*. The natural order contains about 500 species, some of which, as love-lies-bleeding, prince's feather, and cockscomb, are common garden plants. In the wild state they are mostly troublesome and unsightly weeds, of which the tumbleweed (*A. albus*) and pigweed are well-known American examples. Some of the foreign plants are cultivated as pot herbs, and others for their medicinal properties. Their chief commercial value is as decorative plants, for which purpose immense quantities are used in the southern parts of Europe, where they are employed to ornament the churches when fresh-grown blooms are not procurable. Plants of this order are almost entirely annuals.

Amarna Letters, a collection of several hundred cuneiform clay tablets discovered in 1887 at Tel-el-Amarna, a village on the Nile in Middle Egypt, on the site of a city built by Amenophis IV. They comprise the correspondence of the Egyptian court about 1400 B.C., and with but three exceptions are in the Babylonian language. Some of them were written by

Amenophis III. and Amenophis IV., and other royal personages contemporary with these, but the majority are by Egyptian officials and allies in Syria. Their discovery has thrown much light not only on the history of Egypt itself, but upon the condition of the Holy Land prior to the Hebrew invasion. An English translation of the letters, by Metcalfe, with the title 'The Tel-el-Amarna Letters,' appeared in 1896.

Amaryllidaceæ, or **Amaryllideæ,** a natural order of monocotyledonous plants, generally bulbous, sometimes fibrous-rooted, occasionally with a tall, cylindrical, woody stem. Their characteristics are a highly-colored flower, six stamens, and an inferior three-celled ovary. They are natives chiefly of the Cape of Good Hope; but species are found in the warmer parts of Europe, in every part of America and tropical Asia, and a few species in Australia. To this order belong the snowdrop, the snowflake, the daffodil, the belladonna-lily, the so-called Guernsey lily (probably a native of Japan), the Brunsvigias, the bloodflowers (Hæmanthus) of the Cape of Good Hope, different species of Narcissus, Amaryllis, Galanthus, Crinum, Agave (American aloe), Atamasco lily, star-grass, spider lily, etc.; many of the family are very poisonous. The agave and sisal (q.v.) are of considerable commercial value, but the order as a whole is chiefly ornamental.

Amaryllis, the name of a shepherdess in the Theocritean 'Idyls' and the Virgilian 'Eclogues'; also of a character in Spenser's 'Colin Clout's Come Home Again'; of the shepherdess in love with Perigot, in Fletcher's pastoral 'The Faithful Shepherdess'; and of a character in Buckingham's comedy 'The Rehearsal.'

Amasa (more correctly **Ammishai),** the nephew of David, king of Israel. He was commander-in-chief of Absalom's rebel army, and after its defeat received from David a promise of the same post in his own army in place of Joab. On the renewal of the revolt under Sheba, Amasa was assigned the task of collecting the men of Judah; as he did not appear when due (perhaps knowing too much about the disturbance), Abishai was sent in his place, and Joab's company took part without commission. Amasa met them at Gibeon, and under pretense of a salute Joab stabbed his cousin and rival (2 Sam. xx. 9).

Ama'sia, a city in Asiatic Turkey, province of Anatolia, 335 m. E. of Constantinople, famed as the ancient capital of Pontus and as the birthplace of the historian Strabo. It is built almost entirely of stone and contains a massive citadel and a notably fine mosque. Silk is made here, and salt, wine, wheat, and cotton are also exported. Pop. about 30,000.

Ama'sis I., an Egyptian king, the first monarch of the 18th dynasty. His rule lasted for some 20 years following 1600 B.C. He expelled the Shepherd Kings from Egypt and laid Palestine and Phœnicia under tribute.

Amasis II., an Egyptian king: b. 570; d. 526 B.C. He cultivated friendly relations with the Greeks, and established Greek commerce at Naucratis. Pythagoras and Solon are said to have visited him. He greatly enriched Memphis.

Amateur. Up to the middle of the 19th century this now ever-recurring word was used exclusively to define those who for the love of the arts, and not for the profit to be derived from the exercise of them, painted, or engraved, or sang. In such of the recreations and sports as were then in vogue, and which some men engaged in for pleasure and others for pay, the phrase used to distinguish the two classes varied. If a man of means rode a horse in a race or a steeplechase for the pure love of equestrianism, while others rode for fees, the one was called a "gentleman rider," and the rest were "jockeys." So again in cricket, those who participated in matches were designated by two titles: "gentlemen," denoting those who participated *con amore*, and "players," those who played for pay. It was always easy to recognize one from the other, for in the list of published names one class was always designated "Mr.," as "Mr. Somerville," while the "players" would lack that prefix and appear as "Thomas Sadler."

Golf of that period was more democratic; neither the word amateur nor any other distinguishment had appeared; cobbler and prince played together, and for stakes too, without a thought of one or the other losing caste. James II., king of England, while still Duke of York, chose an Edinburgh shoemaker as his golfing partner to play two Scotch peers for a goodly stake of money which he and the cobbler won. The prince did the honorable thing by giving up his half of the stake to the shoemaker, with which and his own share the latter bought a house in the Cripplegate of the city.

Football at that period was largely in abeyance, except among schoolboys, and the need of definitions had not arisen.

The word amateur in sports first appears in connection with rowing. Up to the year 1835 such rowing contests as had taken place had been on the one hand confined to watermen, who at that time had to serve apprenticeships and could not ply their trade without: and on the other hand to inter-collegiate and inter-university crews. Neither class needed definitions. But at that time an open regatta was organized at Henley, in which it would have been manifestly unjust to allow watermen and others who had had a lifetime's experience and of hardened training to enter and compete against those for whom the regatta was really intended, that is, those who loved aquatic sport for its own sake and followed it only as a recreation at seasonable times. Hence rules were formulated and have ever since been in operation which distinguished the professional from the amateur and precluded the possibility of the one contesting against the other. So strong is this feeling still in rowing at Henley that in 1902 a further restriction was made against the entry of any crew that had within a month from its entry been trained by a professional.

When track athletics, about 1850, first crystalized by the impulse given it by colleges and clubs, similar conditions existed. The only representative of this form of recreation at that time was the old and hardened trotter-around-the-track, sometimes for the gate money derived from it, sometimes for the benefit of the betting men. Ostensibly it would have been unfair to handicap young collegians by

permitting their intermingling, even if for ethical reasons it had not been desirable. Rules were here again formulated which had the effect of barring the professional and defining the amateur. The rule of the Amateur Athletic Association of Great Britain may be quoted as expressing the then prevalent feeling:

"An amateur is one who has never competed for a money prize or staked bet, or with or against a professional for any prize, or who has never taught, pursued or assisted in the practice of athletic exercises as a means of earning a livelihood."

Football added another temptation on account of its possibilities in city centres of attracting large numbers and much gate money. Here, too, the barrier was raised, in both the association and the Rugby games, along lines which America has followed. But the United States authorities in all recreations have gone a great deal farther in the strictness of their definition of the word amateur, and in safeguarding against persons who receive any portion of their traveling or hotel expenses: a notable example of this occurred in 1902, when the National Golf Association precluded from the amateur ranks any player who participated in the generosity of railroad companies or hotel proprietors.

It would seem an easy thing, from the foregoing facts, to be able to formulate a phrase which should generically and yet accurately describe an amateur, but it is not, as the story of the endless definitions adopted and abandoned, or amended, though made by experts, attests.

The spirit is the old spirit "for the love of the art or game and not for personal gain"; even if a present literal definition were attempted, it might be rendered obsolete by new legislation in a short time. Those who are purposing to enter any particular recreative contest in which the status of the amateur is material must consult the last rules of the organization governing it.

Ama'ti, an Italian family of Cremona, celebrated for their skill in making violins. ANDREA AMATI (b. about 1520; d. 1570) was the earliest member to follow the art, but few of his instruments remain. His younger brother, NICOLA, made basses. Andrea's sons, ANTONIO (b. about 1555) and GERONIMO (b. 1556; d. 1630), worked after their father's manner, but Geronimo's son NICOLO (b. 3 Dec. 1596; d. 12 Aug. 1684) excelled all others of his family, and in his hands the art of the Cremonese school reached its perfection. His most famous pupils were Antonio Stradivarius and Guarnari. The line ended with his son GERONIMO, whose violins were of inferior quality.

Amatitlan, or **Amatitan**, a Central American town in the republic of Guatemala, 20 m. S.W. of Guatemala City. The houses are low and built of mud. There are hot springs in its vicinity and salt and alum wells also. The occupation of the people consists chiefly in the production of cochineal. Pop. about 8,600.

Amaurosis, a disease of the retina or its nervous connections, resulting in partial or complete blindness. It usually begins with confused vision; there may then be the appearance of a black spot in the centre of an object looked at, and graded dimness of sight develops. See AMBLYOPIA.

Amau'ry I., a king of Jerusalem: b. 1135; d. 11 July 1173. He was the son of Baldwin II., and reigned from 1168 to 1173, in succession to his brother, Baldwin III.

Amau'ry II., sometimes known as **Amau'ry de Lusignan**, titular king of Jerusalem: b. 1144; d. at Acre, 1205. He was king of Cyprus 1194–1205, succeeding his better known brother, Guy de Lusignan.

Amaxichi, or **Leokas**, a Greek town, the capital of Santa Maura, or Leucadia, one of the Ionian Islands. A Greek archbishop resides here. It is on the E. coast of the island and possesses a small harbor. Pop. 6,000.

Amazi'ah, king of Judah about 797–779 B.C.; son of Joash. He punished his father's murderers and reconquered the Edomites; but according to 2 Kings xiv. was so puffed up by his victory over these Bedouin that he challenged Joash, king of Israel, an incomparably more powerful, civilized foe, to a war. Joash retorted with stinging contempt, wishing to avoid the contest, but Amaziah insisted, and Joash routed his army and captured him, stormed and sacked Jerusalem, destroyed a part of the wall, and carried away to his capital of Samaria hostages, and a large amount of spoil, including gold and silver treasure and temple utensils. Amaziah, after his release and 15 years further of reign, was killed by conspirators at Lachish (2 Kings xiv. 19).

Am'azon, a river of South America, once called the Orellana after its Spanish explorer. Its source is found in the Peruvian Andes, its headwaters, the Marañon and Ucayale rivers, uniting in about lon. 74° W. From lon. 70° its course is wholly in Brazil, and its entire course from the source of the Ucayale to its mouth is about 4,000 miles, its width increasing from over a mile at the Peruvian frontier to 150 miles. The Amazon receives the waters of about 200 tributaries, 100 of which are navigable, and 17 of them 1,000 to 2,300 miles in length. From the north it receives the Santiago, Morona, Pastaza, Tigre, Napo, Putumayo, Japura, Rio Negro (a branch of which, the Cassiquiare, strangely enough connects it with the Orinoco), Uatama, Trombetas, etc.: from the south the Huallaga, Ucayale, Yavari, Jutahy, Jurua, Teffé, Coary, Purus, Madeira, Tapajos, Xingu, etc. The depth varies much. From the sea to the mouth of the Rio Negro, about 750 miles in a straight line, the depth is nowhere less than 30 fathoms; higher up it varies from 10 to 12, and up to the junction of the Ucayale there is depth sufficient for the largest vessels. The rapidity of the stream is considerable, especially during the rainy season (January to June), when it is subject to great floods, being on the average 2¾ miles per hour; in some places it is 4, or even more, and in others as low as 1 mile. The river is perceptibly affected by the tides up as far as the town of Obidos, 400 miles from its mouth. The phenomenon of the *bore*, or as it is called on the Amazon the *pororoca*, occurs at the mouth of the river at spring tides on a grand scale. The waters of the ocean rush into the river in the form of huge waves 10 to 15 feet in perpendicular height, three or

four of which follow each other with irresistible force. The waters of the Amazon swarm with alligators, turtles, and a great variety of fish, of which Agassiz in 1866–7 discovered 1,163 species. The country through which it flows is covered with immense and impenetrable forests, affording homes for a vast variety of animals, including birds of the most gorgeous plumage. The area drained by the Amazon and its tributaries is estimated at 3,000,000 square miles. This region produces an immense variety of vegetable substances, including a great many drugs, dyewoods, and valuable timber trees. The products it might be made to yield by cultivation are almost innumerable, among the chief being cotton, sugar, indigo, coffee, cocoa, and tobacco. The Amazonian water system affords some 16,000 miles of river suitable for navigation. Steamers began to ply on the river in 1853, and latterly the navigation was opened up to all nations. Pará is the chief seat of the trade on the river, and Manáos, situated about 1,000 miles up, is also a place of active trade. About 40 river, coasting, and ocean steamers now ply regularly between Pará and Manáos every month, a number of them being British. The mouth of the Amazon was discovered by Yañez Pinzon in 1500, but the stream was not navigated by any European till 1540, when Francis Orellana descended it. The river has been explored in later times by La Condamine (1743-4), Humboldt (1799), Prince Adalbert of Prussia (1842), Herndon (1850), Avé Lallemant (1858), Bates (1861), Marcoy (1866), Agassiz (1866-7), and others; and its tributaries by Hartte, Chandless, Abendroth, etc. See Herndon, 'Exploration of the Valley of the Amazon' (1853); Bates, 'The Naturalist on the River Amazons' (1864); Wallace, 'Narrative of Travels on the Amazon and Rio Negro' (1870; second edition, 1889); Matthews, 'Up the Amazon and Madeira Rivers' (1879); Guillaume, 'Amazon Provinces of Peru' (1888); Schutz-Holzhausen, 'Der Amazonas' (1895). See SOUTH AMERICA.

Amazo'nas, or **Alto Amazona**, the largest of all the Brazilian States and the farthest north: bounded N. by Dutch and British Guiana and Venezuela; E. by the State of Pará; S. by Bolivia and the State of Matto Grosso; W. by Colombia, Ecuador and Peru. Its area is 732,-460 sq. m., or nearly three and a half times that of France, and except for mountain ranges on the Venezuelan border it is an alluvial plain. Its capital is Manaos. Population of the State (1900) 207,600. (See Temple, 'The State of Amazonas.') The name Amazonas is also borne by a territory of Venezuela with a population of about 20,000, and a department of Peru with a population of about 35,000.

Am'azons, in Greek legends a nation of female warriors. They were fabled to have cut off their right breasts in order not to interfere with their use of the bow, and variously to have expelled men from their country or kept them in subjection for the continuance of the race. The earliest traditions locate them in Asia Minor, and relate their appearance at the siege of Troy under their queen Penthesilea.

Amazonstone, a beautiful green or blue feldspar. It is a variety of the mineral microcline and occurs in magnificent crystals in granite near Pike's Peak, Col. Inferior crystals occur in New Jersey, the Ural Mountains and many other localities. Large quantities of green, cleavable amazonstone have been obtained at Amelia, Va., and have been worked up as semi-precious and decorative stones.

Ambala, or **Umballa**, the name of a district of N. India and its capital. The latter was the scene of a treaty between the governor-general of India, Lord Mayo, and the Emir Shere Ali of Afghanistan in 1869. The town contains several important churches, a dispensary, hospital, and a leper asylum. Pop. 80,000.

Ambale'nia, Colombia, a city in the department of Tolima, on the Magdalena River, 50 m. W. of Bogota. It is the trade centre of a rich agricultural region, exporting large quantities of excellent tobacco. Pop. 8,500.

Ambari Hemp. See HIBISCUS.

Ambarv'alia, a Roman festival in honor of Ceres, which was observed in May. The blessing of the goddess was then besought on the wished-for harvest.

Ambassador (from the Mediæval Latin *Ambasciator*, an agent), a diplomatic officer of the highest rank, the representative of one nation at the court of another. In this capacity he is expected to support the interests and dignity of his own State. Ambassadors are ordinary when they reside permanently at a foreign court, or extraordinary when sent on a special occasion. When ambassadors-extraordinary are vested with full powers, as of concluding peace, making treaties and the like, they are called plenipotentiaries. Ambassadors are often loosely styled ministers. Envoys are ministers employed on special occasions, and are of less dignity than ambassadors. Until 1893 the United States had been represented at foreign courts by persons with the rank of ministers-resident, accredited in the care of the great powers as envoys-extraordinary and ministers-plenipotentiary. In that year, however, an act of Congress was passed allowing the President to accredit ambassadors as United States representatives at several of the more important European courts. When acknowledged as such, ambassadors are exempted absolutely from all allegiance and from all responsibility to the laws of the country to which accredited. Should they be so regardless of their duty, however, and of the object of their privilege, as to insult or openly to attack the laws of the government, their functions may be suspended by a refusal to treat with them, or application can be made to their own sovereign for their recall; or they may be dismissed and required to depart within a reasonable time. An ambassador is considered as if he were out of the territory of the foreign power, by fiction of law, and it is an implied agreement among nations that the ambassador, while he resides in the foreign state, shall be considered as a member of his own country, and the government has exclusive cognizance of his conduct and control of his person. Ambassadors' children born abroad are held not to be aliens. (7 Coke, 18 *a.*) The persons of ambassadors and their domestic servants are exempt from arrest on civil process. (3 Burr. 401, 1731.)

Amba'to, a town of Ecuador, on the slope of Chimborazo, 70 m. S. of Quito. It has a flourishing trade in grain, sugar, and cochineal. Pop. 12,000.

Amber, one of the most important and valuable of the fossil resins. It is one of the oxygenated hydrocarbons and its mineralogical name, succinite, emphasizes one of its distinguishing characteristics, namely, the presence of from 5 to 8 per cent of succinic acid. Its composition is represented by the formula $C_{40}H_{64}O_4$. It occurs in irregular masses, usually of small size but sometimes weighing up to 15 or 18 pounds. It has a yellow color, resinous lustre and conchoidal fracture. Its hardness is 2 to 2.5 and specific gravity 1.05 to 1.1. Along the shores of the Baltic Sea, especially in East Prussia, mining for amber has been carried on for two centuries. In this region shafts are sunk through a superficial stratum of marl and sand, a bed of lignite with light sands and gray clays, and finally a layer of green-sand, 50 to 60 feet thick.

All of these strata contain amber, but in the lower portion of the green-sand there is a stratum 4 to 5 feet thick of «blue earth» in which amber nodules occur so abundantly that 50 or 60 square rods yield several thousand pounds. This «blue earth» stratum extends out under the sea and there the amber is freed and cast upon the shores by the waves, especially after the autumnal storms. Numerous other localities are known, but none are so prolific. In the United States amber-like resins have been found in the green-sand formation of Martha's Vineyard, Harrisonville, N. J., and elsewhere.

Pliny declared amber to be «an exudation from trees of the pine family,» a conjecture that proves to be correct. The fact that it was at one time fluid or nearly so is established by its occasional inclusion of insects; and its antiquity is also established by the fact that most of the species of insects so included are now extinct.

Amber becomes strongly electrified when rubbed, and the power that it then possesses, of attracting light bodies to itself, was probably considered by the ancients to be the outward sign of the mysterious virtues that they attributed to the mineral. It was greatly esteemed for ornaments and charms, and Pliny says that among women «it had been so highly valued as an object of luxury that a very diminutive human effigy, made of amber, had been known to sell at a higher price than living men, even in stout and vigorous health.» He also says that a necklace of amber beads was considered to protect the wearer from secret poisons, and to be efficacious as a counter-charm against sorceries and witchcraft. In the time of Nero an expedition sent from Rome to the Prussian amber-beds returned with 13,000 pounds of the precious substance.

In modern times amber is chiefly used for the manufacture of mouthpieces for tobacco pipes and for the preparation of a kind of varnish. The attractive power exhibited by amber when rubbed was the first electrical phenomenon observed by man, and the word «electricity» was derived from *electrum*, the Greek name for amber.

Amber-fish, any one of a genus of fishes (*Seriola*) related to the pilot-fishes, many species of which are found along our coasts, the most of which are known by other names. The great amber-fish, or amber-jack, is a food-fish of some importance in the Gulf of Mexico and the West Indies, reaching a weight of 100 pounds. Others in that region are more commonly known as madregals; and a species of the Pacific Coast is the highly-prized yellow-tail (q.v.). The name refers to the prevailing color.

Am'berg, the ancient Bavarian capital of the upper Palatinate, is situated on both sides of the Vils, in the midst of numerous iron-works. It is well built, and on the site of its former walls are shaded walks. Glass, iron wares, stoneware, tobacco, beer, vinegar, and arms of good quality are manufactured here. The principal buildings are a Gothic church of the 15th century, the royal palace, the town-house, and the Old Jesuits' College, and it possesses a gymnasium and a large library. At Amberg the Archduke Charles defeated the French general, Jourdan, on 24 Aug. 1796. Pop. (1900) 22,000.

Amber Gods, The, a story by Harriet Prescott Spofford, published 1863. It is characterized by superb depth and richness of color, like a painting by Titian. An amber amulet or rosary possessing mysterious influences gives the title to the story.

Am'bergris, a gum-like substance of great value in the making of perfumes, obtained from the intestinal canal of the sperm whale, or found floating in pieces of various sizes on the surface of the sea. It is a product of cetacean digestion, and often contains the beaks of cuttle-fish, a fact which conclusively proves the place of its origin, until recently much in doubt. When first extracted from the alimentary canal it has the feeling and consistency of thick grease, and chemically seems to be of the nature of cholesterin, but after exposure to the air hardens and acquires its characteristic sweet earthy odor. Some odd stories were told by the old writers to account for its origin, of which the least absurd was that it was the excrement of the whale. It was held by the ancients to be of great value in certain diseases, but is now used entirely in connection with perfumery, and is worth about $20 a pound. The name is also given to a barren island on the coast of Yucatan, on account of the quantities of ambergris gathered along its shores.

Amber Insects. The great majority of the fossil insects of the Oligocene (Tertiary) period have been obtained from the amber of the Baltic shores of Prussia, upon which they had rested in life, stuck fast and then been overflowed. The most fragile and delicate flies, moths, and many other insects, besides spiders, mites, centipedes and crustacea, are preserved in this gum or resin, which was evidently formed in the same manner as gum copal, also a late tertiary or quaternary gum.

Ambitious Woman, An, a novel by Edgar Fawcett (1883). It is a keen yet sympathetic analysis of an American female type whose dominant trait is social ambition. Claire Twining is reared in the ugly poverty of a Brooklyn suburb, but is clever and capable, with strong aspirations for the luxuries of life. Through the good offices of a schoolmate she gains a social foothold. If Claire's transformation seems a little sudden, there is genuine strength in the story and much truthful observation of city life in New York.

Ambler, James Markham Marshall, surgeon and Arctic explorer: b. Virginia, 30 Dec. 1848; d. in the Lena Delta, Siberia, 31 Oct. 1881. Educated at Washington and Lee University and the Medical College of the University of Maryland, he practiced medicine in Baltimore 1870–4; entered the navy as assistant surgeon 1874; and was selected as volunteer for that post to the Jeannette arctic expedition under George W. De Long, 1879. When their vessel sank, 13 June 1881, he accompanied his chief along the Lena and was alive at the date of the last entry in De Long's journal, 30 Oct. 1881, but probably died the following day. His remains were discovered by Chief Engineer Melville 23 March 1882. Upon his body were found memoranda on 'Ice Formed by Sea Water,' and 'Remarks on Snow Crystals,' published in De Long's 'Journal' (Boston 1883).

Ambleside, a town in the English lake district, Westmoreland, the home of Harriet Martineau, and near which Wordsworth and Dr. Arnold resided. The chief industry is the manufacture of coarse woolen goods. Pop. (1901) 2,536.

Ambleteuse, a French village on the English Channel 6 miles north of Boulogne, noted as the landing-place of James II. on his flight from England 1689. In 1805 Napoleon erected a monument here to the Grand Army. Pop. (1901) 685.

Amblydactyla. See AMBLYPODA.

Amblygonite, am-blig'ō-nīt (from the Greek *amblygonios*, "obtuse-angled"), a mineral crystallizing in the triclinic system, and having the chemical formula $AlPO_4.LiF$. The lithium is often partially replaced by sodium, and the fluorin by hydroxyl (OH). Its hardness is 6, and its specific gravity about 3.05. It is translucent and white, or more or less tinged with various colors. It occurs in certain localities in Saxony, Norway, France, and Peru; and in the United States it has been found in Maine and Connecticut. It is a valuable lithia ore.

Amblyopia, defective, weak, or blunted vision, a word now widely employed instead of the term amaurosis, meaning blindness (q.v.), since the modern methods of examination of the retina have made known the more exact character of the affections of this part of the eye. Defective, weak, or blunted vision due to disorder of the retina usually may be attributed to the following main causes: (1) certain poisons, notably alcohol, wood alcohol in particular, tobacco, lead, and uræmic poisoning of Bright's disease; (2) certain functional or reflex disturbances, as in hysteria; (3) changes in and about the optic nerve, as pressure of inflammations, or of tumors, leading to optic neuritis; (4) cerebral changes, such as hemorrhages, tumor of the brain, localized injury of the brain, usually leading to localized types of amblyopia (hemianopsia); (5) defective cerebral development, causing congenital amblyopia.

Amblyop'sidæ, a family of fresh-water fishes closely allied to the cyprinodonts and remarkable for living altogether in caves, except one species found in the ditches of the rice-fields of South Carolina. Among many peculiarities may be noted the facts that the vent is at the throat instead of in the usual position behind the ventral fin, and that all of the underground species are blind. See CAVE-DWELLING ANIMALS.

Amblypo'da, an extinct order of hoofed mammals found in the Eocene formations of North America and Europe. They are distinguished by a primitive pattern of teeth and short post-like feet resembling those of elephants. The chief types are Pantolambda, Coryphodon and Uintatherium (qq.v.).

Amblys'toma, a genus representing a subfamily (*Amblystomatinæ*) of salamanders of North and Central America, and northern Asia. The parasphenoid bone is toothless. A common American species is the spotted salamander (*A. tigrinum*) whose young in certain Mexican lakes never reach the adult condition, and are known as "axolotls." See AXOLOTL; SALAMANDER.

Am'bo, a reading-desk or pulpit, which in early churches was placed in the choir. The epistle and gospel were read from the ambo, and sermons sometimes preached from it. It had two ascents — one from the east and the other from the west. In many churches there were two ambos, one on each side of the choir, from one of which the gospel was read, and from the other the epistle. The earliest are at Ravenna in the cathedral and the Church of Saint Apollinare, and are of carved marble. (See PULPIT.) The name ambo was also given to an eagle-shaped reading-desk, now usually termed a lectern.

Amboise, am'bwäz, **Aimeric d',** a famous French admiral, brother of Georges d'Amboise (q.v.); d. 1512. He became in 1503 Grand Master of the Knights of St. John in Rhodes, and gained a great victory over the Sultan of Egypt in 1510.

Amboise, Bussi d'. See BUSSI.

Amboise, Georges d', a French cardinal and minister of state: b. at Chaumont-sur-Loire 1460; d. 1510. He became successively bishop of Montauban, and archbishop of Narbonne and of Rouen, and in 1498 Louis XII. made him prime minister. He failed in his attempt to secure the papacy, but his policy toward France was wise and statesmanlike. He reformed the Church, remitted the people's burdens, and conscientiously labored to promote the public happiness.

Amboise, a French town in the department of Indre-et-Loire, on the Loire, 15 miles by rail east of Tours. It lies in a rich vineyard district and has been called "the Garden of France." The town is memorable as the scene of the conspiracy of the Huguenots against the Guises (1560). It contains a beautiful chateau dating from the time of the Renaissance. Pop. (1901) 4,600.

Amboy'na, or **Amboina,** the most important of the Molucca Islands, being the seat of their government and the centre of the commerce in nutmegs and cloves; greatest length, 33 miles; greatest breadth, 10 miles; area, about 260 square miles. It is composed of two unequal peninsulas united by an isthmus about a mile broad, the larger known as Hitu, the smaller as Leitimor. Its general aspect is attractive and its climate salubrious. It is covered almost throughout with forests, affording

a great variety of beautiful wood for inlaying and ornamental work. Sugar and coffee are cultivated. The surface is generally rugged and hilly, sometimes rising into mountains of granite. The soil in the valleys and along the shores is very fertile, but a large portion remains uncultivated. In 1605 Amboyna was taken by the Dutch from the Portuguese, and shortly afterward some English factories were erected there; but in 1623 the Dutch seized the English fort, tortured frightfully Capt. Towerson and nine others to obtain a confession of conspiracy, and put them to death — a performance famous as "The Massacre of Amboyna." Pop. 30,000. Amboyna is also the name of one of the residencies into which the Molucca Islands are divided, including Buru, Caram, Aru Islands, the Bandas, and others. Pop. 95,000.

Amboyna, the capital of the Dutch residency of that name situated on the northwest shore of the peninsula of Leitimor and defended by Fort Victoria. The houses, built in Dutch fashion, are generally of one story, owing to the frequency of earthquakes, one of great severity occurring in January 1898. It contains a governor's palace, town-house, two Protestant churches, several mosques, an orphan hospital, a theatre, and a large covered market-place. The streets are wide, and are planted on each side with rows of fruit-trees. Pop. about 10,000.

Ambriz, äm-brēj', a seaport, capital of a district of the same name in the Portuguese colony of Angola, west Africa. Originally the capital of Quibanza it was taken by the Portuguese, who in 1855 built a fort, a custom-house, and a church which formed the nucleus of the present town. It has a number of factories and a trade in india-rubber, coffee, and palm oil. Pop. about 3,000.

Ambros, äm'brōs, **August Wilhelm,** a notable Austrian writer on music: b. 17 Nov. 1816 in Mauth, Bohemia; d. Vienna 28 June 1876. He was trained for the civil service and served in it with distinction; but his tastes led him elsewhere, and he rose to eminence as the author of 'The Limits of Music and Poetry,' besides numerous essays and studies connected with art. His masterpiece, 'The History of Music' (1862–8) a work which cost him many years of labor, was carried only to the fourth volume. A fifth, completing the work, was added by Langhaus.

Ambrose, Saint, a celebrated Latin father of the Church: b. 333, or according to other accounts, 334, probably at Treves (the ancient Augusta Trevirorum), where his father resided as pretorian prefect of Gallia Narbonensis; d. Milan, 4 April 397. It is told that a swarm of bees covered the eyes of the boy while slumbering in the court of his father's castle, and the nurse was astonished to perceive the bees going in and out of his mouth without doing him any injury. His father, possibly recalling a similar wonder, mentioned of Plato, prophesied future greatness for his son. Ambrose studied law at Rome under Anicius Probus and Symmachus, and then went to Milan and began to plead causes while yet a youth. His pleadings were so eloquent and skilful that in a short time Probus, the prefect of Italy, chose him a member of his council; and in 369, with the approval of the Emperor Valentinian, appointed him governor of the provinces of Liguria and Æmilia (North Italy). In 374 he was called to the bishopric of Milan by the unanimous voices of Arians and Catholics. Ambrose long refused to accept this dignity, but in vain. He fled by night, and thought himself on the way to Pavia, but unexpectedly found himself again before the gates of Milan. At length he yielded, received baptism, for he had hitherto been only a catechumen, and eight days after was consecrated a priest. The 7th of December is still celebrated by the Church on this account. On his elevation to the bishopric he bestowed all his wealth on the Church and among the poor, resolving to live as simply as possible, and at the same time to exercise his functions as an ecclesiastical ruler with firmness and vigor. He was employed by the court to negotiate with Maximus, then threatening Italy, whose advance he succeeded for a time in arresting (383). Four years later he was sent on a like mission, but his conduct on this occasion so offended Maximus that he had to return to Milan, having accomplished nothing. In his struggles against the Arian heresy he was opposed by Justina, mother of Valentinian II., and for a time by the young emperor himself, together with the courtiers and the Gothic troops. Backed by the people of Milan, however, he felt strong enough to deny the Arians the use of a single church in the city, although Justina, in her son's name, demanded that two should be given up. He was commanded to quit the city, but this he refused to do, being still supported by the people. About this time Ambrose, instructed by a dream, searched for and found the relics of two martyrs, Gervasius and Protasius. The people crowded to see these bones, and, according to Ambrose himself, the eyes of the blind were opened and devils were cast out by touching them. Although the court derided these miracles they were accepted by the people, and the triumph of orthodoxy was secured. He had also to oppose paganism. In 390, after the massacre at Thessalonica, he refused the Emperor Theodosius entrance into the church of Milan for a period of eight months, only restoring him after a public penance. (See THEODOSIUS.) The later years of his life were devoted to the more immediate care of his see. His writings (the best edition is by the Benedictines, two vols. folio, 1686–90), bear marks of haste, and show his theological knowledge to have extended little beyond an acquaintance with the works of the Greek fathers, from whom, especially Origen, he borrowed considerably. The "Ambrosian Chant" or "Te Deum Laudamus" has been ascribed to him, but was written a century later. He may be considered the father of the hymnology of the Latin Church. He is the patron saint of Milan, which observed his 15th centenary in 1897.

Ambro'sia, in the Greek mythology, a balsamic juice which formed the food of the gods and preserved their immortality. It was used also as an ointment. Mortals permitted to partake of ambrosia received an increase of beauty, strength, and swiftness, becoming in some measure assimilated to the gods.

Ambrosia Beetle. See WOOD-BORING BEETLES.

Ambrosian Chant. See GREGORIAN CHANT.

Ambrosian Library, public library in Milan; founded by the Cardinal Archbishop Federigo Borromeo, a relation of St. Charles Borromeo, and opened in 1609. It now contains over 175,000 printed books and 8,400 MSS.

Amelan'chier, a genus of shrubs or small trees of the natural order *Rosaceæ,* natives of Europe, Asia, and America. The species, which are few in number and closely related, have alternate, simple, deciduous leaves, numerous racemes of white showy flowers appearing in early spring often before the leaves, and, in summer, edible spherical or oblong red or dark purple berries with more or less bloom. They are ornamental, hardy, succeed upon many soils and in many climates, and are readily propagated by seeds or suckers.

Amélie-les-Bains. See ARLES.

Amendment, in law, the correction of any mistake discovered in a writ or process. At common law, amendments, in the absence of any statutory provision on the subject, are in all cases in the discretion of the court for the furtherance of justice. The power of amendment is regarded as incidental to the exercise of all judicial power. Amendments are very liberally allowed in all formal and most substantial matters under statutes in modern practice. They are allowed either without costs to the party amending, or upon such terms or conditions as the court may see proper to impose.

In legislative proceedings, a clause, sentence, or paragraph proposed to be substituted for another, or to be inserted in a bill before Congress, and which, if carried, actually becomes part of the bill itself. As a rule amendments do not overthrow the principle of a bill. The Senate of the United States may amend money-bills passed by the House of Representatives, but cannot originate such bills. The Constitution of the United States contains a provision for its amendment. (U. S. Const. Art. 5).

America: a brief account of the derivation and meaning of the word. The name Amalric (in Old High German Amalrich or Amelrich; Gothic Amala-reiks or -reikis; variants Am-el, Am-ul, and Am-il-rih, -rich, or ric) originated among the Goths in Northern and Central Europe; was adopted by other nations of the Teutonic stock before the great migration of those kindred peoples; and was carried into all West European countries — even to England and the Mediterranean coasts — by the Northern conquerors between the fifth and twelfth centuries. The famous East Gothic dynasty of the *Amala* received its name, according to tradition, from a national hero whose mighty labors had earned for him the title *Amal,* which, as we shall presently explain, was a purely democratic term, connoting personal character and achievement, without the slightest implication of social rank.

From the dynastic name, the Goths as a race, or, more narrowly, the East Goths, were familiarly called *Die Amelungen;* the Amal king in the fourth century ruled from the Baltic to the Black Sea; at the beginning of the sixth century a king of the West Goths in Spain and France, a grandson of Theodorich the Great, was called *Amalarich.* The word of democratic meaning thus spread through a few lands was destined to live, in the centuries that followed, united inseparably with the other short word which appears in the name of the West-Gothic king.

The signification of the compound is of extraordinary interest. Its second member appears in Old English (for example, in the Anglo-Saxon epic of Beówulf) as *ric,* meaning *powerful,* or, when a substantive, *control, domain,* or *empire* — the modern German *Reich.* According to von Humboldt ('Examen Critique,' vol. iv) and Professor von der Hagen, the fundamental meaning of the first member (its root, *am,* often occurring in the dialects of Iceland and Scandinavia in the forms *ama, ambl,* etc.) is *labor,* endurance of great toil. Accepting this view, we find that the title of the Gothic national hero, *Amal,* expressed popular appreciation of "the man of great or laborious enterprises." Simply that. In order to show that *Amal,* when uniting with the aristocratic monosyllable, retained its original value, so characteristic of the people who used it every day; that, at least, they never thought it meant "the mighty," as some authorities have asserted recently; we need only point to the facts that they prefixed it to *ric,* which itself signified "mighty," and that folk stories served to remind them constantly of the primitive meaning of the first member. Amalric, then, was the name which compacted the old ideal of heroism and leadership common to all Germanic tribes, the ideal that stands out most clearly in the character of Beówulf — the Amal of Sweden, Denmark, and Saxon England. The compound plainly meant what the North European hero-stories described: The man who ruled because he labored for the benefit of all.

In France, this name was softened to *Amaury.* Thus, a certain theologian who was born in the 12th century at Bène, near Chartres, is called indifferently Amalric of Bène or Amaury of Chartres. England, in the 13th century, could show no more commanding figure than Simon of Montfort-*l'Amaury,* Earl of Leicester, to whom King Henry once said, "If I fear the thunder, I fear you, Sir Earl, more than all the thunder in the world." A Norman *Amalric* was that Earl Simon, creator of a new force, and a democratic one, too, in English politics. "It was," says the historian Green, "the writ issued by Earl Simon that first summoned the merchant and trader to sit beside the knight of the shire, the baron, and the bishop in the parliament of the realm." In Italy, after the Gothic invasion, the Northern name suffered comparatively slight euphonic changes, which can be easily traced. As borne by a bishop of Como in 865 it became *Amelrico* or Amelrigo. But the juxtaposition of the two consonants *l* and *r* presented a difficulty in pronunciation which the Italians avoided: they changed *lr,* first, to double *r,* and then to a single *r.* Still, 600 years after Bishop Amelrigo died, the Florentine merchant, explorer, and author usually retained the double *r* in his own signature, writing "*Amerrigo* Vespucci," and, by the way, accenting his Gothic name on the penultimate (Amerígo, not Amérigo). In Spain the name must have been rare, since it was often used alone to designate the Florentine during his residence in that country. There was, ap-

parently, no other Amerigo or Amerrigo in the Spanish public service early in the 16th century. We must again look toward the North for the scene of the next important change, and among the men of a Northern race for its author.

Martin Waldseemüller, a young German geographer at St. Dié, in the Vosgian Mountains, whose imagination had been stirred by reading Amerigo's account of voyages to the new world, bestowed the name *America* upon the continental regions brought to light by the Florentine. It is not enough to say, with Mr. John Boyd Thacher ('Columbus,' vol. 3; compare also his interesting 'Continent of America'), that Waldseemüller «suggested» this designation. As editor of the Latin work, the 'Cosmographiæ Introductio' (5 May, 1507), he stated most distinctly, with emphatic reiteration, his reasons for this name-giving; placed conspicuously in the margin the perfect geographical name, America, and at the end of the volume put Vespucci's narrative. Further, on a large map of the world, separately published, he drew that fourth part of the earth which was the 'Introductio's' novel feature — marking it firmly, «America.» It is impossible to adopt the suggestion of Prof. von der Hagan, that Waldseemüller was distinctly conscious of giving the new continent a name of Germanic origin. «Quia Americus invenit,» says the 'Introductio,' «Americi terra sive America nuncupare licet.» But the case stands otherwise when we ask why Europeans generally caught up the word. Its association with so many men before Vespucci certainly commended it to Northern taste.

MARRION WILCOX,
Author of 'History of War with Spain,' etc.

America, the second in size of the isolated land masses of the globe; containing about three tenths of the total land surface and perhaps half the cultivable area, but less than one tenth the population. The name was originally used only for central Brazil, and was fairly enough applied in honor of the Italian, Amerigo Vespucci (q.v.), who discovered it. It was first employed for the entire known Western world by Mercator in 1541, and is usually but not properly understood to include Greenland, which is physically a part of Europe.

The extreme points marking the limits of this vast continent are: N., the point of Boothia Felix, in the Strait of Bellot, lat. 71° 55′ N., lon. 94° 34′ W.; (in Alaska, Point Barrow, lat. 71° 23′ 31″ N., lon. 156° 21′ 40″ W.) S., Cape Froward, lat. 53° 53′ 45″ S., lon. 71° 18′ 30″ W., or, if the archipelago of Tierra del Fuego is included, Cape Horn, lat. 55° 59′ S., lon. 67° 16′ W.; W., Cape Prince of Wales, lat. 65° 33′ N., lon. 167° 59′ W.; and E., the Point de Guia, lat. 7° 26′ S., lon. 34° 47′ W. Its total area is not far from 16,000,000 sq. m., without Greenland or the polar archipelago (which comprise perhaps 1,000,000 more), of which North America with Central America and the West Indies contains some 8,700,000 and South America 7,300,000. There can be no pretense of exactness about these figures, however: Alaska and polar Canada are not thoroughly surveyed, and good recent authorities differ by 250,000 miles or more even as to accessible lands like South America. The total population is over 150,000,000.

Nominally one «continent,» it is really two if not three sections, geologically independent in origin. The northern, from the Arctic Ocean to the Isthmus of Tehuantepec in Mexico on the west (where the last slopes of the Anahuac plateau of the Rocky Mountains sink to the plain, and the Guatemalan highlands are not in sight) and Florida on the east, is connected with the southern by two great parallel ridges. One of these, called Central America, is continuous, joining South America at the west side, and dwindling to 28 miles across at the Isthmus of Panama; the other submerged, consisting of Haiti, Porto Rico, and the Lesser Antilles, joining at the eastern side; the two united transversely by Cuba and Jamaica and the projection of Yucatan, and enclosing the Caribbean Sea, 1,500 miles from end to end. The continental mass, 8,700 miles from Alaska on the northwest and Boothia Felix on the northeast to the south end of Patagonia, is prolonged by a vast archipelago of arctic islands up from Hudson Bay, ending suddenly like a drift line about 125° W. lon., and at Grant Land about 83° N. lat., and by another at the south called Tierra del Fuego, on the Antarctic Ocean, to a total of some 9,600, nearly four fifths the distance from pole to pole. But as with the eastern continent, some force has massed the land chiefly at the north: two thirds of the continent is north of the equator; the extreme point of the continuous northern islands reaches to a few hundred miles from the pole, the last of the southern is 2,350 miles from it; Alaska is 1,100 from the north pole, Argentina is 3,400 from the south. The same causes make it form part of a nearly solid ring on the Arctic Ocean, the northwest projection of Alaska being separated from the northeast of Kamchatka by only 40 miles of strait, and the continent being connected with Europe by a series of islands one to two hundred miles apart, while the immense though widely unequal gulfs of the Pacific west and the Atlantic east separate the habitable portions.

The axial dimensions of the continent are not very dissimilar to those of the eastern. Its length is about the same as the breadth of the other from China to England, its greatest breadth about the depth of the other from the Arctic to the Indian Ocean; but its relative slenderness gives it less than half the area. It is in fact an immense peninsula slightly severed from the main mass, with the shape and the southerly direction of the majority of peninsulas. From nine to ten thousand miles long, it is little over 3,000 across its main north and south lines, from Labrador to British Columbia, or from Peru to Brazil; about 2,100 from Savannah to San Diego, a few hundred across Mexico, 1,725 at the Tropic of Capricorn just above Rio Janeiro, 750 from Buenos Ayres to Valparaiso, and so on southward. Moreover, as shown by its configuration relatively to that of the opposite shores of the eastern, and the differences of the northern and southern continents, it is a strip rent from the eastern mass by a tremendous geological convulsion, the Atlantic being the channel thus left. That ocean is relatively small and of regular breadth from Labrador and Brazil to England and Liberia, compared with the immense abyss of the Pacific and its sweeping arch from the Bering Sea to Australia and Chile; from Newfoundland to

Ireland is but 1,900 miles, from Cape St. Roque in Brazil to Cape Palmas in Liberia but 1,700; while from San Francisco to Yokohama is 5,500, from Quito to Singapore (almost exact antipodes) 12,500, and from Valparaiso to Sydney 8,000. But a still more striking proof is that the continents fit together almost as accurately as the blocks of a dissected map, allowance being made for the long period since their separation. The great eastern projection of North America is toward the Bay of Biscay, that of South America toward the Gulf of Guinea, the great western projection of Africa toward the Gulf of Mexico and the Caribbean Sea. The same closure (about 45°) which would bring Newfoundland against Brittany, and Labrador against the British Isles, would make the Congo empty against the Brazilian coast and the West Indies surround Senegambia. In physical character also the northern and southern portions of each are akin: northeastern North America has the broken island-fringed peninsular coasts and the gigantic inlets and inland seas of Europe, while South America has the solid coast-wall and the absence of lakes characteristic of western Africa. Not to mention the great polar archipelago or Hudson's Bay, and allowing the archipelago at the south end of Chili to set off against the Alexander Archipelago along the south Alaskan coast, there is no parallel in South America to oceanic bodies like the Gulf of Mexico, or lesser ones like the Gulf of St. Lawrence northeast to Puget Sound northwest, or the Gulf of California southwest; or the mass of sheltered bays and sounds along the eastern coast to the Great Lakes; to islands like those around the mouth of the St. Lawrence or to Vancouver's, or peninsulas like Nova Scotia, Florida, and Lower California. It must be said, however, that the rent between the eastern and western continental bodies must have taken place very early, for there are strong physical differences between South America and Africa: the chief mountain ranges of the former being on the west, of the latter on the east; the African rivers are less copious, and mostly have cataracts above their mouths.

Apart from this, the structural characteristics of the northern and southern continents have striking similarities, largely nullified for human use by the difference in location already mentioned. Each is a rather slender triangle with the vertex to the south. Each is joined to the next northern portion of the globe by a northwestern peninsula, the trend of the whole as far south as Bolivia being regularly southeast from Bering Strait, just as that of the Asiatic coast to the Philippines is southwest; so that the north Pacific is a semicircular gulf. Each has to the north an immense archipelago and a vast island-ringed inland sea. Each has a framework of mountain and plain correspondent in general, though with some important differences. In each, according to the law that the largest continental mountain chain is on the side of the largest ocean, there is a western range of immense height and mass, hundreds of miles broad and split into parallel sections sometimes connected by transverse spurs, stretching its entire length; quite recent in origin, and the volcanic action which raised it still energetic in parts. The Andes in South America thus correspond to the Rockies in North America; but the current idea that they form part of one continuous system is erroneous,— the Andes end in Venezuela, and the Rockies are of different genesis. Each continent has on the east a much shorter chain, much older and therefore much lower, from the erosion through geologic ages, and its volcanic fires long since spent; and as the highest points are worn down earliest, each is now rather a broad plateau with some elevations than a mountain wall. The Alleghany-Appalachian system in the United States corresponds to the Brazilian chain, which has no one distinctive title. Each continent has also a lateral range beginning in the north centre, turning first south and then east till it ends somewhat north of the eastern vertical chain, and cut in its course by the chief river running northeastward; and in each it is much the oldest part of the continent. The Laurentian chain in North America, crossed by the Saskatchewan, is a trivial counterpart to the great lateral ranges of Venezuela and the Guianas, crossed by the mightier Orinoco.

In each continent the two main ranges are connected by an almost uninterrupted plain many hundreds of miles broad, sloping southward to the ocean, and drained by three immense hydrographic systems with slight and sometimes non-existent divides: one running east and emptying just north of the eastern vertical range, the Great Lakes and the St. Lawrence in the north corresponding in position to the oceanic Amazon in the south; the second running south and discharging a little south of the same range, which thus forms one side of a huge triangle of which the rivers form the other two,— the Mississippi and Missouri in North America comparable to the Parana and Paraguay which form the La Plata in South America; a third running northeast and discharging into the northern ocean, the Saskatchewan, with the Red River of the North and Lakes Winnepeg and Manitoba, corresponding to the Orinoco. Besides these, each has a river following the eastern side of a spur from the main range up to the northern ocean, the Mackenzie in the arctic regions and the Magdalena in Colombia, though the former is the drainage of a great arctic plain while the latter is confined between two ridges. With regard to the watersheds, those of North America lie within a few miles of each other in Minnesota; the headwaters of the Illinois in the Mississippi basin lie within a half mile of the Chicago in the St. Lawrence system, and the two have now been connected; the Amazon and Plata systems are only three miles apart; and those of the Amazon and Orinoco are actually connected by the so-called "river" Cassiquiare, a deep and broad natural channel about 150 miles long, running either way according to circumstances.

These, however, by no means exhaust the large drainage systems of North America, though in South America the closeness of the western chain to the ocean throws the whole burden on the east. The Pacific slope of the north is drained in the semi-arctic regions by the immense Yukon, one of the great rivers of the globe. On the eastern side the great mass of the arctic moors sends its drainage through a network of small streams, and sinks like Great Bear, Great Slave, and Athabasca

Lakes, by the Mackenzie to the northern ocean, the Great Fish River taking the east arctic waters. Farther south the Pacific drainage is by the Fraser into Puget Sound, and by the Columbia into the Pacific. The smaller Sacramento drains central California. The Great Basin between two arms of the Rockies sends its scanty and precarious rainfall into the Gulf of California by the Colorado. East of the range in the south the Rio Grande has a long course and forms the boundary between the United States and Mexico, but, despite its impressive name, is not of great volume. Between this and the Mississippi system several considerable streams drain the Texas region; the Colorado, Brazos, Sabine, etc. East of the Appalachian system a number of fair-sized and beautiful rivers flow to the Atlantic — the St. John's, Penobscot, and Kennebec, the Connecticut, Hudson, Delaware, and Susquehanna, the Potomac, James, Cape Fear, Savannah, etc. In South America the large rivers of the eastern slope are the San Francisco and the Paranahiba of northern Brazil; but between this range and the Amazon system a great plain is drained by the huge Tocantins, which, though emptying only at the mouth of the Amazon, is really a part of its basin.

The drainage systems of America have no parallel on the globe. The Amazon discharges more water into the sea than the eight largest rivers of Asia together, and the Mississippi more than all the streams of Europe large and small. The navigable waters of the St. Lawrence, Mississippi, Amazon, Orinoco, and Plata systems together amount to over 100,000 miles in length. The five Great Lakes of America alone, excluding large bodies like Winnipeg, Manitoba, Champlain, etc., and the polar lakes, make up an area of 89,000 square miles, or considerably more than England and Scotland together.

Another physical similarity between the two continents might be found in the relations of the Gulf of Mexico to the northern continent and the great Argentine plain to the southern: both lie in the same position with regard to the eastern and western mountain chains, though the one is submerged.

But the differences are also great. The main drainage system of the central plain in North America is to the south, by the Mississippi; that in South America is to the east, by the Amazon; while the Great Lakes are scarcely a drainage system at all for anything but the melting snows of the Rockies, which supply them through deep rock fissures. They are hollows in the oldest rock elevation of the continent, with the ground sloping away from them in every direction not far from their shores; not a single considerable stream flows into them, nor even into the St. Lawrence west of Montreal. But the most vital difference structurally is due to the position of the western chain. In North America the chief height is on the eastern flank a thousand miles from the Pacific, the gradually lessening slopes leaving space for an empire along that ocean, and their drainage forming great rivers. In the southern continent it hugs the ocean so closely that not a stream of any size flows into the sea, and the cultivable area is but a petty strip on the coast. More than half the whole western side of South America is occupied by one state, some 1,500 miles long by 50 or 60 wide, which even so finds none too much territory with its slender width and partly barren soil. The northern continent has also an immense advantage in the character of its coast line: what with its archipelagoes, sounds, and river-mouths in the north, and the sheltered indentations farther south, it is well fitted for commerce, while the whole South American coast has only one or two good harbors above Patagonia. The greatest differences in the civilized destiny of the two continents, however, are due to the northward massing of the land heretofore mentioned. All the United States and southern Canada lie in the temperate regions: the largest and most fertile part of South America lies in the tropics. The narrow southern part of North America lies in the warm semi-tropic ocean; that of South America in the south-polar sea. A quarter of all North America is a worthless polar waste, but perhaps as large a space of South America is an uninhabited and pestilential tropic jungle; and the improvements in food production and means of warmth which push back the reign of the one are perhaps balanced by the hygienic inventions and commercial uses tending to reclaim the other. Certainly the northern part has much more arable land and much less miasmatic or enervating climate than the other, nothing whatever that compares with the pestilential coasts and inland swamps of the southern. The Mississippi valley, the largest continuous body of agricultural land on the earth, is not only of immensely greater value than the grassy steppes of the temperate southern plain of South America, but the prairies of the north, which correspond in position to the Amazonian forests in the south, are a still more striking contrast. Commercially the north is equally favored in comparison. From the nearness of the continent to Europe relatively to Asia, and from the structure of the continent throwing the mass of population and production east of the great mountain chain, the chief commercial relations of America must always be with the western side of the other continent. But North America is directly opposite Europe, the commercial head of the world; while South America's eastern neighbor is barbaric Africa, and most of its harbors are either along the miasmatic northern and northeastern coast, unfit for great cities, or the semi-polar shores of Patagonia.

(For general works on American geography and topography see the 'New Universal Geography,' translated by Keane and Ravenstein from Elisée Réclus' French work, 1890–4; Dawson's 'North America, Canada, and Newfoundland,' 1897; Keane's 'Central and South America,' 1901; Shaler's 'Nature and Man in America,' 1891; Wright's 'Ice Age in North America,' 1889; Powell's 'Physiographic Regions of the United States,' in 'National Geographic Monographs,' Vol. I. 1895.)

Physical and Climatic Conditions.— In a continent practically spanning the entire space from pole to pole, every variety of climate may be inferred; and with every elevation from sea-line to everlasting ice even in the tropics, each latitude is sure to contain as endless varieties in itself. In both North America and Asia the western side is both warmer and of more even temperature than the eastern, owing to ocean

currents generated in the tropics and flowing eastward, the Gulf Stream through the Atlantic, the Kuro Shiwo through the Pacific. The Rockies, however, give a peculiar character to western North America, to be mentioned later, and even in interior Alaska the isotherms rise, — the parallel of Dawson City in the Klondike is that of the north end of Hudson Bay and far into south Greenland. The eastern side of both continents has about the same climatic belts: China corresponds fairly to the United States, and Peking has a climate not unlike Boston. But if we compare eastern North America with Europe, and to a less extent South America with the East, the leading trait is its greater cold in every zone from just below Great Bear Lake; St. Petersburg and Christiania are on a level with the southern tip of Greenland. Sitka has much the same parallel as Aberdeen; Copenhagen and Moscow, Glasgow and Edinburgh, correspond with central Labrador, northern James Bay, and some distance north of Lake Winnipeg. All the British Isles, all the Netherlands, and the greater part of Germany, are north of the city of Winnipeg, which itself is about on the parallel of Paris; St. Paul and Ottawa correspond to Bordeaux, Turin, and Bucharest, centres of wine and roses; Boston and Chicago to Rome, New York to Naples; Philadelphia is south of Madrid and Constantinople; Washington corresponds to Lisbon and Corfu, St. Louis to Athens. The thirtieth parallel is about that of New Orleans and the Isthmus of Suez; the twentieth passes through the heart of Mexico, also just below Calcutta and Mecca, and through the Sudan and Sahara; the tenth through Venezuela, also through Guinea and just above Ceylon. The equator touches Quito and the mouth of the Amazon, and also divides Sumatra and Borneo and Lake Victoria Nyanza; the Amazon and the Kongo traversing about the same zones. Even allowing for the elevation of the Mexican plateau, the temperatures of India and of the deserts of Arabia and Africa cannot be paralleled even on our tropical coasts. The difference is due to environing conditions and internal structure combined. Above the European mass is a partially thawed sea; above that limit in America lie many hundred miles of ice-clad land masses, while to the northeast is the continental mass of ice-capped Greenland, piercing deep into the eastern side the polar inlet of Hudson Bay. But a partial cause is the mountain framework which in Europe lies mainly east and west and in America north and south. In the latter, therefore, what is practically one long plain stretches from the Arctic Ocean to the Gulf of Mexico, the polar winds finding no obstruction as they sweep southward. There is not a spot in North America east of the Rockies absolutely secure from intense frosts; and there are no definite north-and-south climatic belts, the only sharp divisions being those east and west of the Rockies. In Europe and west Asia, on the contrary, where the mountains cut off the polar winds, the climate will often vary from north-temperate to semi-tropic within a score of miles. This isolation of different parts, giving the most varied lives and habits time to grow into deep-set racial distinctions, has produced by their varied strains and interaction the splendid civilization of the Western world; while the two great plains which fill the centre of each continent, linked by a fertile and temperate plateau, in itself the most tempting of all, gave no opportunity for differentiation, and the undiversified monotony of a single racial stock and culture was one of the influences which kept progress at a spot reached by European races thousands of years before.

Geology.— The great western chain of both continents, which would seem to be the chief formative base of both, is in fact very much the newest section in each case, though each is of independent origin as shown by the energy of still remaining volcanic action in both, while the uplift of the eastern side has so long ceased that erosion has worn them down many thousands of feet, trenching immense valleys, and building up vast plains to the west by their detritus.

The Archæan portion of North America, the first in order of appearance above the water, is the northeastern part: the elevation in which the Great Lakes and Hudson Bay are hollows, the Laurentian system of Canada, the Adirondacks of northern New York, and a southern tongue east of the Blue Ridge. The line of forces thenceforth acted steadily to the westward, the surface formations regularly growing more recent in that direction. This portion is not merely the oldest of the western continent, but one of the oldest on the globe, the "New World" being new only from the standpoint of European history, not of geology or ethnology. This and the polar archipelagos are composed of Azoic or Palæozoic rocks of extreme antiquity. The mountain escarpment skirting Labrador and extending north and west is mainly granite and other archaic rocks. To the west stretches the vast pre-Silurian plateau called by Suess the "Canadian buckler." By erosion this has been almost denuded of its upper Palæozoic strata, and the whole of Hudson Bay excavated to a slight depth on the surface of its eastern section. The eastern part of the Appalachian system is mostly Silurian; its western plateau and the bases of most of the Mississippi valley are Carboniferous; while as we go westward we encounter in succession Triassic, Cretaceous, and Tertiary formations.

The Rocky Mountain system shows the greatest activity of volcanic forces at its ends, in Alaska and Mexico. In the old portions of the United States and Canada there are no active volcanoes; and the strength of eruptive force, greatest in the Aleutian Islands, steadily diminishes eastward and southward, occasional eruptions occurring on the southwestern coast, while Mount Wrangell is semi-eruptive only. In Mexico, Popocatapetl and others indicate the beginning of the equatorial belt of volcanic forces exhibited in Central America and the Antilles. But all the Cordilleran system is relatively of recent elevation, though old enough for heavy erosions to have taken place, exposing strata of every age as they were tilted up, creating some valleys and filling up others. In the region from California to Puget Sound the surface over many thousand square miles is lava, the valley of the Snake and Columbia for long distances being cut through lava beds, and fields of black scoriæ forming a peculiar feature in the northern Pacific States and Pacific Canada. To the south of the Appalachian system, along

the Atlantic and the Gulf, the flooring is Cretaceous and Tertiary, therefore of recent uplift.

In South America the eastern highlands are also of enormous antiquity, as shown by their archaic composition, with a sandstone cap not since submerged, their horizontal layers, deep erosions, and detritus plains, indicating no uplift since the earliest times and a great height of the original chain. The Andes (q.v.) are quite recent, and full of volcanoes still or but recently active, but they are not all of a single age, however, and show successive uplifts. The plains between have Tertiary bases under their alluvial surface.

Much of the erosive action on these primitive elevations and the uplifts between them has been due to a vast glacial ice cap, the so-called Laurentian glacier, which at an uncertain but relatively recent period, ending probably from 50,000 to 100,000 years ago, covered all North America from the polar regions down to Philadelphia and the Ohio and as far west as the Missouri, leveling hills and hollows, creating soils, excavating lake beds, changing the courses of streams and the outlets of gigantic lakes, cutting out and blocking up fiords and harbors, and depositing enormous masses of rock and gravel moraines. To this, among other things, is due the creation of New York harbor and Niagara Falls, and the turning of the Great Lakes through the rocky St. Lawrence valley instead of the Mohawk and Hudson. This ice cap has by no means wholly disappeared yet: the immense glaciers on the northwest coast and in the Rocky Mountain heights, some of them hundreds of square miles in extent, are remnants of the one great glacier of ancient times which still covers entirely the turtle-back conformation of Greenland. South America too has had its glacial periods, spreading from the south-polar regions and producing the same effects as in its northern neighbor. The great height of the Andes keeps them still existent up to and beyond the equator, and on the south they are of frequent occurrence.

The Cordilleran System.— The two great axial chains which form the western base of the double continent, though (as said) of independent origin, have strong similarities and a like relation to the remainder of the surface, and may conveniently be treated together. For their detailed composition and characteristics, see ANDES and ROCKY MOUNTAINS. It should be noted that these are not mere dividing walls, but vast formative elements of the continental masses, and themselves of continental volume. With their foothills and spurs they amount in South America to at least 1,000,000 square miles in area, and in North America to some 2,500,000, or toward a third of the entire surface. They include almost every possible character of soil and climate and natural product, and suitability for every employment,— agriculture, manufactures, or mining. They make climates of their own, so that no inference can be drawn from that on one side to that on the other, and the two may have the difference of five degrees of latitude or five thousand miles of distance: one side may be a sponge, the other a rainless desert, one a glacier, the other a garden. They make the difference between Puget Sound and Labrador, and on the other hand between the Mexican plateau and the Nicaraguan plains, between Peru and Carácas. They enclose fertile provinces and deserts of rock and sand each large enough for an empire, and have great lakes and considerable rivers entirely their own.

As the development is better studied from the south, we shall begin with South America, whose cordilleras descend by steep short terraces to the seashore, or to a narrow belt of level land immediately adjoining it, form regular chains, display the loftiest masses of all America, and send out only short branches to the eastern plains; whereas the North American cordilleras lean, in the west, on elevated plateaus, so as to favor a large development of rivers, are less vertical in their structure and less high, and send to the east more extensive ramifications. The names of particular groups of the Andes are taken from the countries to which they more especially appertain; thus, proceeding from south to north, we have the cordilleras of Chile, Bolivia, Peru, Ecuador, and Colombia. This is the highest mountain mass on the globe, and except the Himalayas has the highest peaks. Beginning among the rock islands of the Fuegian archipelago, it runs through Patagonia as a low single range with summits of perhaps 8,000 feet; rises swiftly through Chili, growing at once higher and more multiplied, with summits of 12,000 to 18,000 feet, till it culminates in the stupendous *nevado* of Aconcagua, from 23,000 to 24,000 feet high, the loftiest elevation on the western hemisphere. Beyond this it divides into two enormous parallel arms with a high plateau between, and lower ranges to the east in Argentina increasing its complexity. Thence to the Isthmus it is not a ridge, but a rock continent 200 or 300 miles wide, with a great number of peaks from 19,000 to 21,000 and even 22,000 feet high, and the very «passes» over them 15,000 or 16,000 feet above the sea, terrific and nearly impassable gorges above the highest summits in Europe. Sometimes it contains three or four parallel ranges, with two and even three immense tillable valleys on the same base. It attains its greatest breadth at about lat. 18° S., in central Bolivia, where it is some 300 miles wide, with three main ranges; and at this point, in the northern part of the province of Tacna, taken by Peru from Bolivia, it and the correspondent coast curve northwest as far as 5°, its course in this direction being exactly coincident with the limits of Peru. On these plateaus was situated the empire of the Incas. Just northeast of the turn it holds the great Lake Titicaca, some 1,800 miles in area, on a high plateau 12,645 feet above the sea. This part is called the Royal Cordillera, and contains several peaks above 20,000 feet, Ancohuma (21,490) being the highest. At the Gulf of Guayaquil it again turns north, with a gradual trend east to about lat. 4 N., when it curves north and west to meet the Isthmus, forming a large but nameless gulf. Near the equator, in Ecuador, are a number of very lofty volcanic summits, the two highest and most famous of which are Chimborazo, 20,498 feet, and Cotopaxi, 19,613 feet. Thence to the Caribbean the height decreases, and in Colombia it divides into three, two running north and the third extending well into Venezuela, the true end of the Andean system.

Central America is hardly a part of either great system. The Isthmus is a low plateau, succeeded by highlands rather than mountains in Costa Rica; then comes the depression nearly filled by Lake Nicaragua, the largest inland body of water south of the Great Lakes, where the elevation sinks to less than 100 feet above the sea. The mountains begin in northern Nicaragua and occupy the entire breadth of Honduras, Guatemala, and Salvador, from ocean to ocean, but they are not of great height and consist of several detached ranges with active or extinct volcanic peaks. These sink to the broad plain at the Isthmus of Tehuantepec, forming the dividing line between the mass of North American and South American organic species, though zoölogically the central plateau is a northern tongue thrust into two lines of tropic territory along the Gulf and Pacific coast.

The Rocky Mountain system, or northern Cordillera, begins with the plateau of Anahuac on which the City of Mexico is situated, the seat of the original culture overthrown by Cortes. It is from 4,000 to 7,000 feet high, and is flanked by mountain ranges and isolated volcanic peaks, active or quiescent, the highest summits in Mexico. Orizaba, the loftiest, is 18,250 feet high, but the most remarkable and imposing is Popocatapetl, rising 17,520 feet from the floor of the valley, the highest peak of the world in practical isolation, its whole height visible from sea level. At this point the main ridge of the Rockies (the Mexican section is known also as the Sierra Madre, which properly is the name of the northeastern spur) suddenly turns far eastward from the Pacific, and for the remaining 3,500 miles of its course keeps hundreds of miles from it, so that the broad western slope is drained by very large rivers, as the Columbia and Fraser, and in the extreme north the mighty Yukon, one of the great streams of the whole globe. But it throws out lesser arms to the west nearly to the ocean. Between the main range and the great Sierra Nevada arm is enclosed the desert Great Basin of Utah and Nevada and northern Arizona and New Mexico: a waste of alkaline earth and naked rocks, of river courses dry except in the infrequent rains, and roaring torrents then for a few hours or minutes; of the great cañons, gulleys cut sometimes a mile deep into the solid rock by the swift sand-laden currents. It is drained to the Gulf of California by the only real stream of water of any size in the whole region, the Colorado. The Sierra Nevada has for its crowning summit Mount Whitney, in California, 14,898 feet high. Still farther west it throws out the Coast Range, running through California, Oregon, and Washington up to Puget Sound. The Sierra Nevada is continued, through independent volcanic action, by the Cascade Range of Oregon, Washington, and British Columbia, with Mount Shasta, 14,510 feet, in the south, and Mount Rainier or Tacoma, 14,526 feet, in Washington. The system as a whole, across from California and Oregon to Colorado and Wyoming, is 1,000 miles wide, with a number of north-and-south ranges rising from a plateau from 5,000 to 10,000 feet high, and with a large number of peaks between 14,000 and 15,000 feet high. The main range in Colorado has for its chief divisions the Front, Sangre de Cristo, Park, Sawatch, and San Juan ranges; Long's and Pike's Peaks, Blanca Peak, Mounts Lincoln and Harvard, and Uncompahgre Peak are the best known of the summits.

The system follows the coast around nearly to Asia, rising in peaks all along the Aleutian Island, the chief being the noble Shishaldin, 8,000 feet high; and north of Yakutat Bay, a great landmark, where the coast turns west and the greatest glaciers begin, the place where the temperate zone properly gives place to the semi-arctic. A branch continues straight on, runs far north to the Yukon watershed, then turns west again and rejoins the other in southwest Alaska. In the course of the latter it throws up mighty peaks, the monarchs of the northern continent, including Mount St. Elias, 18,024 feet, and Mount Wrangell, a great isolated semi-active volcano, 17,524 feet; the altitude rising as it goes west, it culminates in Mount McKinley, 20,464 feet, the highest elevation in North America.

The Eastern Mountains and the Plains.— In North America the backbone and nucleus of the continent is locally known as the Alleghany system in the northern half of the United States, and the Appalachian in the southern; but for scientific purposes the latter name is commonly extended to the whole. It extends from Gaspé peninsula, between the lower St. Lawrence and Chaleur Bay, below Quebec, through the United States to north Alabama and north Georgia, where the mountains sink down to the great coastal plain which girdles the United States from fifty to a hundred miles back from the coast shore. Between the mountain and plain is a foothill region usually known as the Piedmont region. The mountains are a plateau from 50 to 200 miles wide and averaging 1,500 to 3,000 feet high, but with peaks rising to 6,294 feet in Mount Washington (New Hampshire) and 6,707 feet in Mount Mitchell (North Carolina). The range has many local names for the different divisions, as the White and Green, the Adirondacks, the Taconic, Hoosac, and Catskill, the Alleghany, the Blue Ridge and South Mountain, the Black and Smoky, etc.

On the west they slope through rolling uplands to the most peculiar feature of the North American surface, entirely unlike any other part of the globe, the prairies, called savannahs in English books, but never in American speech: a block of undulating plains of enormous extent in the centre of the Mississippi basin, composed mainly of dark, rich loam from a foot to several feet deep over a bottom of clay, and of such composition that tree-growth is entirely absent naturally and very difficult artificially, even where rainfall is plentiful, though grass and other crops grow abundantly. Often this will be as level as a floor for scores of miles together, and the eye sweeps uninterruptedly over a grassy ocean to the horizon. On the west of this extend to the Rockies lands often as flat as the prairies, but lacking their individual trait and called plains instead. The same features are repeated in northwest Canada from Manitoba to the Rockies.

In South America the eastern chain is similarly formed of several parallel ranges following the Brazilian coast, on a wide plateau, a reduced copy of it running through the Guianas.

The whole centre is an immense plain sloping sharply up to the Andes; but in place of the vast treeless flats of the northern continent there is the most enormous forest of the world, two and a half millions of miles in extent, a swampy jungle inhabited only by a unique tropic fauna and the few savages who wander through its intricate paths. North of this, however, are considerable plains along the Orinoco called llanos. Below the range the country is a great grassy steppe, rather ill-watered and infertile, called pampas, and extending through Argentina and Patagonia.

(See reports, bulletins, and monographs of the United States Geological Survey; reports of the Canada Geological and Natural History Survey; Suess' 'Das Antlitz der Erde' (The Face of the Earth), Prague 1883-8; Felix and Lank, 'Geologie und Paläontologie der Republik Mexico,' Leipsic 1890; Steinmann, 'Sketch of Geology of South America,' in 'American Naturalist,' Vol. XXV., 1891.)

Climate, Rainfall, and Natural Sections.— The habitability of a land outside of arctic regions depends first upon its water supply and secondly upon its disposition. The trade winds which supply the rainfall of all countries by the ocean vapors they carry blow nearly east and west, the easterly called specifically «trades,» the westerly «anti-trades.» The eastern continent has its greatest length in this direction and a great mountain wall on the east; hence much of central Asia lying beyond the reach of vapors remains a permanent desert. America, from its narrowness and its sides being toward these winds, is much more easily supplied. The Great Lakes add to the rainfall in their region; the Gulf of Mexico, as will be demonstrated, turns the whole east centre from a potential desert to a garden: and the only entire deserts are between two arms of the western range in the northern part, and some portion of the strip along the western coast of the southern.

In the polar regions the cold and physical conformation make the water supply of little avail. Northern Alaska and northern Canada are flat, spongy moors but half reclaimed from the ocean, with permanently frozen subsoil, thawing slightly in the brief, intense summer (sometimes of 120°), and developing a few mosses, grasses, and weeds, with dwarfed shrubs and clouds of mosquitoes. (See ALASKA.) But the distance southward to which arctic conditions extend is far greater on the eastern coast than the western, owing to the effect of the Rocky Mountain wall in breaking the force of the polar winds, and of the warm ocean vapors; the latter also make the temperature far more equable. The midwinter arctic temperature of 50° and below has no representative on the western coast. The Labrador coast, latitude for latitude, is 20° colder than the Alaskan in mean annual temperature, about 20° against 40° even in the extreme northwest; and its mean midwinter temperature 30° colder, —25° against 5°. Even from the interior to the western coast the isotherms rise astonishingly: that of north Virginia at lat. 40° N. is that of British Columbia at 50°. On the other hand, the range of temperatures is much greater on the east, the temperature rising pretty steadily as we go southward, to 80° mean annual on the Mexican Gulf coast, a range of 60° from semi-arctic to semi-tropic, while in the corresponding part of southern California it is only 70°, a range of 30°. The midwinter range is over 100° on the east coast, not above 50° on the west; the midsummer is 40° in the east, not over 20° on the whole coast from southern California to Bering Sea. Much greater extremes still are found in the Cordilleran region, where the mean annual embraces a scale of 60°, and the mean midsummer runs from 40° to 95° in southern Arizona and northern Mexico, while the thermometer rises to 120° at times, as at Fort Yuma and similar places.

From about lat. 52° N. to perhaps 44° in the interior and east, the climate, though not quite fatal to civilized energies, is very severe, with winters of seven or eight months, and summers at best but short and not always calculable, though rising to 100° and over in waves; with sudden intense «northers» and «blizzards» of intense cold with fine dry snow sometimes paralyzing business activities for days. The dry atmosphere, however, makes it less trying than the damper though somewhat warmer eastern weather; it has developed great cities and populous States in the United States and flourishing communities in Canada above 50°; and the industrial and intellectual future of the region is as promising as that of any part of the continent. There is not much difference between the central and eastern parts in this respect, Duluth and Quebec, St. Paul, and Ottawa, corresponding closely in parallels and nearly in climate. Northwestern Canada and the northern central States of the United States form the great cattle and wheat district of North America; and this on both sides of the Rockies is the chief timber section. South of this is the great «temperate» section, shading into the semi-tropic by imperceptible degrees, but which in the United States may be roughly divided by the basin of the Ohio. The northern portion has summers and winters of the same general character as the former, but less intense at either extreme, neither hot waves nor cold waves usually lasting long; the weather damper than in the farther north. It is the chief region of Indian corn and apples, hay and potatoes, etc. The southern half shows the beginnings of tropic elements in the seasons, which are not so much winter and summer as wet and dry; in the luxuriance of vegetation and characteristically tropic varieties: in the less bracing atmosphere, and in the bottom lands its languorous oppressiveness; in the domestic architecture, where the obvious desire is to escape heat rather than to ward off cold; and in the productions, such as cotton and tobacco, rice and sugar, sweet potatoes and oranges in the far south.

The Pacific slope, however, is an exception to this, its climate resembling the western coast of Europe much more than the eastern of its own. All the isothermal lines curve sharply northward west of the mountains. From Puget Sound to San Diego there is no extreme range of climate, no such division into quasi-arctic and quasi-tropic as on the eastern slope; though the northern part from its heavy rains is the greatest timber region of the continent north, and the southern a great country of vineyards, almond orchards and other south-temperate products. California reaches from about the

parallel of Boston to that of north Georgia and Mississippi, but has neither the raw, harsh New England climate nor the heavy southern atmosphere, and southern California is a noted warm sanatorium. The high arid plateau of north Mexico experiences extreme alternations of temperature, from 95° to 40°; but on the coasts and below the great Anahuac table-land the region becomes semi-tropic. Sugar-cane, cotton, and coffee now ascend to the lower mountain regions, and in their place, at sea-level, appear pineapples, bananas, etc. Central America from its narrowness and low elevation has an island climate, tropic and pestilential on the shores and along the streams, moderate and healthful on the higher ground in the interior. This and the Antilles are the region of sugar, indigo, cochineal, ginger, vanilla, capsicum, etc. South America, lying on both sides of the equator, has in the central and eastern parts a much less range of climate than North America, the greatest in a single section being found in Argentina, where it is some 30°; over the whole continent the mean annual temperature ranges from 80° to 40°, the midwinter (our midsummer) from 80° to 35°, and the midsummer from 85° to 50°; north Argentina, the Cordilleran section, having, as before, the greatest alternations. The southern west Andean slopes are cooled and equalized by the west winds from the ocean; the northern parts are a tropic desert; but on the different levels of the range are found every climate of the earth from tropic to arctic. The tropic productions and characteristics south of the equator, except as deflected by local conditions, are much like those north of it. The zone reaching south as far as lat. 40° S. has a mean temperature of 71° in the warmest and 53° in the coldest month. There the palm still thrives on the lower basin of the La Plata beside the mulberry and indigo; the pampas and the west coasts of Chile are characterized by beautiful araucarias (the pine of the southern hemisphere), by beeches and oaks, the potato and the arrowroot. The plants in cultivation are a curious blending of the vegetation of the northern and southern United States: wines, olives, oranges, hemp, flax, tobacco, wheat, Indian corn, and barley. The southern limit of the periodical rains reaches as far as lat. 48° S., when the mean temperature of 59° in the warmest and 39° in the coldest month still favors the growth of cereals, and on sheltered spots of the west coast the growth even of the vine and the finer fruits. The zone reaching to the southern extremity of America shows comparatively little difference between the warmest and coldest month, the mean temperature of the one being 41° and of the other 25°; but the low degree of summer warmth produces a marked change in the form of vegetation, which now presents only a few trees, as the beech and birch, and an extraordinary abundance of mosses and ferns. As in passing from the equator to the pole the region of the vegetable world gradually declines, so in climbing from the tropical shores to the ice-covered mountain summits three different climates have been distinguished by the names of *tierra caliente, templade* and *fria* (hot, temperate, frigid). Of these the *templada* extends over those healthy and beautiful regions where a kind of perpetual spring prevails, and green pastures and noble forest trees are found united with the fantastical and gigantic forms of the tropics.

The question of rainfall is difficult to group systematically with that of climate. The mass of the northern continent is in the region of the anti-trades or prevailing westerly winds. The Japanese Black Current, the Gulf Stream of the Pacific, running northeast and striking the polar currents and the cold shores, ice-bound for many hundreds of miles, sends up a great steam of fog which is blown against the wall of the Rockies and sent back by them upon their western slope in a rainfall from 50 inches up to 100 or even more, that makes the northern coast from southern Alaska to northern California one gigantic forest of immense timber. The rainfall on Puget Sound is from 75 to over 100 inches in winter, and the annual average on the Pacific coast of Alaska is 90 inches. In the southern part, along southern and Lower California, the Cordilleran region above the Gulf, and west Mexico, the same winds blow; but the land is too warm to cool and precipitate the vapors to the same extent; and such precipitation as there is takes place mostly on the crests of the coast ranges, the Cordilleran region being mostly semi-desert or wholly so. In the summer the coast ranges are too warm to retain all the moisture of the vapors, which therefore give a little at these seasons, 10 to 20 inches in all to the interior regions.

The Mississippi valley is saved from becoming the most tremendous desert on earth, a second Sahara, by the Gulf of Mexico and the western wall combined. If it had to rely on the Pacific winds it would be utterly rainless; but these westerly winds in the Gulf region set up whirls of cyclonic disturbance which make an easterly eddy, carrying saturated currents in that direction; and these, striking against the Rockies, are turned northeastward through the central and eastern valley, giving it abundant water. This eastward set, however, leaves the western valley only the edge of its course; the far western, as in western Kansas and Nebraska, being rainless for considerable periods and scantily supplied at best. The rainfall ranges from 60 inches on the coast to 30 around the Great Lakes, which add something to the moisture of their district. The same cyclonic movement makes the same easterly eddy in the Atlantic, and the Atlantic coast receives its 40 to 50 inches a year from that source.

Central America is in the region of the trades or easterly winds, and is so narrow that its climate is that of a semi-tropic island. In this region the rainfall is enormous, creating heavy tropic vegetation and increasing to 200 inches at Panama and the northwestern shores of South America, short rivers like the Atrato carrying almost a continental volume of water. All tropical South America is within the trade-wind belt, its moist warm climate creating the enormous forests of the Amazon basin, the oceanic volume of that «river» (rather a huge set of parallel drainage channels in one vast swamp) and its tributaries, and the lesser but still mighty Orinoco. On the western slope of the Andes this portion receives no vapor and is a desert down to north Chili. But in central and south Chile and Argentina the anti-trades begin once more, and North American conditions

are repeated: the westerly winds giving to that coast a mild, equable temperature and heavy rainfall, while the Andes bar nearly all the moisture from the east, and the great southern plains or pampas are a relatively arid steppe.

Taking the continent as a whole, the rainy zone is disproportionately extended in America; and as it stretches over all the zones, the vegetation is remarkably diversified, from the lowly moss of the north to the lordly banana of the tropics. The giant chain of the Andes everywhere rises above the snow-line. From the sterile Peruvian coast, burned by tropical heats, one can look up to summits covered with perpetual snow and ice; and one may climb from the gigantic equatorial vegetation of Quito to heights where only the condor testifies to the existence of organic life as he wings his flight over snow-fields and glaciers. In Peru the culture of cereals is carried on at the height of 12,000, and near Quito at 9,000 feet. The north and south of America have the same length of day; but in the seasons which depend not merely on astronomical but on a variety of local causes, the analogy does not hold and very remarkable discrepancies appear. Thus, for example, the east coast of Brazil has the rainy season from March to September, while Peru, lying under the very same latitude, has it from November to March. Within the tropics the transition from the rainy to the dry season takes place almost instantaneously; but in receding from the tropics on either side the change of seasons becomes more and more gradual till at last, in the polar zones, nature, bound in icy chains, affords for living existence only a short awakening out of a long winter sleep.

(See publications of the United States Weather Bureau, the Canadian Meteorological Office, and the Mexican Weather Service; Greely's 'American Weather,' 1888.)

Flora.— The sections of cultivation have been dealt with already and we shall consider here only the indigenous features. From north to south the general succession is as follows:

The surface-thawed arctic tundra bears only reindeer-moss, blossoming weeds in its brief hot summer, and dwarf willows. From about the Arctic Circle to the southern coast of Alaska, James Bay and the North Saskatchewan, we find shrubby plants, most of them yielding berries; then the universal wood-of-all-work, the famed "Alaska spruce," with clumps of birch and alder: these at first sparsely, then forests of conifers,— larger spruces, pine, hemlock, and fir. This coniferous growth extends in enormous volume down the cool wet Pacific slope to central California; the giant redwoods and sugar-pines, etc., and the huge sequoia, the largest and oldest plant on the earth, being famous everywhere. Eastern Canada is forested with similar coniferous species; so is the United States through Michigan, Wisconsin, and west to Minnesota, to southern Missouri and northwestern Arkansas, and to northeastern Texas and the Indian Territory. The central United States has predominant deciduous (hardwood) trees, such as the oak of many varieties, the beech, maple, elm, chestnut, black walnut, hickory, ironwood, pepperage, red mulberry, etc. In the southern States the yellow pine holds foremost place. The characteristic forms of the southern States are the magnolia, palmetto, tulip-tree, plane-tree, pecan, etc., with the cypress everywhere in the swamps. The Cordilleran woods are chiefly conifers, and on the mountains; on the plains and in the valleys are the yucca, cactus, etc., whose dense, thorny growth is termed chaparral. The wild picturesqueness and even grotesqueness of the cactus forms is noted; and it furnishes food for animals that would otherwise starve on the arid steppes. The north Mexican plateau has little wood except on the mountains. Southward vegetation blends with the tropical forms, and in Central America and the Antilles the most valuable trees are the mahogany and boxwood, and of vegetable products vanilla and ginger.

In South America there is no arctic region; but the great differences in altitudes and the water supply give it a wide range of native production. The immense rainfall and steady tropic heat of the north shore along the Caribbean and in the Magdalena valley create a profuse tropical flora on the lowlands, changing to palms, bamboos, tree-ferns, etc., on the higher levels, and coniferous trees on the mountains. Along the Orinoco the llanos, plains with immensely tall grasses and great single trees, take the place of forests. The vast selvas or swamp forests of the Amazon occupy the heart of the continent. These colossal tropic jungles, often formed into an almost impenetrable web by multitudes of creeping and climbing plants, contain an almost unexploited variety of magnificent trees with the most beautiful ornamental woods,—as rosewood, cocabola, etc.,—products like india-rubber, brazilwood for dyeing, cinchona for medicine, etc. Dense forests of cinchona overshadow the mountain terraces of Quito. South of the selvas are the forests of Matto Grosso, the great Brazilian province east of Bolivia; south of this again, and of the Bolivian Cordillera, is the Gran Chaco, or "great round-up," from the Paraguay to the Andes,— a region of three to five hundred thousand square miles, largely plains, but with heavy forests including the wax-palm, and with tree-like thistles on the lower plains. Now begin the pampas of the lower La Plata, which are fine grassy plains in the northern part, but in south Argentina and Patagonia become semi-arid steppes. The western strip has already been dealt with.

(Gray's 'Synoptical Flora of North America,' 1886-97; Heller's 'Catalogue of North American Plants North of Mexico,' 1900; Sargent's 'Silva of North America,' 1890-1; Britton and Brown's 'Illustrated Flora of the Northern United States, Canada, and the British Possessions,' 1896-8; Berg's 'Physiognomy of Tropical Vegetation in South America,' 1894; Rusby's 'Enumeration of Plants Collected in South America,' in 'Torrey Botanical Club Bulletin,' Vols. XV., XX., XXII., XXV., XXVII.).

Fauna.— The distribution of animal life in America proves by itself what was probable on geologic and physiographic grounds, that the proper division between the two continents is not at the Isthmus of Panama, but at either Nicaragua or Tehuantepec, and that the junction was relatively late. Zoologically considered South America includes also not only Central America and the Antilles, but the Mexican plains and coasts east, west, and south of the plateau of Anahuac. The faunæ of the two con-

tinents have almost no common feature. Furthermore, the North American species are in many respects closely allied to the North Asiatic, while the South American mammalia and birds have but slight affinities to those of any other section of the world, and those of the most general kind; fully four fifths of its species being unknown outside its own limits. North America, with this proviso, in Sclater's and Wallace's classification, is Palaearctic in the arctic regions and for some distance south of the northern ocean and west of Hudson Bay, and Nearctic through the rest of its bulk; while South America, thus extended, is Neotropic. Some authorities, however, from the close affinities of the first two, group them together into one as Holarctic or Triarctic.

In North America, for instance, the fur animals are not very different from the Siberian kinds; the reindeer, moose (called elk in Europe), and bighorn are closely akin to Asiatic congeners; the bison belongs to the buffalo family; the cat family is represented by the panther and wildcat; the wolf family by various classes of wolves, and probably by the Eskimo dog; the bear family by several distinct sorts. The white goat has close foreign relatives; so have the beaver, marmot, rabbit, squirrel, and most of the other rodentia, the weasels, insectivora, bats, and others. The birds, reptiles, and amphibia are nearly all identical in family with Old World groups, and often in species. The fresh-water fish and mollusks of the cold regions of both are generally akin, and sometimes the same, though in the great rivers of the southern half many new forms have developed, the river mollusks being much more numerous and specialized in the United States than in any other part of the world. But there are very notable individual forms. The North American "great cat," variously called panther, catamount, cougar, puma, mountain lion, American lion, etc., has long been specialized in this region; the musk-ox and the skunk are our own, as are the pronghorn and the gopher. And there are still more striking absences where all analogy would lead us to expect strong representation. The horse, camel, and rhinoceros originated in North America as late as Tertiary times, but have entirely disappeared. There is but one marsupial, the opossum, no antelopes, and but one genus of native swine, in Texas and Arkansas.

South America shows a new world. Out of 10 orders of mammalia with 33 families which it contains, 13 families are confined exclusively to it. All its families in two orders, the Primates (monkeys) and Edentates (armadillos, sloths, and ant-eaters), are its own, and five of its nine families of rodents; while of the *Chiroptera* (bats), one family, the *Phyllostomidæ*, which includes the vampire bats or blood-suckers, is peculiar to it. Its deficiencies are equally notable, though less so in some respects than of the northern continent, as it lacks none which originated there. The horse family group is represented only by the tapir, the ruminants only by the llama, and the bears only by the Andean bear of Chile and Peru. There are no Ungulates but a small deer and one genus of swine, no members of the weasel or civet families, and only two small genera of insectivores. The birds, instead of having a wider range as might be thought, are still more individual: 23 families, including hundreds of genera, are exclusively South American, while only three out of its 118 genera of humming-birds, one of its 43 genera of tanagers, eight of its 70 genera of tyrant flycatchers, one of its 14 genera of macaws, four of its 13 genera of pigeons, one of its 12 genera of *Cracidæ* (curassows, etc.), two of its 11 species of goatsuckers, etc., have any habitat beyond itself. Of its wading and swimming birds, 18 of its 24 genera are peculiar to it. The reptiles are much less specialized, only four out of 60 genera being entirely individual, and those of lizards; the species, however, are more peculiar than this would indicate, the boas and scytales being distinctively South American, and the iguana practically so, though known somewhat north of this region. The waters naturally are much less specialized. Of the amphibians only three out of 16 genera are local. The fishes have four families and 17 genera, of which one family with its one genus, and a genus of another, are peculiar to the South American, the resemblances being mainly to the African families. The sirenoids represent extremely ancient forms. The insects are also not so different in form as might be anticipated. But this view understates the specific variations, for on the whole South America is a zoological land apart.

(See 'The Standard Natural History,' Boston, 1885; Alfred Russel Wallace, 'The Geographic Distribution of Animals,' 1876; Merriam's 'Geographic Distribution of Life in America,' in Vol. VIII. of 'Proceedings of the American Biological Society.' For special portions, Cope's 'Crocodiles, Lizards, and Snakes of North America,' in United States National Museum Report, 1898; Apgar's 'Birds of the United States,' 1898; Goode's 'American Fishes,' 1888; Edwards' 'Butterflies of North America,' 1868-88.)

Political Divisions.— The independent States of both North and South America are all republican in government, though it was only in 1889 that Brazil became a republic. The continent is politically divided as follows:

INDEPENDENT REPUBLICS.

America, Discovery and Colonization of. The effective discovery of America was a gradual process, made possible by the first westward voyage of Columbus across the Atlantic and developed by attempts to determine the relation of the lands thus encountered to the Asiatic continent. The body of legends concerning European or Asiatic contact with America prior to the 15th century bears witness only to a vague impression of or conjecture at the existence of land in the western part of the Atlantic Ocean, which led to nothing effective in the way of confirmation of such conjecture or occupation of the territory. The contact by the Norse colony in Greenland in the 11th century with the shores, probably of New England, which the Northmen knew by the name of Vinland, led to nothing more than occasional resort to certain of its facilities such as timber, and cannot be regarded as a discovery in any complete sense. Nothing can detract from the unique distinction of the expedition of Columbus in 1492. The cosmography of his time was in error as to the size of the earth and consequently underestimated the distance intervening between the western limit of Europe and the eastern shores of Asia. But this error could in the nature of things only be brought to light by an actual test by a westward voyage across the Sea of Darkness. This test it is the sufficient glory of Columbus to have furnished and its importance for cosmography cannot be overestimated. Nevertheless, in its relation to America alone, discovery in the complete sense was rather made possible, than achieved by Columbus.

It was under the auspices of the Atlantic States of Europe that development of the results of this voyage was carried on, and of these Atlantic States, Spain and Portugal at first took the leading part. At the time of Columbus' great voyage, Portugal had nearly completed the development of the possibilities of an eastward maritime route to the Oriental trade regions, the goal of maritime endeavor. The Spanish patronage of Columbus naturally led the Spanish Crown to claim for the westward approach to the Indies, thus made possible under its auspices, the same advantages which papal action had secured for Portugal in connection with the eastward route. By a papal bull of 25 September 1493, superseding those on the subject previously issued, enterprise upon the ocean was declared open to both Spain and Portugal, with the understanding that Spain should refrain from infringement upon the Portuguese monopoly of the African coast by using only the westward approach to the Indies. By the Convention of Tordesillas, 7 June 1494, the line 370 leagues west of the Cape Verde Islands was set by the two nations themselves as a division between their respective areas of maritime activity.

Spanish voyages between 1493 and 1502 now skirted most of the island and continental shores of the Caribbean Sea and the Gulf of Mexico, without, however, making much progress in elucidating the connection between these regions and the Asiatic continent, with which they were still somehow supposed to be connected. In the meantime, by the Cabral voyage to Brazil in 1500 and those of the Cortereals to Labrador and Newfoundland in 1500–1502, Portugal found an interest in westward voyages, for she claimed that not only Brazil, but also the regions in the vicinity of the fishing grounds in the north were east of the line of demarcation. The expeditions of Vespucius, Coelho and Jaques, 1501–1503, not merely satisfied Portuguese curiosity as to the extent of their possessions accessible by the westward voyage, by

establishing the southwestern trend of the Brazilian coast, but, what was very much more important, by establishing the continuance of this land mass to a point as far south as the latitude of the southernmost point of Africa, practically ensured the conviction that here was a New World. This was a land mass, insular or peninsular in its connection with Asia on the north, of such extent as practically to constitute a part of the world co-ordinate with Europe, Africa, and Asia. It was to the New World, as thus conceived, that the name America, perhaps a little more than half seriously, was proposed by friends of Amerigo Vespucci in 1507, to be applied, and the name thus applied was but very gradually extended, as the truth became known, to the whole double continent. Spain's great efforts in exploring voyages as distinguished from land expeditions into the interior, were now concentrated upon the search for a strait through, or a passage to the south of, the lands revealed by the voyages since 1492. This was in response to the epoch-making voyage of da Gama in 1497. More accurate acquaintance with the extent of the Asiatic continent developed by Portuguese activities in the Far East subsequent to the voyage of da Gama was a favorable condition for such attempts as the Spaniards were making, and the voyage of Magalhaes in the service of Spain in 1519–22 to the south of the New World revealed the extent of the waters lying between it and the Asiatic continent. This was a fundamental fact, knowledge of which was in large outline logically sufficient to establish the separate continental character of the territory brought to knowledge since 1492. Appreciation of this significance of Magalhaes' voyage was slow in developing, however, and not until after exploring conquests of the western shores of the continent from bases on the eastern shore, like the conquests of Mexico and Peru by Cortez and Pizarro in 1519–21 and 1531–33, Almagro's and Valdivia's Chilian expeditions in 1535–40, and expeditions like those of Cortez and Alarcon and Coronado to Lower California and up the Colorado River in 1526–40, that the outline of the continent on its western shore was traced out as far as Southern California. The coast north of this region was only reached and effectively made known by a succession of voyages covering a considerable space of time and headed by representatives of different nations. Most prominent in this enterprise were the expeditions of Drake in 1577–80, which probably reached the northern California coast; Bering, the Russian, in the strait bearing his name and on the Alaskan coast, in 1741, and Vancouver on the coast of what is now British Columbia in 1792. The eastern shore of the continent — unless we include the voyage of Gomez from Labrador to Florida in 1525, which was not followed up — was outlined by Spain only as far north as Chesapeake Bay, the remainder being the scene of French and English activity after the Spanish power was becoming embarrassed in Europe.

After the voyage of Magalhaes in 1522, Spanish interest in the New World concerned itself rather with the task of exploring the interior of the regions whose boundaries Spanish voyages had skirted, than with further extension of the lines of inclusion. The glittering success of Cortez in Mexico in 1519–21 was responsible for many attempts in imitation of such an achievement, and in the course of these attempts much knowledge was attained of the conditions in the interior of the continent. Pizarro's conquest of Peru led on to the exploration and attempted conquest of Chile and to the crossing of the Andes and the descent of the Amazon by Orellana in 1541. The La Plata system was explored by Sebastian Cabot and Diego Garcia in 1527–30. In the northern continent, Florida had been discovered by Ponce de Leon in 1512 and proved a part of the continent by Pineda, who also made acquaintance with the Mississippi in 1519. In the course of the wandering of such parties as those led by de Leon, Narvaez, Cabeza de Vaca and Coronado from 1512 to the middle of the century, much of the interior was seen as far north as the Missouri and Ohio systems, but only the extreme southeast and southwest portions, that is, California and Florida, saw any attempt by Spain to occupy the territory thus wandered over. The task of administering and exploiting what she already had was sufficient to absorb what energy could be spared from European occupations.

France and England, in the meantime, were becoming less and less inclined to respect the claims of Spain in any direction not backed up by present physical force, and more and more inclined to take up a line of aggression in maritime endeavor, not only for the sake of weakening the general position of Spain, but also because of the stirrings of individual enterprise within their own populations. It was only under these circumstances that England began to make use of the claim based upon the Cabot voyages of 1497–98. Conditions inclining the government to a policy of respect for the claim of either Spain or the Pope were now wholly changed, and as against any right to territory west of the line of Tordesillas, England pursued the policy that occupation must, within a reasonable time, be added to discovery to constitute a valid title to territory in the New World. According to this criterion, the achievements of England and France in the 16th century can only be regarded as preliminary or preparatory in character. In each case internal strife at home and the exigencies of the European situation prevented the achievements of discovery and incipient settlement from being followed up. Nevertheless they served to reveal in an effective way that portion of the continent in which conditions for transplantation of European institutions and life were most favorable. The stretch of shore left unoccupied was comparatively small and the great work of France was extensive, and rapidly spread over the interior accessible by water-routes from the shore. While England's great work was the permanent and slow-expanding settlement of the strip between the coast and the mountain-barrier of the Alleghanies.

In 1524 Verrazano, a Florentine in the service of France, coasted from North Carolina to Newfoundland, and in 1534–41 the first French attempt at settlement was made under Cartier and Roberval, and though it was not at this time maintained, the foundation was thus laid for the French claim to the territory of the Saint Lawrence system. Attempts to invade the undoubted sphere of Portugal by Villegagnon in Brazil in 1555, and of Spain by Ribaut and Laudonniere in Florida and South Carolina in 1562,

were promptly suppressed. So that when, at the beginning of the 17th century Frenchmen were in a position to take up transatlantic activity once more, the Saint Lawrence basin naturally became the scene of their endeavors. From Port Royal in Nova Scotia in 1603, headquarters were shifted in 1607 to Quebec, and once established at one end of the great interior waterway system, and headed off from southward expansion by the hostility of the Iroquois, the line of least resistance led naturally to the interior by the west. These circumstances, coupled with the character of the emigrating population, account for the most signal achievement of the French in the New World — exploration of the continental interior. This went on coincidently with the process of colonization and thereby a fundamental characteristic of New France on the mainland was illustrated — the attempt by the government to nourish a true colony in eastern Canada, while the adventurous population, missionary, and fur-trader, overran the surface of the great interior. Trails were made by Nicollet in 1634 as far as the Illinois country by the Lakes and the Fox River route, by Radisson and Groseilliers in 1658–59 as far as Lake Superior and the Hudson's Bay region, by Joliet and Marquette in 1673 to the Mississippi. And by 1682 La Salle had opened up the connection between the Gulf of Mexico at the Mississippi's mouth and the Gulf of Saint Lawrence. By 1699 a French settlement was planted in Louisiana and in 1718 New Orleans was founded.

With England, the order of proceedings was different. Exploration of new regions was a preliminary to their filling up with settlers and bursts of exploring activity occurred in the intervals of the great stages in the process of colonization. The Cabot voyages gave her the basis of the claim to the continental shore to the north of Florida, but her first exploring activities were in connection with the search for the northwest passage to the Orient by such commanders as Davis and Frobisher in 1576–78 and with the attempt to occupy Newfoundland by Gilbert in 1579. With the career of Raleigh, the English maritime enterprise takes definite beginning in the colonizing line with the attempt at Roanoke in 1585, and from then till well into the 18th century English exploring activity was mainly concerned with the coast between Florida and Newfoundland, the basis of her colonies on the main. This was as characteristic of the English career in the New World as the French method of rapid and extensive spread from an undeveloped base. In the course of occupation of the coast, the English found themselves preceded in the strategic regions of the Hudson and Delaware valleys by the Dutch, and falling back on the principle of prior discovery alone, which, as against Spain, she had disregarded, made conquest of the New Netherlands settlement in 1664, as an invasion of the right to the whole, claimed by virtue of the Cabot voyages. British interest in the interior awoke in the 18th century, and, mostly under colonial leaders, British hinterland was extended to a hostile contact with the French claims to the interior based on discovery and exploration of the Saint Lawrence system. This being settled, by the elimination of New France from the continent in 1763, English exploring activity found its scene, after the separation of the seaboard colonies with their westward extensions to the Mississippi, in the extreme northern part of the continent, with the territory of the Hudson's Bay Company as the base. Here in the later years of the 18th century the early expedition of Verendrye to the Canadian Rockies by the Saskatchewan in 1741 through the interior of the Canadian Northwest was followed up by Hearne in 1770 and Alexander Mackenzie in 1789.

The areas in the New World within which the colonizing activities of the European Atlantic States were carried on conformed in a general way to the scenes of their earliest contact and activity. Portuguese colonization in the New World was limited to Brazil, the only portion of the continent within the limits marked out by the line of Tordesillas. Spanish activity radiated from the Caribbean archipelago in all directions and included the greater part of habitable South America, Central America, and the southern portion of the North American continent. French colonies were to be found among the West Indies, but the greatest extent of French settlement was in the neighborhood of the Saint Lawrence system, while the English, late comers as they were, occupied strategic points among the islands and stretched along the continental shore from Florida to the Kennebec.

In the list of participators in the work of colonizing the New World there must be added to the European Atlantic States already mentioned as conspicuous in discovery and exploration, Holland and Sweden. But the brevity of the duration of these attempts hardly entitles them to a place of equal significance with the other four as colonizers in America. The Swedish colony founded in 1637 on the banks of the Delaware was regarded by the Dutch as an intrusion on their rights and fell victim to Dutch conquest in 1655. The Dutch enterprise on the Hudson and Delaware was in turn held by the English as equally an intrusion on English North America and the Dutch were dispossessed in 1664 by the same means as they had themselves employed upon the Swedes. During their development of New Netherlands the Dutch were not successful in planting the colony firmly on an agricultural basis, the fur trade proving attractively profitable. A system of colonial government in too close dependence upon a clumsily working confederate government at home and a system of local government which repressed individual initiative retarded the development of the colony. A few islands in the West Indies and a small stretch of the northeastern coast of the South American continent still remained — and do yet — as Dutch colonies in the New World.

Portugal began her American colonization in 1531 in Brazil, but was unable to give it the requisite attention until the 18th century. In the meantime the comparative freedom from restraint enjoyed by the colonizing population had exercised a developing effect, and, putting in practice lessons in regard to the exploitation of a tropical colony learned elsewhere, Portugal developed a colonial establishment stable enough to afford a refuge for the House of Braganza during the period of Napoleonic occupation of the Iberian peninsula. In 1821, the Brazilians with the concurrence of their regent, himself of the royal house of Portugal, proclaimed their

independence from the Crown of Portugal, and this independence was subsequently ratified by treaty.

The Spaniards began colonizing with the second voyage of Columbus and the islands of the Caribbean, particularly Haiti and Cuba, became the scenes of an exploitation of the superficial riches of the tropics which served as bases for exploring conquests to the territory of the mainland. The policy of Spain towards her wide domain in the New World, as worked out in the 16th century, not in abstract theory, but in combination of theory with practice, was but little more illiberal, but considerably less intelligent than that of other States. But the climate of the part of the New World falling to them was not conducive to the steady, strenuous persistence necessary for the building up of permanent wealth-producing communities. Nor were the original characteristics of the colonizing population calculated to make success in such a career likely. The natives were not able to offer stubborn resistance to the rapidly moving enterprises of the conquistadores. A certain tendency to amalgamate with the natives — a tendency which weakened the stronger without strengthening the weaker race — did not prevent the evasion of the laws intended to protect the natives from the rapacity of their conquerors and to keep the two opponents of the official class in balance against each other. The too rapid early successes in the realm of military conquest and the easily won response to the search for the precious metals still further unfitted the Spaniard for what modern colonizing peoples are finding the most difficult of tasks — the intelligent exploitation of the possible economic resources of a tropical region where the available labor supply is for various reasons inefficient according to European standards. Nevertheless, though the Spanish dominance over such a great part of the New World could not guarantee prosperity to this Empire, it was rather the shock given by the Napoleonic attack on the mother country and its consequences on Spanish internal warfare than the inherent strength of the separate divisions of Spanish-America, that accounts for the revolt of the greater part of this Empire in the first three decades of the 19th century. And at the same time that political separation was taking place, Spain in Europe stood in such need of political help from England that a commercial invasion of Latin-American markets could not be prevented. With this once accomplished and the Napoleonic danger passed, the influence of England was publicly and privately used to obstruct all attempts from Spain to re-unite the scattered fragments of the once mighty power in America. The sluggish development, to call it by no worse a name, which characterized what remained to Spain of dominion in America between the Latin-American revolts and the wresting of Cuba and Porto Rico by the intervention of the United States in 1898 illustrates the degree of effectiveness of Spanish colonial policy according to modern economic standards.

French colonization in America received much attention from the home government and the French temperament was one adapted to success in dealing with the natives, and in amalgamation with them in preserving the elements of strength. But on the other hand the over-zealous and intemperately exercised interference from home frequently nullified all the good that the lavish furnishing of assistance in materials and in military protection did to the fortunes of the colony. The climate was as excessive in its rigor as that of New Spain was in the opposite direction. The hostility of the Iroquois, fiercest of all the native tribes, obstructed expansion to a more favorable clime and made extensive use of a vast forest domain for the fur-trade a more easy and attractive program than the jog-trot business of intensive agriculture and the development of permanent communities on the frontier for which latter task lack of the habits of initiative in self-government unfitted the colonizing population. The only colonizing material in the French people capable of developing such traits — the Huguenots — was peremptorily excluded from New France. So that when the English expansion had at length come into collision with the borders of the French forest preserve in the interior, New France on the continent was capable, by reason of the feudal and military force pervading its population, of effective resistance against the superior numbers of the English settlements co-operating but clumsily with each other. As between the French and British empires as world-units, however, there was soon no question of superiority, and France was definitively excluded from the continent as the result of the Seven Years' war (q.v.). The French possessions in the West Indies, acquired in various ways during the 17th century, remain to her, and make of her to that extent an American power.

The colonizing work of England in America belongs to the colonial period of United States history (q.v.). In broad outline, her policy toward her American domain was one which, whether with design or not, allowed wide scope for individual and local initiative. The English population afforded good colonizing material. The Indians gave no such serious trouble as did the Iroquois in the case of the French in the early stages of their colonizing. Defense against European attacks upon the colonies was effective. As builders of settlements in the New World, the English were eminently successful. In devising, or at any rate, applying a system of political connection between the home government and the colonies, the English reached an unfortunate place in their internal political development coincidently with a critical stage in the relations of colonies and mother country. The strain at that time and under those circumstances brought upon colonial loyalty proved too great and by the separation of the 13 Atlantic seaboard colonies, Great Britain's power in the New World was cut down to control of certain important West India islands and the area so recently wrested from France. Under the new spirit of the British Empire which appeared i the 19th century, these possessions have been s developed and bound in sentiment to the inter ests of the mother country that Great Britain stands second only to the United States as an American power.

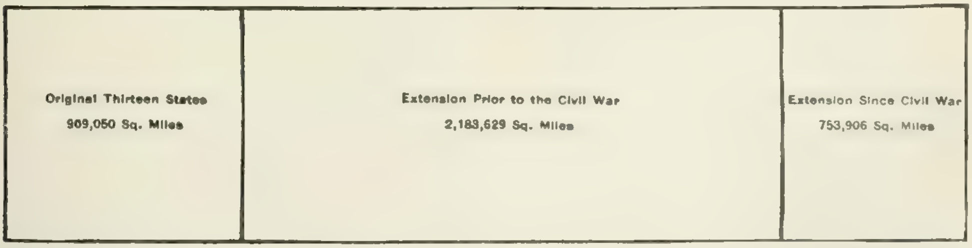
Charles Worthen Spencer,
Professor of History, Colgate University.

America, United States of. Half of the entire land area of the world, estimating it at 51,410,700 square miles, is in the possession of four nations, one of these four being the United States of America (q.v.). The territory of this nation covers 3,846,595 square miles. Each of the three other nations possesses a greater area, the British empire (q.v.) covering 8,964,884 square miles; Russia (q.v.), 8,660,395; and

China (q.v.), 4,277,170. The territory of the United States is all contiguous, with the exception of outlying insular possessions. That of the British Empire is widely scattered. Russia and China have each the advantage of contiguity of territory, but Russia is one of the least developed of civilized nations, while China as yet has scarcely begun the march of modern progress. The history of the United States has been marked by a territorial expansion (see UNITED STATES — TERRITORIAL EXPANSION) which is wonderful on account of its rapidity and the fact that it is the result, almost entirely, of peaceful acquisition, a very large proportion of the acquired territory having been ceded by other nations, as in the case of the Louisiana



Purchase in 1803, and of the Alaska purchase in 1867, the first of which nearly doubled the area of the country at that period. The 13 British colonies which began the war for independence in 1776, and which Great Britain was forced to recognize as the United States of America in 1783, comprised a territory of 909,050 square miles. Briefly told, the story of expansion follows: By the Louisiana Purchase (q.v.) in 1803 the United States acquired from France, for $15,000,000, a territory covering 875,025 square miles. Oregon, 288,689 square miles, was acquired under what is known as the Florida treaty (q.v.) in 1819; and the same year witnessed Spain's cession of Florida, 70,107 square miles, for a consideration of $5,000,000. Texas, an independent republic with 389,795 square miles of territory, was peacefully annexed in 1845. Mexico ceded 523,802 square miles of territory in 1848, for a consideration of $15,000,000, and the payment of claims held by American citizens against the Mexican government, amounting to $3,250,000. By the Gadsden Purchase (q.v.) of 1853, so called because it was negotiated by James Gadsden, United States minister to Mexico, 36,211 square miles, forming the southern part of the present territories of Arizona (q.v.) and New Mexico (q.v.), were purchased from Mexico for $10,000,000. Thus, down to the period of the Civil War of 1861–5, the area of the United States had been increased by 240 per cent. The aggregate amount paid for ceded territory, including $499,768 interest on the $5,000,000 paid for Florida, was $48,749,768. After the Civil War Russia ceded Alaska (q.v.) in 1867, and the United States secured 599,446 square miles for $7,200,000. The Republic of Hawaii (q.v.) declared for annexation in 1897 and now forms part of the United States as one of the territories. Its area is 6,740 square miles. Following the nation's success in the Spanish-American war of 1898 it acquired in that year the island of Porto Rico, 6,740 square miles; Pine Island, 882 square miles; and Guam Island, 175 square miles. In 1899 the Tutuila group of the

Samoan Islands, 73 square miles, was acquired; and Spain ceded, in consideration of $20,000,000, the archipelago known as the Philippine Islands (q.v.), which has an aggregate area of 143,000 square miles. The total extension of United States territory during the century amounted to 2,937,535 square miles, a territorial growth of 323.14 per cent, at a cost for ceded territory of $75,949,768.

Multiplication of constituent States has been fully as rapid as extension of territory, the vast regions acquired being opened up to settlement under conditions inviting large immigration. The first of the new States, however, was Vermont, whose territory had been claimed for years by New York and several of the New England States. Vermont was admitted to the Union in 1791. Two other States have been created within the territory covered by the

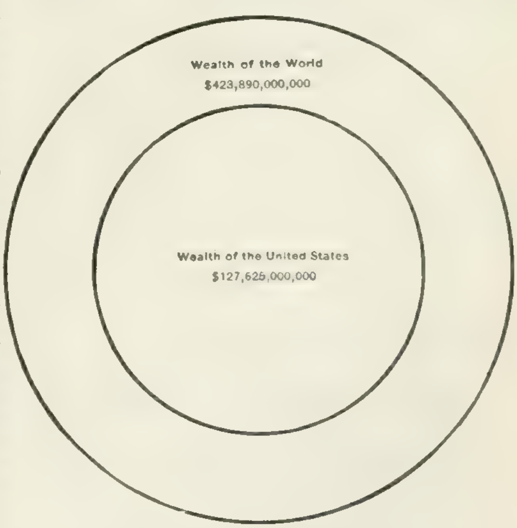
original 13, namely, Maine, detached from Massachusetts and admitted in 1820; and West Virginia, formerly included in Virginia, which State, already divided physically into two sections by the Alleghany Mountains, was divided in sentiment at the beginning of the Civil War, the western section adhering to the Union cause, and receiving recognition as a State in 1863. The full list of States added to the original federation, together with the respective dates of admission, follows: Vermont, 1791; Kentucky, 1792; Tennessee, 1796; Ohio, 1803; Louisiana, 1812; Indiana, 1816; Mississippi, 1817; Illinois, 1818; Alabama, 1819; Maine, 1820; Missouri, 1821; Arkansas, 1836; Michigan, 1837; Florida, 1845; Texas, 1845; Wisconsin, 1848; California, 1850; Minnesota, 1858; Oregon, 1859; Kansas, 1861; West Virginia, 1863; Nevada, 1864; Nebraska, 1867; Colorado, 1876; North Dakota, 1889; South Dakota, 1889; Montana, 1889; Washington, 1889; Idaho, 1890; Wyoming, 1890; Utah, 1896.

Growth of population rather than acquisition of territory has been, of course, the occasion for the creation of States. With a few exceptions all of the States admitted to the Union were primarily organized with territorial governments, responsible to the federal authority at Washington, and remained territories until possessed of population sufficiently large to justify statehood. The first census of the United States, taken in 1790, showed a total population of 3,926,214, which exceeds by less than half a million the population of New York city, as shown by the census of 1900, and which is probably exceeded by the population of that city in the present year — 1904. The total population of the country in 1900 was 76,305,387. The increase, as shown by each decennial census, ranged between 36.4 per cent and 20.7 per cent, the general tendency being toward a reduced percentage as the country grows older and becomes more thickly settled. The average decennial increase from 1790 to 1900 is 30.9 per cent. Following are the figures showing the population at the close of each decade: 1790, 3,926,214; 1800, 5,308,483; 1810, 7,239,881; 1820, 9,638,453; 1830, 12,866,020; 1840, 17,069,453; 1850, 23,191,876; 1860, 31,443,321; 1870, 38,558,371; 1880, 50,189,209; 1890, 63,069,756; 1900, 76,305,387. The population in 1904, as estimated, is about 84,000,000.

Immigration from foreign countries has naturally been a large factor in the increase of population. During the period from 1821 to 1850 the total number of immigrants arriving in this country was 2,455,812. Of this number 1,038,824, or 42.3 per cent, were from Ireland, while Great Britain sent 367,933, making the

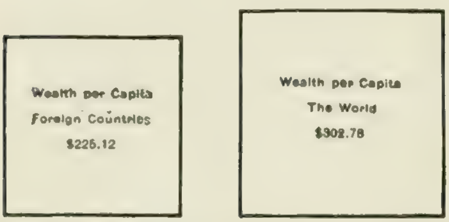
total contribution from the United Kingdom something more than 57.2 per cent of the entire foreign addition to the population of the United States. The great tide of German immigration began during the same period, the number of German immigrants being 593,841. There was also a considerable influx of the Scandinavian element, Norway, Sweden and Denmark send-

ing 16,966. Italy had made a small beginning with 4,531; and there was a mere driblet of 1,393 from Russia and Poland. Canada (q.v.) and Newfoundland (q.v.), which have supplied a large and valuable element of the population, began their contributions during this period with 57,624. Of the 2,598,214 immigrants who arrived during the decade, 1851–60, Queen Victoria's subjects constituted 51.5 per cent, not counting the 59,303 who came from Canada and Newfoundland; there were 914,119 from Ireland and 423,974 from Great Britain. Germany outnumbered Ireland in her representatives, sending 951,667. The Scandinavian countries sent 24,680; Italy, 9,231; and the Sclavonic countries, 1,621. During the ten years from 1861 to 1870 the tide of immigration fell off to 2,314,824, owing largely to the conditions existing here as a result of the Civil War. The quota from England and Scotland, however, showed a very large increase, the figures being 606,896; Canada and Newfoundland sent 153,871, as against 59,303 during the preceding decade; the Scandinavians numbered 126,392, an increase of more than 500 per cent; the Italians made a noteworthy increase with 11,728, while Russia and Poland's contingent increased to 4,536. This decade brought the first perceptible wave of the large tide which has flowed from Austria-Hungary, the number from that country being 7,800. While the German and Irish immigrants were greatly decreased in number they constituted a very large proportion of the whole, the Germans leading the list of nationalities with 787,468, and the Irish coming third with 435,778. An increase of nearly half a million immigrants is shown by the record for the ten years from 1871 to 1880, the number for that decade being 2,812,191. Germany continued in the lead, but with a further reduction in her figures. The German immigrants numbered 718,182. Ireland was a trifle better represented than in the previous decade, sending over 436,871, while Great Britain fell off to 548,043. The tide from Canada and Newfoundland was more than doubled, with 383,269 as the actual figures. Scandinavian immigrants numbered 243,016, or nearly double the number for the preceding ten years, while Austria-Hungary, Italy, Russia and Poland all made an immense increase in their representation, Austria-Hungary sending over to this country 72,960 persons; Italy, 55,759, and the Sclavic countries, 52,254. Immigration touched high-water mark in the record for the period including the years 1881–1890. The figures were 5,246,613. Germans led the list with 1,452,970. The immigration from other countries, in the order of the larger figures was: Great Britain, 807,357; Norway, Sweden and Denmark, 656,494; Ireland, 655,482; Canada and Newfoundland, 392,802; Austria-Hungary, 353,719; Italy, 307,309; Russia and Poland, 265,088. Something more than half of the immigration for the decade ending with 1890 was from Italy, Russia and Poland, and Austria-Hungary, in the order named. The Italians numbered 651,899; Russians and Poles, 602,010; Austrians and Hungarians, 592,707. Germany supplied 505,152; the Scandinavian countries, 371,512; Ireland, 300,179; Great Britain, 207,019; and Canada and Newfoundland only 3,064. Besides the countries named other countries have supplied from 180,355 to 374,703 immigrants for each of the periods, but those named have been selected for mention because of the influence which their emigrants must necessarily wield in determining the general character of the present population of the United States. The proportion of foreign born people to the entire population as shown by each census during the period covered is as follows: 1850, 9.7 per cent; 1860, 13.2 per



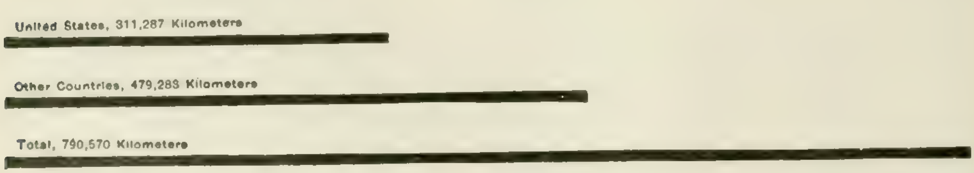
cent; 1870, 14.4 per cent; 1880, 13.3 per cent; 1890, 14.8 per cent; 1900, 13.7 per cent. The proportion of those native born, but of foreign parentage, can be shown only from 1870, as follows: 1870, 28.2 per cent; 1880, 29.8 per cent; 1890, 33.0 per cent; 1900, 34.3 per cent. See IMMIGRATION TO THE UNITED STATES.

By far the wealthiest country in the world, the United States possesses 30.5 per cent of the world's entire wealth, nearly double Great Britain's share, nearly two and a half times that of France, and more than three times that of Germany. The amount possessed by this country is, in round numbers, 127,625 millions of dollars, divided as follows: Farms, $20,710,000,000; railways, $11,300,000,000; buildings, $22,230,000,000; furniture, $8,000,000,000; merchandise, $7,815,000,000; bullion, $1,175,000,000; sundries, $19,695,000,000. The wealth per capita of the population is $1,519.34; that of the entire world being $302.78; and that of other countries than the United States, $225.12. The annual production of wealth as shown by the census of 1900 is $18,161,189,533, the manufacturing industries producing more than 70 per cent. The figures are: Mineral products, $1,257,732,261; farm products, $3,764,177,706; manufactures, $13,039,279,566. There is a large surplus production,



the preponderating element of which consists of cotton, breadstuffs and provisions, this finding a ready market in foreign countries and making the balance of trade very large in favor of this country. The total exports of merchandise for the fiscal year ended 30 June 1903 were $1,420,138,014, including foreign merchandise reshipped abroad to the amount of $27,906,377. Breadstuffs and provisions constituted about 35 per cent of the total value, and represented about 13 per cent of the farm product of the country. The total imports of merchandise for the same year were $1,025,751,538, the balance in favor of the United States being $394,386,476. See UNITED STATES — COMMERCIAL DEVELOPMENT OF THE; UNITED STATES — ECONOMIC DEVELOPMENT OF THE.

RAILWAYS OF THE WORLD IN 1900



Canals (q.v.) were an important factor in the early development of the country, and although they have been very largely superseded by the railways, they continue to assist materially the vast domestic commerce, and constitute a considerable element in transportation interests. Of the many canals which have been constructed in the United States 23 are ship canals, several of these being designed to make more available certain natural waterways of which they are extensions. There are 70 canals in all, including the new Illinois and Mississippi Canal, begun in 1902, but not completed in 1904. The total length of these artificial waterways is 3,627 miles. Most of the canals are intended for boats, barges and other light craft. Some of them have not been in use during recent years, but it is by no means certain that they will be abandoned, especially in view of the fact that the desirability of canal improvement has received recognition and the work of canal construction continues. The most important canal undertaking of all history is that of uniting the Atlantic and Pacific oceans by cutting through the isthmus connecting North and South America, a work which the United States government proposes to carry out with the most expedition possible. See PANAMA CANAL.

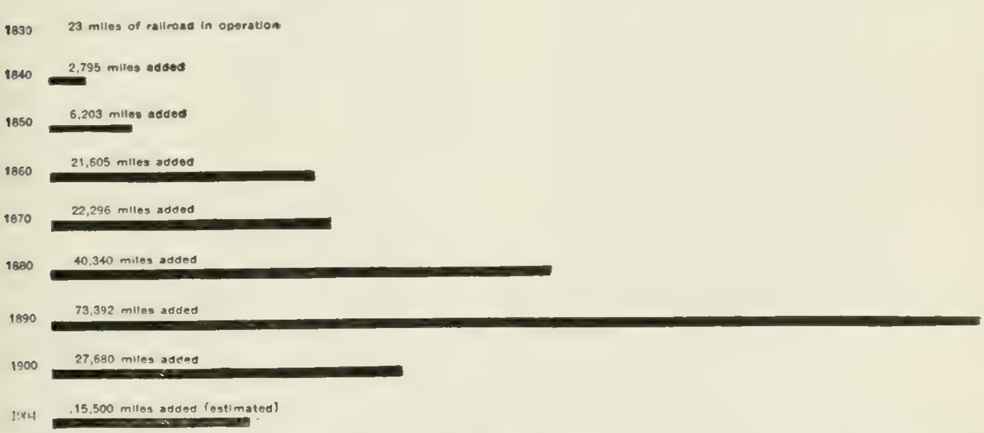
No country is the world possesses so many and so far-reaching railway systems as those of the United States. Statistics for 1900 show that of the entire length of railways in all parts of the world this country has considerably more than one-third — 39.3 per cent; in fact, the estimated number of miles of railway in operation in the United States in 1904 is 210,000. More than half of this mileage has been put in operation since 1880. The story begins with 23 miles of railway in 1830; and the additions have been as follows, by decades: 1840, 2,795 miles; 1850, 6,203 miles; 1860, 21,605 miles; 1870, 22,296 miles; 1880, 40,340 miles; 1890, 73,392 miles; 1900, 27,680 miles; 1901–4, 15,500 miles, estimated. The capital stock of the various railway companies aggregated, in 1904, $6,355,207,335; the gross earnings were $1,908,857,826; the net earnings were $592,508,512; and the total amount of dividends declared was $190,674,415.

The number of miles run by passenger trains was 429,014,116; the number of passengers carried was 696,949,925; and the total movement of passengers was 20,895,606,421. The number of miles run by freight trains was 548,680,595; the freight carried aggregated 1,306,628,858 tons; and the total freight movement was 17,292,198,079. Among speed records made the highest was 4.08 miles in 2 minutes, 40 seconds, on 18 Feb. 1901, near Screven, Ga. This is a speed of 107.09 per hour. A train maintaining this rate of speed could make a complete circuit of the globe at the equator in about 6½ days. See AMERICAN RAILROADS.

Means of communication bear as important a relation to the material development and prosperity of a country as do means of transportation (see RAILWAY TRANSPORTATION), and in the magnitude of telegraph and telephone interests the United States holds a leading position, while the post-office department of the government renders service which is excelled in only a few particulars by that of one or two foreign governments. On the other hand the postal affairs of the United States have their own points of excellence, and are subjected from time to time to such improvement as study and experience suggest. For the telegraph service of the country there existed in 1901 systems using 1,156,998 miles of wire, stretched over 219,938 miles of country. These afford means of instant communication with every part of the continent, and, by connection with the thousands of miles of submarine cable, with every country in the world. The number of messages transmitted in 1901 was 83,555,122. For telephone service there are 1,354,202 miles of wire, arranged in 508,262 circuits. They connect 1,348 exchanges and 1,427 branch offices. In addition to the public telegraph and telephone wires there is a large mileage of wires for both telegraph and telephone service which are the property of railway and other corporations, firms and individuals. The increasing use of the telephone has had an effect upon the growth of the telegraph interest, which nevertheless has a large share in the general increase which is felt by all enterprises identified with public convenience.

The history of the postal service of the United States from 1837 to the close of the fiscal year ended 30 June 1903, shows a public convenience maintained at an almost constant expense to the government in excess of the revenue derived from it. In the entire period the revenue exceeded the expenditures in twelve years only, namely, in 1837, 1838, 1839, 1840, 1842, 1843, 1844, 1845, 1849, 1850, 1851, and 1866. The revenue has grown from $4,945,668.21 to $134,224,443.24; and the expenditures from $3,288,319.03 to $138,784,487.97. While the service is conducted at a loss which has to be made up from the general revenues of the government, it must be remembered that the government itself employs it to a very large extent, free of postage, and thus the apparent loss is made up in large degree, if not altogether. For instance, the number of pieces of first class matter carried free for the government in the year 1902–3 was 153,233,677, which, at the minimum, represents $3,064,670.06 in postage. It is safe to add 25 per cent to this sum, which would make the amount $3,830,837.57, or within $729,207 of the deficiency for that year. The number of post-offices in the United States is 74,169, which number does not include the branch post-offices and sub-stations in large cities, of which there are several thousands. The force employed is immense, the free delivery in cities alone employing 19,542 carriers, and the rural free delivery routes an additional 15,119. The estimated number of pieces of matter passing through the mails during the year 1902–3 included 4,262,933,677 pieces of first class matter; 770,657,590 postal cards; 2,615,685,614 pieces of second class matter, or newspapers sent out from the offices of their publication; 1,053,637,057 pieces of fourth class matter, such as books, pamphlets, circulars, etc.; 93,380,005 pieces of fourth class matter, consisting of merchandise, etc.; 60,001,332 pieces of first class matter sent to foreign countries; and 31,171,413 pieces of all other matter sent to foreign countries; making a grand total of 8,887,467,048 pieces. These figures are beyond ordinary comprehension, but their vastness may be appreciated by estimating the size of each piece of matter mailed as that of an ordinary letter envelope. They would cover a plain about seven miles square, or larger than any ordinary town or city. If laid in a belt along the equator they would encircle the globe with a girdle 112 feet

RAILROAD EXTENSION BY DECADES



wide, or twice the width of an ordinary street. See POSTAL SERVICE IN COMMERCE.

The care and transfer of money is a matter of stupendous importance in a country of such vast wealth and productiveness. It rests mainly with the banking interest, as a matter of course, and this is another of the immense interests of the country. A great amount of money is transferred, however, through the money order department of the post-office, as well as through the express companies, which constitute another very large interest, and through the telegraph companies. The amount of money transferred through the money order department of the post-office during the fiscal year 1902–3 was $353,627,648.03. This aggregate represents mainly small transactions, and bears only a small proportion to the exchange business of the banks. The total number of banks in the United States in 1903 was 18,514, divided as follows: State banks and trust companies, 8,545; private banks, 3,902; savings banks, 844; national banks, 5,223. The total capital of these institutions was $1,652,700,362; and the total deposits were $11,246,266,227. See BANKS AND BANKING; MONEY.

In this presentation of the area, population, wealth and productiveness of the United States there is seen the largest development of material resources ever known under any form of government, and it is due in a great measure to the beneficial influence of that republican form of government under which the United States has grown to be one of the most powerful as well as the most prosperous of nations. The great interests of which mention has been made have been fostered and guarded by a government chosen by the voice of the people, and returning to the people at comparatively short intervals for a renewal of the authority confided to it. The character of the people becomes therefore a matter worthy of study. As already shown the growth of population has been considerably accelerated by immigration from other countries. The incoming elements have been widely distributed, and absorbed and assimilated to a marked degree, especially in the succeeding generation. Compulsory education (q.v.) of the young has been a potent factor in this work, and the privileges of citizenship together with religious freedom (see UNITED STATES — CIVIL AND RELIGIOUS LIBERTY IN THE) have had a full share in it. There is no country in the world where churches of every denomination are found in greater proportion to the population, and there is no country where so many large and self-supporting congregations of every denomination exist. While there is no government support given to any church, nor any legal enactments which interfere with a free choice of any religion or no religion, there is not only full protection for the peaceful worshipper, but also a recognition in law of the sacredness of the name of the Deity and of the day in each week set apart for worship. If more interest is taken in education than in religion it is because all intelligent classes regard education as an element of growth, while the religious class, to a large extent, regard it as a part of religion. Census reports show in their tables relating to illiteracy a reduction of illiterates for each decade since 1880, the proportion of illiterates falling off steadily among the native born population, including colored people and Indians. Between 1890 and 1900, however, there was increase in the proportion of illiterates among the foreign-born population, which can be easily traced to the changed character of immigration (q.v.). The percentage of illiteracy to the total population, even since the acquisition of the Philippine Islands, and the coming of more ignorant classes of immigrants, is much less than in any other country. For complete account of the history and development of the United States see under UNITED STATES.

FREDERICK W. WEBBER, M.A.

America, the American national hymn, written in 1832 by the Rev. Samuel Francis Smith. The air to which it is sung is that of the English national hymn, 'God Save the King,' the composition of Henry Carey in 1742. See NATIONAL HYMNS.

America, the name of the schooner yacht winning the international yacht race of 1851. The prize obtained, a silver tankard, has since been known as the "America's Cup." See YACHTS AND YACHTING.

America, Prehistoric. See ARCHÆOLOGY, AMERICAN.

American Academy of Medicine, an organization formed in 1876 to encourage the proper educational preparation of physicians. Membership about 1,000.

American Academy of Political and Social Science, an organization formed in 1889 to promote scientific study of the social sciences.

American Allspice. See CALYCANTHUS.

American Aloe. See AGAVE.

American Antiquarian Society, an association organized in 1812 at Worcester, Mass. The object of the society is the study and preservation of the antiquities of America, and the advancement of art and science throughout the world. Its library includes over 100,000 volumes, including a large number of the rarest Americana, very complete files of American newspapers, and a rich collection of manuscripts, and its 'Proceedings' have been published semi-annually since 1849. It maintains an important museum of antiquities, gathered in all parts of North, South and Central America.

American Anti-Slavery Society, The. See ANTI-SLAVERY SOCIETY, THE AMERICAN.

American Art. See ART, AMERICAN.

American Asiatic Association, an organization formed in 1898 to foster and safeguard the commercial interests of the citizens of the United States, and others associated therewith, in Asia and the East. Membership 280.

American as Official Designation. In June 1904 an order was issued by Secretary of State Hay that on all new record-books, seals, etc., used by representatives of the United States in foreign countries there should appear the words "American Embassy," "American Legation," etc., in place of "Embassy of the United States," "Legation of the United States," etc., previously employed. The usage thus applied to all diplomatic establishments and consular officers had been followed by Secretary Hay when

ambassador to England, his position being that all countries composed of "United States," for example, Mexico, Brazil, Colombia, etc., were described by the geographical, not the political name of the country.

American Association for the Advancement of Science, a society originally known as the Association of American Geologists, founded at Philadelphia in 1840. In 1842 it added Naturalists to its name and was known by this title until 1847, when the present organization was formed. During the past 50 years the names of practically all the leaders of American science have been on the register of the association, and the 52 volumes of its 'Proceedings' contain many of the most important contributions to scientific literature published in this country. The association numbers about 4,000 (1903) members, including in its list of active Fellows such well-known scientific men as Newcomb, Barker, Brush, Young, Lesley, Morse, Langley, Mendenhall, Goodale, Prescott, A. Hall, Harkness, Morley, Gibbs, Gill, Putnam, Gilbert, Woodward, and Minot. Among prominent educators who are members and have taken active interest in its work are ex-President Gilman and President Remsen of Johns Hopkins, ex-President Low of Columbia, President Schurman of Cornell, President Jordan of Stanford, President Drown of Lehigh, President Pritchett of the Massachusetts Institute of Technology, ex-President Mendenhall of Worcester Polytechnic Institute, and President Dabney of the University of Tennessee. Many names prominent in the professions and in business are found on the list of members. The yearly meetings, held in different centres, occupy a full week, and as the work is now so extensive, the different sections hold separate meetings. The 'Proceedings' are published in an annual volume, and members receive the publication 'Science.'

American Association of China, a branch of the American Asiatic Association, organized in 1898 and located in Shanghai. Membership 100; office of the secretary, Shanghai, China.

American Baptist Missionary Union, The, a missionary organization of the Baptist Church, formed in Philadelphia 18 May 1814 as "The General Missionary Convention of the Baptist Denomination in the United States for Foreign Missions." The Southern Baptists withdrew in 1845 because of differences on the slavery question, and the society assumed its present name in 1846. The headquarters were established at Boston in 1826. The sole object of the Union is the diffusion of the gospel by means of missions throughout the world. Any church which has made a contribution to the Union during the year may appoint one annual member, and one annual member for every $50 contributed above the first $50, provided that no church be entitled to more than 10 annual members. Anyone may become an annual member on payment of $10 during the preceding financial year. At every annual meeting the Union elects a president, two vice-presidents, a recording secretary, and one third of a board of managers. The board of managers consists of 75 persons, at least one third of whom shall not be ministers of the gospel. The board of managers elects an executive committee, with chairman, recording secretary, corresponding secretaries, assistant secretary, treasurer, and auditing committee. For the year ending 31 March 1902 the Union had 481 missionaries and 3,325 native helpers. Receipts were $680,518.79, appropriations $621,853.71.

American Bar Association, a society organized in 1878, with a present (1903) membership of about 1,800.

American Bible Society, The, organized in New York in 1816, to encourage the wider circulation of the Bible. Its officers are a president and 26 vice presidents. The 88th annual report for 1903 shows that the society printed and purchased in the course of the year 2,058,989 Bibles, of which 1,993,358 were issued in foreign countries. The statistician of the society also states in the report that since its organization the society has issued more than 72,000,000 Bibles. The total number of Bibles issued in the United States in the year ended 31 March 1903, was 746,423, of which New York received 225,735, Pennsylvania 135,938, and Illinois 62,878. Wyoming received only 56 copies, and Arizona 87, while the Philippine Islands stand charged with 11,774 copies. Among the "sales and grants" to foreign lands it is interesting to note that Cuba received 20,398, Africa 6,725, China 1,425 and Canada only 218.

American Board of Commissioners for Foreign Missions, The, a missionary organization of the Congregational Church, formed at Bradford, Mass., 29 June 1810, "for the purpose of devising ways and means and adopting and prosecuting measures for promoting the spread of the gospel in heathen lands." Nine commissioners were then chosen, five from Massachusetts and four from Connecticut. A charter was not obtained from the Massachusetts legislature until 20 June 1812. The first annual meeting was held at Farmington, Conn., 5 Sept. 1810. At the close of its ninth decade (1891–1900) the Board had 20 missions, 97 stations, 1,209 out-stations, 167 ordained missionaries, and a total of 544 American laborers. Native helpers numbered in all 3,483. There were 505 churches with 50,892 members, and 120 high schools and colleges. For the nine decades 2,347 missionaries had been sent out, the aggregate receipts were $32,845,372.49, and 157,658 members were received into the churches in care of the Board. The Board is a corporate body, limited to 350 active members, selected by ballot, at least one third being clergymen and one third laymen. Honorary members (who become such on payment of $100, or, if clergymen, $50) may participate in all the deliberations of the Board, but do not vote.

American Bureau of Mines, an organization incorporated under the laws of the State of New York, with headquarters in New York city. The objects of the association are to reform and encourage the mineral industry of the United States; to discountenance popular error as to the financial and industrial conditions of mineral interests; and to effect mutually beneficial relations between capitalists and men of practical science. Facts bearing upon economic and statistical science which demonstrate the importance and general utility of these branches of knowledge are stored; trustworthy informa-

tion as to sound mining and other mineral enterprises is supplied, while such as are unsubstantial or spurious are exposed; and the services of an organized and permanent faculty of experts are provided. A Museum of Metallurgy and Practical Geology for the illustration of ores and mineral products, and of mining and metallurgical constructions and appliances, and a library and reading-room have been and are important sections of the organization's equipment.

American Bureau of Shipping, a maritime association established in New York in 1867, for the purpose of collecting and disseminating information upon subjects of marine or commercial interest, of encouraging and advancing worthy and well-qualified commanders and other officers of vessels in the American merchant service, and of promoting the security of life and property on the seas.

American Chemical Society, an association established in 1876 for the support and encouragement of chemical research. Membership about 2,200.

American Civic Association, an organization formed 10 June 1904 by the consolidation of the American League for Civic Improvement and the American Park and Outdoor Association, its objects being the cultivation of higher ideals of civic life and beauty in America, the promotion of city, town, and neighborhood improvements, the preservation and development of landscape, and the advancement of outdoor art.

The Association marks a distinct epoch in American development. Stockbridge and Newton Center, two Massachusetts towns, both of which have town improvement associations more than half a century old, lay claim to the first organized effort in the United States for the preservation of natural beauties and the general improvement of the village surroundings, but the movement which the association represents first began to assume large proportions in southwestern Ohio, where a number of manufacturers, publishers, and real estate men awoke to a realization of the fact that improved surroundings made better workmen, caused men to buy homes, and led people to become interested in good literature. The beginnings of the movement were along modest lines. The term "back yard improvers," first applied to its promoters in derision, was accepted as a watchword, and the progress made has been such that now the Association represents men who have undertaken all kinds of effort for public beauty and improvement, no matter how extensive. For some years there were two bodies working in this field — The American Park and Outdoor Art Association and the American League for Civic Improvement. A consolidation was effected at a joint meeting in Saint Louis in June 1904, and the result of this merger — The American Civic Association — represents about 480 local improvement organizations. The work of the Association is divided into the following various departments: Women's Outdoor Art League; Parks; Arts and Crafts; Children's Gardens; City-making; Outdoor Art; Factory Betterment; Libraries; Public Nuisances; Public Recreation; Railroad Improvement; School Extension; Social Settlements; and the Press. An active propaganda is carried on by means of department leaflets, clipping sheets, and other methods. Membership consists of life members, sustaining members, members, and affiliated members. The head offices of the Association are in Philadelphia, Pa.

American Climatological Association, a medical organization founded in New York city in 1884 "for the study of Climatology, Hydrology, and Diseases of the Circulatory and Respiratory Organs." Candidates for membership must have contributed something to the literature of the subjects before election, this insuring a select membership, which the roll shows to be very generally distributed among the medical profession throughout the United States, with distinguished honorary and corresponding members in England, Canada, Mexico, South America, South Africa, and Australia and other parts of the world. Annual meetings have been held since the foundation, at which papers confined strictly to the objects mentioned in the constitution of the organization are read and discussed and afterward published in the 'Transactions' of the Association; 20 volumes have already appeared, and copies are sent annually to the principal libraries throughout the world. The title of some recent contributions showing the value and wide scope of this association are: 'The Advantages of Southern California in the Treatment of Tuberculosis'; 'The Climate and Waters of Hot Springs, Va.'; 'Something of the Geography of Croupous Pneumonia'; 'Recent American Contributions to the Methods of Prevention and Treatment of Pulmonary Tuberculosis'; 'Climatology as a Study in the Medical Schools'; 'The Climate of Santa Barbara, California'; 'The Climatology of Muskoka, Ontario, Canada'; 'The Climates and Diseases of Central America and Panama.' The head offices are in Philadelphia; the organization must not be confounded with a similar important and co-friendly society, "The National Association for the Study and Prevention of Tuberculosis," with headquarters in New York city.

American College. See College, The American.

American College of Heraldry and Genealogical Registry, an institution similar in character to the British "Herald's College," founded in 1860 and incorporated under the laws of the State of New York. Its objects are to gather genealogies, or family records and family history, for perpetuation to posterity; the genealogical department recording births, marriages, and deaths; the historical, obtaining the derivation and compiling the history of families; and the heraldic, ascertaining, emblazoning, depicting, and engraving family coats-of-arms, crests, mottoes, etc. See Heraldry.

American College in Rome, Italy. This pontifical college was founded 8 Dec. 1859 by Pope Pius IX. for the purpose of training young men for the Catholic priesthood in the United States of America. By a pontifical decree it was placed under the direction of the Congregation of the Propaganda, the students being obliged to attend the courses of lectures given at the University of the Propaganda. The regular course embraces two years of philosophy

and four years of theology, while preparatory classes are held for students who have not completed the college course in their own country. The American College opened with twelve students, three of whom afterward became archbishops: Michael Corrigan, of New York; Patrick Riordan, of San Francisco; and Robert Seton, titular of Heliopolis. Ruben Parsons, the historian, was also one of the original twelve. The College has trained many distinguished churchmen during its existence of less than 50 years, giving to the United States 17 bishops, among whom are the present Archbishops Farley, of New York, and Moeller, of Cincinnati. It has likewise supplied the Catholic University at Washington with its present rector, Rt. Rev. Mgr. O'Connell, and with several professors; and two of the recently appointed bishops to the Philippine Islands, Denis Dougherty, of Philadelphia, and Frederick Rooker, of Albany, are among its alumni. The College has at present about 100 students.

REV. EUGENE DONNELLY,
Graduate of the American College, Rome.

American Commerce. The growth of a nation largely depends upon the development of its economic resources, and the success of the commercial and industrial institutions is to a great extent determined by the wisdom of the laws under which they operate, as enacted by the national legislative body.

In the early days of American commerce, the domestic industries did not aggregate in value many millions of dollars, and included mainly the manufacture of textiles, lumber, furniture, wagons, harness, hats, ships, meat products, and a few others of minor importance. Against this in 1900 may be placed the following statistics: Manufacturing establishments, 640,056; capital, $9,858,205,501; proprietors and firm members, 708,623; wage-earners, average, 5,370,814; yearly wages, $2,323,055,634; miscellaneous expenses, $1,030,110,125; cost of materials used, $7,363,132,083; and value of yearly product, $13,058,562,917. In addition, farm lands and products were valued at $20,439,901,164 and $4,739,118,752, respectively; minerals and their resultants produced in 1902 were valued at $1,260,000,000; the exports in 1903 were valued at $1,420,141,679, and the imports aggregated $1,025,719,227. In 1903 the merchant marine registered 24,425 vessels of 6,087,345 tons, including canal boats and barges; there being registered 12,836 sailing vessels of 1,965,924 tons, exclusive of canal boats and barges, and 8,054 steam vessels of 3,418,088 tons. In the coasting trade the tonnage of vessels registered was 5,141,0:7, and in the foreign trade and whale fisheries, 888,776 tons. In 1904 the total mileage of railroads was 212,349, representing liabilities of $14,289,259,959 and cost of road and equipment of $11,233,311,285. During the year 715,654,951 passengers were carried and 1,275,321,607 tons of freight moved. The total traffic and other earnings were $1,998,343,310. In 1903 the national debt amounted to $925,011,637, after deducting the treasury cash balance; the government receipts ordinary were $596,396,674, and expenditures, $477,542,658; post-office receipts, $134,224,443. In 1904 the money in circulation amounted to $2,519,142,860; the bank deposits were about $10,000,000,000; the bank clearings were $102,150,313,931; and the estimated wealth of the country was over $125,000,000,000.

For details see ALASKA, COMMERCIAL; AMERICA, UNITED STATES OF; AMERICAN MANUFACTURES; AMERICAN RAILROADS; AMERICAN MERCHANT MARINE; AMERICAN MINES; BANKS AND BANKING; COMMERCE; COMMERCE, INTERSTATE; COMMERCIAL ORGANIZATIONS; EXPORTS AND IMPORTS; EXPORTS AND IMPORTS OF THE LATIN-AMERICAN COUNTRIES; FINANCE; FOREIGN TRADE; INDUSTRIAL CORPORATIONS; PHILIPPINE ISLANDS, PRODUCTS OF; TRUSTS; UNITED STATES — FOREIGN COMMERCE OF THE; INDUSTRIES OF THE; HISTORY OF THE TARIFF; RECIPROCITY; COMMERCIAL DEVELOPMENT; ECONOMIC DEVELOPMENT; and the articles on the various industries in this encyclopedia.

American Commonwealth, The, an important study of American political, social, and economic conditions by James Bryce, the eminent historian of the Holy Roman Empire. Part I. treats of the Federal government. Part II. considers the State governments (including rural and city governments), their departments, constitutions, merits, and defects. Part III. is devoted to the political machinery and the party system. Part IV. discusses public opinion,— its nature and tendencies. Part V. gives concrete illustrations of the matters in the foregoing chapters. Part VI. is concerned with non-political institutions. The work is lucidly written and as easy for the laity to comprehend as for those familiar with the practical workings of our government. The chapters dealing with the professional and social sides of American life, and especially those devoted to the American universities, have been enthusiastically received by Americans.

American Conflict, The, an account of the American Civil War and its causes, by Horace Greeley. It is a great magazine of materials for the political history of the United States with regard to slavery.

American Cousin, Our, a well-known play by the English dramatist, Tom Taylor (1858). It was very popular in the sixties, and it was while present at its representation in Ford's Theatre in Washington that President Lincoln was assassinated.

American Dialect Society, an association organized in 1888 for the study of words in American English differing in pronunciation and use from the accepted usage. Membership 300. A bulletin of 'Dialect Notes' is published yearly. Office of the secretary, Western Reserve University, Cleveland, Ohio.

American Diplomacy. It may be justly claimed that the United States, in its brief existence as a nation, has exercised a greater influence in the same period in molding international law than any other nation; and it has done much to raise the standard of diplomatic practice. From the beginning it has stood as the champion of a freer commerce, of respect for neutral and private property in war, and of the most elevated ideas of national rights and justice.

When the United States entered the family of nations, there existed a marked contrast between the state of law which controlled the rights and intercourse of nations and that which enforced the rights and duties of the individual

inhabitants of the respective nations. The civil law, which was in force in most of the countries of continental Europe and their colonies, was the accepted product of the ripened experience of many centuries of Roman jurisprudence. The common law which prevailed in England and its colonies had been brought into an established system through the careful study and practical application of successive generations of renowned jurists. But the law of nations was then in its infancy. Only one century had passed since Grotius, who has been styled the father of international law, had compiled his treatise on the 'Rights of War and Peace'; and Vattel had but recently published his 'Law of Nations,' and the principles he enumerated were far from being an accepted code. International law was still in a formative state when the United States began its career. The latter had scarcely entered upon its organized life when the wars consequent upon the French Revolution forced it to consider its rights and duties as a neutral power. It soon learned that there were no established principles which warring nations respected. In referring to its early history, a secretary of state in 1853 said to the British minister for foreign affairs: "From the breaking out of the wars of the French Revolution to the year 1812, the United States knew the law of nations only as the victim of its systematic violation by the great maritime powers of Europe."

The first effort on its part toward the maintenance of international rules of conduct was in President Washington's neutrality proclamation of 1793, which, within less than a generation, brought about a complete change on this important subject. The proclamation was a simple announcement of the neutral attitude of the government, and a warning to American citizens to observe it. But the significance of the act was in the strict impartiality of its enforcement, and the resulting legislation of Congress, which became a model for all other nations.

The power of the President to issue such a proclamation based solely upon the principles of international law, without any domestic legislation respecting offenses against neutrality, was seriously questioned, and in 1794 an act was passed defining what were offenses against neutrality and affixing penalties therefor. During the revolt of the Spanish-American colonies so much trouble was occasioned thereby to the United States authorities that the law was carefully revised in 1818, and it has since practically remained unaltered. Hall, one of the latest English authorities on international law, says: "The policy of the United States in 1793 constitutes an epoch in the development of the usages of neutrality. . . . It represented by far the most advanced existing opinions as to what the obligations [of neutrality] were. . . . In the main it is identical with the standard of conduct which is now adopted by the community of nations."

The American colonies, in assuming their independence, established a diplomatic service similar to that of the European countries and it has continued to be so maintained. But the question has often been raised in and out of Congress whether, in the existing conditions of the world, the system is necessary and its utility justifies its expense. With many in the country the diplomatic service is regarded as a purely ornamental branch of the government and its maintenance a useless expenditure of public money. But whenever the question has been made the subject of inquiry by Congress, the various Presidents and secretaries of state have given their opinions in favor of the utility and necessity of the service, and Congress has continued to authorize it; and it has come to be accepted as a permanent branch of the government.

While the United States has adopted the European system of a diplomatic and consular service, in one important particular the general practice of other nations has not been followed. The service is not made a life career, and no examination is required for admission to it, either as consul, secretary of legation, minister, or ambassador. Appointments are made of persons usually from civil life, and without any previous diplomatic experience. The two systems have their advantages. It does not necessarily follow that because a young man can pass a successful examination, he is destined to make an able minister or ambassador. The British and other governments have frequently found it necessary to appoint to the highest posts in the diplomatic service persons from other branches of the administration or from civil life. On the other hand, the system followed by the United States exposes the government to mistakes and sometimes to mortification and ridicule because of the inexperience or inaptness of its representatives. But appointments to the higher posts are generally of persons who have served and gained distinction in legislative bodies or in the professions, and although not experienced in the arts of diplomacy, they are usually able to cope with their colleagues on all subjects where great principles are involved. There is a growing sentiment, however, in the country in favor of at least placing the consular service upon a permanent basis.

Up to recent years the highest grade in the diplomatic service of the United States has been that of minister plenipotentiary, but these representatives sometimes complained that they were often humiliated and their usefulness sometimes impaired by the lower positions to which they were assigned in the diplomatic corps. The remedy suggested was to raise the rank to that of ambassador. Secretary Marcy declined to make the recommendation to Congress in 1856. A similar position was taken by Secretary Frelinghuysen in 1884, who said it would be an injustice to the ministers to give them higher rank without increasing their salaries, and that Congress would not vote the allowance commensurate with the mode of life of an ambassador. Later Secretary Bayard claimed that serious inconveniences would arise from introducing "into our simple social democracy . . . an extraordinarily foreign privileged class."

Notwithstanding these objections, in 1893 Congress authorized the appointments of ambassadors to countries whose governments would reciprocate in such grade, and ambassadors are now sent by the United States to London, Paris, Berlin, St. Petersburg, Vienna, Rome, and Mexico. Soon after the reception of ambassadors in Washington the question was raised whether they should have precedence over

the Vice-President, but it has been decided against them. The "inconveniences" anticipated by Secretary Bayard have been experienced on more than one occasion, but the innovation seems to be permanently established.

The fiction of international law that ambassadors represent the person of their sovereign in a greater degree than ministers was created at an epoch when there was a recognized distinction between empires and monarchies, and between these two grades and republics. All distinction between sovereign nations has been abolished, and they now stand on an equality, but the ambassadorial pre-eminence is still recognized, even in the American democracies.

The diplomatic dress or uniform of an American representative, although an apparently trivial matter, has occasioned considerable discussion and a varied action on the part of the government. In the early years of its history, the diplomatic representative was left without any instruction upon the subject, but when the commissioners to negotiate peace with Great Britain in 1814 went to Europe a simple uniform was adopted, and by a circular of the department of state in 1817 this uniform was prescribed for the diplomatic representatives at foreign courts. This order continued in force, with some modification during the administration of Jackson, up to the advent of Secretary Marcy, who prided himself on his attachment to republican simplicity. In 1853 he issued a circular which became famous in diplomatic annals, in which the representatives of the United States were advised to appear on public occasions "in the simple dress of an American citizen" unless such costume was objected to by the court to which the representative was accredited. The circular was much criticised, but its spirit was practically approved by Congress in the passage of an act in 1867 prohibiting officials in the diplomatic service from wearing any uniform or official costume not previously authorized by Congress. As by law only officers who have served in the army or navy are authorized to wear a uniform in the diplomatic service, the great body of the corps come under this prohibition.

From the time of Dr. Franklin, the first minister to France, American diplomatic representatives have sought to be distinguished by entire frankness and straightforward conduct. This is indicated in the instruction to John Jay when he was sent abroad on an important mission by President Washington. The secretary of state wrote: "It is the President's wish that the characteristics of an American minister should be marked on the one hand by a firmness against improper compliances, and on the other by sincerity, candor, and prudence, and by a horror of finesse and chicanery."

Much is said in disparagement of the American diplomatic representatives abroad, and it is not to be disguised that under the system of appointments some unfit and uncultured persons have been found in the service who have reflected little credit on the country. But their discreditable acts have been out-done by the misconduct of the representatives of foreign governments accredited to Washington. This misconduct has embraced flagrant violations of international law and practice, intermeddling with domestic politics, and official and social improprieties of various kinds. Within the first century after the organization of the government, a list has been created of foreign diplomats dismissed by the government of the United States, or recalled in disgrace, which embraces three British ministers, two French, two Spanish, one Russian, and one Austrian minister. No such record of dishonor can be compiled against American representatives as that made at the seat of government of the United States by the representatives of the most polished nations of the Old World.

The War of 1812, undertaken by the United States against Great Britain, was pre-eminently a struggle on the part of the former to maintain and enforce correct principles of international law. It involved the claim by Great Britain of the right of visitation of neutral vessels and the impressment of such of their crews as the visiting party saw fit; the doctrine that free ships make free goods, or the exemption of innocent neutral commerce from seizure in time of war; and the paper blockades which were sought to be enforced by the warring powers. None of these questions were settled by the terms of the treaty of peace between the United States and Great Britain. But the contention of the United States as to all of them has come to be accepted by all the nations of the world, and by none of them more heartily than by Great Britain. The right of visitation and search of vessels was a frequent subject of negotiations, but while the British government relaxed the enforcement of its alleged right after the war, its claim was not finally abandoned until 1858, when it formally accepted the contention of the United States. A strange incident in connection with this question occurred soon after that date. During the Civil War, the commander of a United States naval vessel arrested a British mail steamer, the Trent, on the high sea, visited her with an armed force, and carried away as prisoners two Confederate diplomatic agents en route to Europe. In the United States the naval commander was hailed as a hero, but in England the act was regarded as an insult to the British flag and a just cause of war. A hostile conflict was avoided by the prompt surrender of the Confederate agents and a disavowal of the act, as in direct contradiction to the attitude of the government consistently maintained from its foundation of the immunity of the vessel carrying the American flag.

The claim of the right of impressment (q.v.) was connected with the subject of naturalization and expatriation, which has been the occasion of much diplomatic correspondence and controversy on the part of the United States with European powers. From the beginning of its existence, the former has encouraged immigration; liberal laws for the naturalization of foreigners have been passed; and the right of expatriation has been maintained. In this branch of international law this attitude has had a marked effect upon the practice of nations. One of the chief causes of the War of 1812, it has been seen, was because of the impressment of seamen, naturalized citizens of British birth, taken from American vessels. The old common law doctrine was that no British subject could denationalize himself, and that he owed perpetual allegiance to the crown; but the persistent claim of the United States was finally recognized by Parliament in the nat-

uralization act of 1870. The doctrine of expatriation is now generally accepted by the nations, and the United States has succeeded in having it embodied in many of its treaties.

The subject of free ships was given much prominence through the armed neutrality during the Revolutionary War, was one of the unsettled issues of the War of 1812, and was finally recognized as a principle to be incorporated into the international code by the great powers of Europe, as embodied in the Declaration at Paris of 1856. This declaration consisted of four rules, which were, briefly stated, (1) the abolition of privateering; (2) the exemption from seizure of an enemy's goods under a neutral flag; (3) a like exemption of neutral goods under an enemy's flag; and (4) that a blockade, in order to be valid, must be effective. All of these but the first had been long advocated by the United States, and even the first had been incorporated in its treaty with Prussia of 1785. The latter was plainly in the interest of nations having a strong navy. Nevertheless, the United States was ready to accept them all as rules for the government of nations, but Secretary Marcy proposed to the great powers that they go one step further and declare that private property of belligerents at sea be exempt from capture. As private property of belligerents on land has been exempted by the rules of war, there would seem to be no sufficient reason why the same treatment should not be applied to like property at sea. President McKinley instructed the American representatives at The Hague Conference of 1899 to advocate it, but they were not successful. President Roosevelt continued to urge upon the nations this advanced measure to mitigate the ravages of war, but it has not yet been inserted in the international code.

The fourth rule of the Paris Declaration was, in effect, a formal recognition of one of the principles contended for in the War of 1812, that there can be no blockade by mere proclamation. Its application bore heavily upon the United States during the Civil War, but it consistently observed the principle by making its blockade of the southern ports effective. An effort has been made of late years to establish what is known as a pacific blockade, by which one or more States seek to bring constraint upon another State by closing its ports without a declaration of war. In the case of the blockade of Crete by the great powers of Europe in 1897, the United States declined to concede the right as applicable to its commerce; and when a similar attempt was made in 1902 of a pacific blockade of Venezuelan ports by Great Britain, Germany, and Italy, the objection of the United States to its interference with American vessels led to the abandonment of the project, and to the establishment of a real war blockade.

The subject of neutrality assumed an important phase during the War of the Rebellion, and the duties and responsibilities of a neutral state were the occasion of a heated controversy with the British government. Although the latter had incorporated in its laws the substantial provisions of the United States statutes of 1818, it dissented from the position asserted by the United States as to its duties in the practical application of its acts of Parliament and the recognized principles of international law. The construction of Confederate cruisers in British ports and the aid afforded them in such ports was held to be a failure on the part of that government to discharge its duties as a neutral power, and for these acts the United States made grave complaint and filed a large claim for pecuniary damages. After much discussion the matter was submitted to the arbitration of a tribunal, which met at Geneva. (See GENEVA TRIBUNAL.) In the treaty providing for the arbitration there were inserted three rules as to neutrality which were to govern the arbitrators in their decision. These rules were based upon the American statute and mainly followed the contention of the United States. The result was a decision in favor of the latter, with a large award in damages. The two governments had agreed in the treaty that they would submit the rules to the other maritime powers for their acceptance, but this was never done, chiefly because of the extreme construction placed upon some of their clauses in the opinions of the neutral arbitrators. The general consensus of publicists is that these rules are a correct statement of existing international law.

One of the conspicuous features of the relations of the United States with foreign nations is its readiness to accept arbitration for the settlement of questions that do not prove susceptible of adjustment by diplomatic methods. It has been one of the foremost of the nations in advocating this method of arranging international complications, and in preserving peace by means of treaties of arbitration. The first treaty negotiated after the organization of the government under the Constitution — the Jay Treaty (q.v.) of 1794 — was made with Great Britain to avert war which was then imminent. It contained provisions for the adjustment of three of the most irritating of the questions in controversy by a reference to arbitration, and three separate commissions were created for that purpose. The year following, the second treaty negotiated by the new government, that with Spain of 1795, also contained a provision for arbitration. The country was not so fortunate in its second controversy with Great Britain. The questions at issue were of such grave character that it did not seem possible at that day to settle them by any other method than a resort to war; but by the treaty of peace of 1814 four boards of arbitration were created to settle boundary questions. These all related to the frontier with Canada, which ever since the independence had been a source of almost constant discussion, often of angry controversy, and more than once has brought the countries to the brink of war. But in every instance when the usual method of diplomacy failed, arbitration has been resorted to with success.

During the two generations which followed the War of 1812 all questions of controversy with foreign powers, with one exception, have been settled by peaceful methods. In that period the United States created many courts and commissions of arbitration. The most of these have been with Great Britain, but more than 20 of them have been with other nations of Europe and America. The controversy growing out of the manner in which the British government enforced the neutrality laws during the Civil War, for a time threatened the peaceful relations of the two countries. When the offer of

the United States to adjust the question by arbitration was made, the British government in the first instance assumed the position that its national honor was involved, and that that could not be submitted to arbitration. But better counsels prevailed, and the Tribunal of Geneva was created to adjust the controversy. It was the most important arbitration in which the United States ever engaged, and was one of the most august and imposing ever held in the world. It involved questions of supreme importance and pecuniary claims of great magnitude; but its special significance was in the spectacle of two great nations being able to compose weighty matters, which had awakened the passions of their people to a high state of bitterness, by an appeal to reason and the arbitrament of friendly powers in place of war.

Next in importance for the United States to the Geneva arbitration was that relating to the protection of fur seals in Bering Sea, held in Paris in 1893. The decision of the tribunal was against the contention of the United States, and as a result it had to pay about half a million of dollars in damages and sustained a heavy loss in its annual income from the seal islands. Disappointment was felt over the result, but the mature judgment of the country is that it was a wiser settlement of the questions at issue than to push them to the extreme of war.

One feature of the many arbitrations in which the country has engaged is worthy of special notice. A spirit of equity and fair dealing has always marked the conduct of the government in cases where any suspicion of fraud or exaggerated damages has attached to arbitral decisions. The commissions with Venezuela, Haiti, Mexico, and other countries might be cited in illustration. They show that, though the government is sometimes misled by designing claimants or by the unwise action of its diplomatic agents, it has not hesitated when fully possessed of the facts to undo any injuries inflicted upon friendly powers by means of international commissions, and that fraud, once exposed, cannot reap the benefit of its iniquity under the cover of the finality of an award.

The Alaskan Boundary Tribunal of 1903 is an instance of the settlement of a question not possible of adjustment by diplomacy and not deemed appropriate for reference to arbitration. A court was constituted, composed of three members from each country, and they were empowered to judicially settle the questions submitted to them. The danger feared was that there would be an equal division of the court, but in this case the matter was settled by an award rendered by a majority of the members which has been accepted by both governments.

This brief review shows that in its short career the United States has had an important part in molding the code of international law. The chief actors in the work done by this country have been the secretaries of state and its diplomatic representatives abroad. But they have had worthy coadjutors in giving this code shape and permanence. The exposition of the law of nations, as set forth in the decisions of the Supreme Court of the United States, has had a great influence in molding that law, and its opinions are recognized as of the highest authority by foreign publicists. Among authors in this department of law none carry greater weight throughout the world than Story, Kent, Wheaton, Halleck, Woolsey, Wharton, and other American writers. When the services are recalled of these diplomatic, judicial, and scholastic representatives of the United States, it is just to say that no body of men in any country have done as much to improve and enlarge the principles of international law, or have exercised a more salutary influence on the affairs of the globe. See also DIPLOMACY; INTERNATIONAL LAW; UNITED STATES — THE DIPLOMACY OF.

American Entomological Society, an association established in 1859 for scientific investigation of insect life. Membership 125. Office of the secretary, Philadelphia, Pa.

American Farm Implements. The production of food and fibre absorbs about three fourths of the labor of the male workers of the world. In the United States, during the early decades of the 19th century, about 80 per cent of the male workers of the nation were employed on the farm. During the past century, however, farm implements and machines have come into use which have so increased the efficiency of labor that about 35 per cent of the male workers of the United States produce the food and fibre of the nation, and furnish an enormous surplus which is exported to other countries. Nowhere else in the history of human industry can so striking an illustration be found of the influence of inventions upon the welfare of mankind. From time immemorial, until the 19th century, agriculture was carried on by hand labor. Horses or oxen were used for plowing and harrowing, but the labor of seeding, planting, cultivating and harvesting the crops was performed by the exertion of human muscle. Wheat was sown broadcast by hand, reaped by hand with a sickle, and separated from the straw and chaff by hand labor. Corn was planted by hand with a hoe, and cultivated with a hoe, and was gathered and shelled by hand. Grass was cut with a scythe and raked and handled with hand rakes and forks. Production was so limited by these primitive methods that people who wished, like the pioneers of America, to enjoy an abundance of food and other simple comforts of life, were compelled, of necessity, to live on the farm, where they could be assured, by their own efforts, of a proper supply. The farmer was unable to produce a surplus that would feed a large urban population. Manufacturing industries were not only limited by the lack of food to sustain cities, but were also limited by the lack of a market for factory products, for an agricultural country which could not produce a surplus for sale was unable to buy the products of urban industries.

The farmer of the North lived in a log cabin, wore homespun, and sent his children to a log schoolhouse. The only section where agriculture was conducted on a commercial basis was the South, where the planters profited by slave labor.

It is generally assumed that the railroads brought prosperity to the people, by affording the pioneer farmer the means to market his products. Government statistics throw an interesting light on this subject. Railroad construction in the United States began in 1828, and continued at the average rate of about 300 miles per year until 1846. For a few years the commerce of the country made substantial growth, but the period from 1837 to 1846 was one of great depression, which the railroads were unable to relieve. Bank resources, which showed but little loss in the year following the panic of 1837, shrunk to a remarkable degree from 1840 to 1843, the only period in the past seventy years when there was a serious loss in bank capital. The railroads did not stimulate the production of wheat during this period, for a large amount was imported from Europe in 1837, and the census reports show that the crop of 1839 amounted to only 4.97 bushels per capita, which was not enough to supply the people with wheaten bread. From 1800 to 1846 exports of flour amounted to an average of about a million barrels per year, and showed no material increase, while exports of wheat were actually less from 1830 to 1840 than in the first decade of the century.

If the first 15 years of the railroad be compared with the first 15 years of the reaper, a most remarkable contrast is found. The reaper was first placed on the market successfully for the harvest of 1845. In 1847 exports of wheat and flour leaped to $32,178,161, about five times the average of the preceding forty years, and grew rapidly from 1850 to 1860. The wheat crop, which had not increased as rapidly as population from 1839 to 1849, gained more than 70 per cent from 1849 to 1859, the largest increase that is shown in any census decade. In 1880, after 35 years of the reaper, exports of wheat and flour amounted, in one year, to $225,879,502. Prior to 1850 corn was used extensively for bread, because the supply of wheat was deficient, but since 1850 the United States has produced for exportation a surplus of about five billions of bushels of wheat. Railroad construction, which had averaged only 300 miles per year prior to the introduction of the reaper, made remarkable gains in 1847 and 1849, and progressed at the rate of about 2,000 miles per year from 1850 to 1860.

A broad examination of the subject shows that railroad construction and agricultural inventions have gone hand in hand in the development of agriculture in America. Railroads could not be operated profitably in the agricultural States without the traffic that is produced for them by labor-saving inventions on the farm; and, on the other hand, there would be little demand for these inventions if the railroads were not available to market large commercial crops. The farmer of a century ago, without these inventions and the railroads, was a peasant who toiled with his hands to produce a living for his family. The farmer of to-day is a machine operator who rides on a comfortable spring seat and uses labor-saving inventions to produce commercial crops. American inventions have made agriculture a commercial business in which a man, without employing help, can support a family comfortably and produce wealth. American farmers enjoy a greater average of comfort and wealth than any other class of people, of equal numbers, in the world.

The reaper, invented in 1831 by Cyrus H. McCormick (q.v.), of Rockbridge County, Va., and patented by him in 1834, was the first important step in developing the implements and machines of modern agriculture. Wheat must be harvested within a few days after it ripens, or the crop will be damaged or destroyed by the weather. When wheat was cut with sickles a man could only harvest three to five acres, in an average season, and this limitation accounts for the small production of wheat prior to the introduction of the reaper, which broadened production by enabling a given number of men to harvest a larger acreage. The McCormick reaper of 1831 was used successfully for several seasons, but the facilities for manufacturing a complex machine like a reaper were so limited at that time that it was not until 1845 that the invention was made a commercial success. The McCormick reaper embodied the foundation principles of modern harvesting machines. The machine was balanced on two wheels, like a cart, one, the master wheel, being geared to furnish power for the mechanism. The platform extended between the two wheels, and on its front edge was the cutting mechanism, a reciprocating knife, operated by a crank, and moving over fixed fingers. The most notable feature of the McCormick reaper was the divider and the revolving reel, which separated the grain to be cut from the standing grain, and laid the flowing swath, by a positive delivery, on the platform, so that the straws would lie in parallel order and make a compact sheaf when bound. It was the reel and the divider that made the McCormick invention a commercial success, because grain in all the ordinary conditions of harvest could be handled successfully. The greatest problem in reaping is not to cut the grain, but to make it lie down peaceably on the platform after it is cut, especially since a large proportion of the wheat crop becomes more or less lodged and blown down by winds and rains before it is cut. A score or more of inventors had anticipated McCormick in efforts to design or construct reapers, but while some of them had machines that would cut the grain, they had no practical devices for delivering it in gavels so it could be bound into sheaves. Robert McCormick, the father of Cyrus H., made a machine in 1816 with a revolving scythe, and in the papers of Thomas Jefferson is found a copy of a letter which he wrote to an inventor, commenting on the design of a machine of the same character. None of these numerous designs of American and English inventors proved practical, and it remained for Cyrus H. McCormick, who inherited the problem from his father, to bring together the four essential elements of modern harvesters: the reel, the divider, the reciprocating knife and the platform. A few years after the reaper was made a commercial success, the self-raking attachment took the place of the man who had raked off the gavels by hand. In 1858 C. W. and W. W. Marsh, of Illinois, patented a notable improvement which

THE OLD WAY OF CUTTING AND BINDING GRAIN.

THE NEW WAY—THE GIANT REAPING AND BINDING MACHINE.

led the way to the modern binder. In their machine endless toothed belts carried the grain from the platform over the master wheel, and deposited it in a receptacle. Two men stood on a footboard or platform outside the master wheel, and, taking gavels alternately from the receptacle, bound the sheaves on tables attached to the machine. In 1873 the first automatic sheaf binding harvester, the invention of Sylvanus D. Locke, was placed on the market, and a year or two later other machines of the same type, using wire to bind the sheaves, were successfully introduced. About the time the wire binder had become settled on the market, a new invention, the twine binding mechanism, upset all the calculations of harvesting machine manufacturers, as the farmers preferred twine to wire, which became scattered over the fields from the threshed straw and proved a nuisance. The foundation patents on the twine binding mechanism were issued in 1875 to Marquis L. Gorham, of Rockford, Ill. After he had tested his invention in the field, but before he had perfected it for the market, death cut short his career, and it remained for John F. Appleby, of Beloit, Wis., to complete the development of the twine binder. More than twenty manufacturers took licenses under the Gorham and Appleby patents, and twine binders were placed on the market in 1880, since which time the business has grown to large proportions. Fully a million binders are in use on American farms, and a large export business has grown up. Through the use of American harvesting machines, Russia, the Argentine and Australia have become large exporters of wheat, and single cargoes of American machines, which are shipped to European countries, contain more machines than the entire output of any European manufacturer in this line.

In any humid climate it is necessary to bind the wheat in sheaves and let the straw and grain dry out in the shock before threshing, but in many of the western States the harvest season is dry, so that a more economical method can be followed. In western Kansas and Nebraska, and other States farther west, headers are used successfully. The header is a wide cut machine, usually taking twice as wide a swath as a binder, and cutting just below the heads, which are elevated into a wagon and hauled to stacks or ricks to await the thresher. In California, Oregon and Washington the combined harvester carries a threshing attachment, which is operated by the traction wheel, so that a wide swath is cut and threshed and delivered in bags as the machine is drawn across the field by horses or a traction engine. The combined harvester, however, can only be used where the harvest season is very dry, and where the straw grows stiff, so that the wheat can stand until it is dry enough to thresh.

The mowing machine, the corn planter and the two-horse corn cultivator, distinctively American inventions, have served the same purpose in promoting the production of meat in the United States as the reaper in promoting wheat growing. Farmers were not able to produce live stock and dairy products on a large commercial scale until they had been provided with labor-saving inventions for the cheap production of hay and corn. Obed Hussey was the inventor of the foundation features of the mowing machine, but his work was not completed until the hinged or floating bar had been invented by Lewis Miller. Hussey's first patent was taken out in 1833 on a reaper which he had made near Cincinnati, Ohio, that year. Owing to the fact that he obtained his patent on an improvement in reaping machines, and the further fact that it was issued a few months before the first McCormick patent on the reaper, many writers have given to Hussey the credit for the invention of the reaper. The two machines, however, were essentially different. The Hussey machine had no reel or divider, and while the cutting mechanism worked well, it was never a commercial success as a reaper, because it could only be used when the wheat stood up straight. The McCormick reaper was balanced on two wheels, like all modern harvesters. The Hussey machine had four wheels, two in the same position as the wheels of a modern mower, and besides these a grain wheel, at the grainward end of the platform, and a castor wheel at the rear. Dropping the two superfluous wheels and the platform, the machine embodied the foundation features of a mower. In 1847 Hussey patented, as an improvement on his machine, the open back guard or finger, which proved a vital feature of successful mowing machines. The upper part of the finger, through which the knife moved, was cut away at the rear, so that grass and trash which were drawn into the slot by the knife were swept away to the rear by the pressure of the grass passing over the bar. Curiously enough, Hussey never made any serious effort to develop his machine as a mower. He believed all his life that he was the inventor of the reaper, and for twenty-five years he worked incessantly but unsuccessfully to establish his machine on the market as a reaper. The only financial reward that he ever reaped, however, was in 1858, near the close of his life, when a syndicate of mowing machine manufacturers, who were operating under license from him, paid him $200,000 for his patents. A few years before, he had made application to the Court of Claims at Washington for a financial reward from Congress for his inventions, stating that he was not worth at that time more than $500 above his liabilities. He worked all his life, the greater part of the time in poverty, in efforts to establish his invention as a reaper, and did not know that his patents covered the foundation features of the mower, a machine second only to the reaper in its importance to agriculture. It remained for practical licensees under his patents to recognize their value and pay him for them a price far in excess of the reward that he had hoped to obtain from Congress. In 1856 and 1858 the most important patents on the hinged or floating bar were issued to Lewis Miller, of Canton, Ohio, who was identified with the leading firm in the syndicate that bought the Hussey patents. Miller's improvement allowed the bar to float freely over the ground, and to rise or fall at either end so as to conform with the inequalities of the surface.

While the mower was the most important hay-making invention, because it enabled the farmer to harvest a larger acreage of hay, many other inventions have been of vast service in promoting the cheap production of forage. Steel sulky rakes made short work of gathering the hay into windrows, and the hay tedder, which is used after the mower to shake up the hay so it

will dry quickly, makes it possible to put the hay in the barn or stack within a few hours after it is cut. Hay loaders are now used extensively, taking the hay from the swath or windrow and loading it on the wagon. Barns are equipped with hay carriers and forks, operated by a horse, which take the hay from the wagon and save the hard labor of pitching it by hand. The same equipment is also used for stacking in the field. On western ranches, very wide sweep rakes are used to gather the hay and drag it up to the stack, where a stacker, operated by a horse, elevates it from the ground to the stack.

Next to harvesting machines, the threshing machine is undoubtedly the most important feature of the mechanical equipment of modern agriculture. Early in the 19th century the "ground hog" thresher came into use. This was a simple machine, operated by a tread power, threshing with a spiked cylinder which revolved over a spiked concave. It had no mechanism for cleaning the grain. The straw was forked or raked away from the tail of the machine by hand, and the pile of chaff and grain was afterwards cleaned by running it through a hand fanning mill. These machines, however, found but little use so long as the crop was limited to the amount that a man could reap with a sickle, as the farmer could store his small crop in the barn and thresh it out in winter, either with horses on the barn floor, or with the flail, a long, jointed club. The first English separator, combining a threshing cylinder with fanning and screening devices, was made in 1800, but this was a stationary machine, like many other inventions of that period, designed to be set up in a mill, to which the grain must be brought. Hiram A. and John A. Pitts, of Winthrop, Maine, were the inventors of the first portable threshing machine with cleaning devices. They were engaged in making horse powers for operating "ground hog" threshers, and in 1837 they patented a machine which combined the threshing cylinder with an endless belt and beaters, which separated the grain from the straw and chaff. George Westinghouse (q.v.), the father of the inventor of the air brake, began making threshing machines at Fonda, N. Y., about 1840, later removing to Schenectady, and he patented a number of practical improvements in separating and cleaning devices. After 1850, when farmers began to raise wheat for market, a large number of inventors and manufacturers of threshing machines entered the field, and machines of the endless apron or grain belt type soon came into general use. Soon after the Civil War, however, these machines gave way to the "vibrator" type of separator. The endless apron or grain belt, in spite of all the beaters and shaking attachments that were used with it, allowed a little grain to go through with the straw and be wasted. Cyrus Roberts, of Belleville, Ill., patented in 1852 and 1856 the chief features of the modern separating mechanism, which consists of a series of vibrating rakes over which the straw passes from the cylinder. The most notable improvement of recent years is the "wind stacker." The tail of the machine is closed, and the straw is blown by a revolving fan through a large steel pipe. This invention saves the labor of all the men who were formerly needed on the straw stack. Automatic band cutting and feeding attachments, and automatic grain weighers, have also come into general use. The horse power was succeeded in the decade following the Civil War by the portable engine, and this in turn by the traction engine, which, for countries where coal is scarce, is fitted to burn straw.

The grain drill was one of the latest of modern implements to come into general use, as the farmers found it more economical, until well past the middle of the century, to sow their wheat broadcast by hand. English inventors began patenting grain drills in the 18th century, and many American patents were issued prior to 1850, but the grain drill did not become a practical implement until it was provided with a force feed, which would regulate exactly the amount sown. The first patent on a practical force feed was issued in 1851 to Foster, Jessup & Brown, of Palmyra, N. Y.; but it was not until farmers began sowing commercial fertilizers that drills replaced broadcast seeding in the East. In the West, the "hoe" or pointed tube of the early types of grain drills could not be used successfully in prairie soil, and the farmers sowed their grain by hand, or used simple broadcast seeders, until the drill manufacturers had borrowed the shoe from the corn planter. In late years disc drills have become popular.

The first patent on a practical corn planter was issued in 1853 to George W. Brown, of Illinois. This implement was not, as many writers have supposed, an adaptation of the grain drill. The function of the grain drill is to spread the seed as much as possible, so the crop will cover the ground and prevent the growth of weeds. Corn, however, does not thrive unless each hill has at least a square yard of clear, cultivated soil around it, and hence corn is planted in hills, and the hills are placed in check, so they can be cultivated both ways. The Brown invention planted two rows. It was operated by two men, or a man and a boy, one of whom drove while the other sat in front and operated the dropping lever. It was customary, before the introduction of the check rower, to mark the field by driving across it with a sled which had two or more runners, making marks at the proper distance apart for the hills. The planter was then driven at right angles across the marks, and the operator of the dropping lever would aim to drop the hills even with the marks, so they would be in alignment across the field, as well as in the rows following the planter. The check rower, which was invented and introduced by George D. Haworth, of Illinois, as an improvement on the planter, operated the dropping mechanism automatically. A wire is stretched across the field, anchored at each end, and as the planter is driven forward the wire draws through it, and buttons or links at suitable intervals operate the dropping device. The Haworths were the practical inventors of this device, and placed it on the market, but did not obtain a clear patent on it, as, technically, it had been anticipated by a prior inventor, whose patent was assigned to them and reissued. The most ingenious and original feature of the George W. Brown patents on the corn planter was the planting shoe, which was shaped like a scimeter, so it would cut through or rise over any trash on the surface of the field. The seed dropped through a channel in the heel of the shoe, and was covered by a wheel which followed.

A MODERN STEAM PLOW THAT TURNS SEVEN FURROWS AT ONE TIME.

So many inventors have contributed useful features to the two-horse straddle-row cultivator that it would be difficult to name any one who is entitled to pre-eminent credit. Cultivators are made in a greater variety of forms and styles than any other implement in extensive use, but the basic idea of all modern cultivators is to utilize two horses and straddle the row. Two wheels, with an arched axle, support the frame work and the seat for the operator. The cultivating shovels or points are attached to two gangs or frames, one on each side of the row, which swing freely and are held in the proper position by the operator, by means of stirrups in which he holds his feet. Walking wheeled cultivators are still used to some extent, but the prevailing demand is for riding implements.

Harvesting the corn crop is a problem that has engaged the attention of American inventors since 1850, but it was not until 1895 that a practical corn binder was placed on the market. This machine was patented in 1892 by A. S. Peck, of Illinois, but did not prove practical until many improvements had been made by inventors of the McCormick experimental staff. A binding attachment, much like the mechanism of a grain binder, stands in a vertical position in the machine, and the corn is carried into it by gathering chains while the machine travels forward astride the row. A later type of this machine is the corn shocker, which holds the corn erect in a frame, without binding it in bundles, until a shock is collected, when the frame and shock are raised by a crane on the machine and swung around to the ground, the shock, meantime, being tied at the top by the operator. The latest successful type of machine for harvesting corn is the corn picker, which travels along the row in the field and picks and husks the ears without cutting the stalks. The portable corn husker and fodder shredder, which is operated like a threshing machine, has also proved a successful invention, and many thousands of machines of this type are now in use, especially in the dairy States, where the farmers want to save the fodder and shred it for feeding. Power corn shellers have been in use since 1860, and are indispensable wherever corn is grown for shipment to market. The first successful machine of this type was invented by Augustus Adams, of Sandwich, Ill.

For the preparation of the soil a multitude of implements are used. The subject of Plows has been considered in a separate article. Harrows are made in many forms, including the disc harrow, which is used extensively in place of the plow, to prepare stubble land for seeding. The steel disc has made its appearance in grain drills, and in planters, and has even endeavored to supplant the moldboard in the plow. Potato planters, spraying implements and digging machines have placed the potato crop on a commercial basis. Cotton planters are used successfully, but disappointment has been the only reward of inventors who have sought to devise a cotton harvester. The greatest service which the inventor could render to the cotton grower was the invention of the cotton gin by Eli Whitney (q.v.). While the gin is not strictly speaking a farm implement, since it is not used on the farm, it made a great commercial crop of an obscure plant that had been of little or no value to the farmer. R. L. ARDREY,

Chicago, Ill.

American Federation of Labor, a national organization of American trade-unions, in which the rights of the constituent units are preserved intact. As in the Federal government, all powers not expressly granted in the written constitution are reserved to the subordinate bodies: but still further, as in the Articles of Confederation, it has not power of compulsion (except to suspend or expel a union), and any union can override its decisions as far as its own action goes. To this is due its steady growth and harmony. What every union fears most of all is being controlled in matters pertaining to its own trade by persons outside that trade; and a minority regularly coerced on its own ground will eventually secede.

It originated in 1881. Its predecessors had been the National Labor Union, 1866–72, which ended its career by entering politics and nominating a candidate (David Davis) for the Presidency; and a number of sectional orders, of which the chief was the Knights of Labor (1869). The latter were generally hostile to trade-unions, holding them based on "false and selfish principles of temporary advantage, to the sacrifice of the general interests" of labor, and the Knights attempted to break down trade barriers in workmen's action by organizing local assemblies of miscellaneous laborers. This antagonized those who believed that only members of a given craft had a right or the proper knowledge to direct its action; and on 2 Aug. 1881 representatives from trade-unions, the Amalgamated Labor Union (a split from the Knights of Labor) and the Knights of Industry, both secret orders, held a conference at Terre Haute, Ind., ostensibly to establish a national labor congress, but in reality (as stated) to form a new order to supplant the Knights of Labor. This was defeated, and the conference issued a call for a convention at Pittsburg in November, where the Federation of Organized Trades and Labor Unions of the United States and Canada was constituted. On 8 Dec. 1886 this fused with a separate trade-union congress, and changed its name to the American Federation of Labor; and in 1889 acknowledged the continuity of existence by dating its proceedings to 1881. Its membership is of local unions, central unions of cities, State federations, national and international trade-unions. As a local union may thus belong to three different superior bodies, with a possible conflict of jurisdictions, the Federation takes charge of these mutual relations. It recognized the national and international unions as having supreme jurisdiction, but it approves and urges State and central bodies as helpers in gaining the common objects.

These objects, as stated in its constitution, are: (1) "The encouragement and formation of local trade and labor unions, and the closer federation and combination of such bodies, to secure legislation in the interest of the working masses." (2) "The establishment of national and international trade-unions, based upon a strict recognition of the autonomy of each trade," etc. (3) "An American Federation of all national and international trade-unions, to aid and assist each other," and "the sale of union-label goods, and to secure national legislation in the

interest of the working people, and influence public opinion by peaceful and legal methods in favor of organized labor." (4) "To aid and encourage the labor press of America."

Its executive organization at first was a secretary and a legislative committee, and it announced that it would have no salaried officials; but for efficient working it has been compelled to modify this rule. It has a salaried president and secretary, a treasurer, and six vice-presidents, who together form the executive council, which meets quarterly. The president for many years has been Samuel Gompers.

The funds are derived from a per capita tax of 6 cents per year from each member of an affiliated trade-union, and $10 each from central unions and State federations. Until 1887 it could not grant money in aid of strikes; but in that year a revised constitution gave the executive council the right to call on the unions for financial aid to such strikes as it approved. This voluntary aid was insufficient, and in 1889 another amendment permitted it to levy a compulsory tax of 2 cents a week on each member of an affiliated union, for not over five weeks, in aid of strikes or lock-outs.

The policy of the Federation is fixed in open conventions held in a different city in November of each year. The affiliated organizations are entitled to but one delegate until their membership reaches 4,000, two delegates up to 8,000, three delegates up to 16,000, four delegates up to 32,000, and so on. Thus, for instance, the largest affiliated organization, the United Mine Workers of America — having a membership of fully 225,000 — will send seven delegates, and is entitled to no more.

The chief rival of the American Federation has been the Knights of Labor; but it has practically supplanted that from the superior rationality of its basis. The Knights admitted anyone to membership except lawyers, bankers and saloon-keepers; the Federation confines membership to workingmen, not admitting even farmers who are employers of labor on their farms. The Knights were a centralized society based on lodges established by the central union; the Federation is based on its unions' individuality. But chief of all, the Knights assumed that organizations of all classes of workers in one union in each locality would bring about the best results, while the Federation realized the organization of each trade in its particular union and the affiliation of all unions in a comprehensive federation was sure to strengthen each and bring advantage to all. The Knights confounded all distinctions and potentially overruled each trade by the vote of outsiders. By recognizing the common-sense principle that each interest can manage its own affairs best, the Federation has grown till, on 1 Oct. 1903, it had in affiliation national and international unions, 112; State federations, 29; central unions, 529; and local unions, 1,725. The total membership of unions is estimated at about 1,750,000, of whom more than half have joined since 1897. It does not contain all the trade-unions, a considerable section still remaining outside, as the great railroad federation of five unions, and the Bricklayers' Union; but it contains the United Mine Workers of America (its largest body), the International Typographical Union of North America, the Brotherhood of Carpenters and Joiners, the Cigar Makers' International Union, etc.

Its activity in securing favorable and defeating unfavorable legislation for laborers has been very great and very successful. These are too many to detail; but it may be said that its first convention of 1881 demanded a national eight-hour day for government employees, and exclusion of Chinese and contract laborers; and all these were granted by 1886. It also secured the establishment by law of Labor Day. Since then it has steadily favored shorter hours, non-employment of children, better sanitary conditions, regulation of convict employment, abolition of "government by injunction," etc.; and in 1893 pronounced decisively for free coinage. It began in 1894 the publication of 'The American Federationist,' an official monthly magazine. Consult: Aldrich, 'American Federation of Labor,' Vol. III. of Economic Studies (1898); Gompers, 'The Labor Movement'; McGuire, 'The American Federation of Labor'; and annual reports of the Federation. SAMUEL GOMPERS,

President American Federation of Labor.

American Folk-lore Society, an association founded in 1888 for the collection and publication of the folk-lore of North America. Membership 410. Office of the president, Field Columbian Museum, Chicago, Ill.

American Forestry Association, a society organized in 1882 and incorporated 1897. It aims to promote a business-like and conservative treatment of the forest resources of this continent; the advancement of educational, legislative, and other measures tending toward this end; the diffusion of knowledge regarding the conservation, management, and renewal of forests, the proper utilization of their products, methods of reforestation of waste lands, the planting of trees for ornament, and cognate subjects of arboriculture. Membership 2,000. Its official organ is 'Forestry and Irrigation.' Office of secretary, Washington, D. C.

American Geographical Society, an association established in 1852 and aiming to encourage geographical exploration and discovery; to investigate and disseminate new geographical information by discussion, lectures, and publications; to establish in the chief maritime city of the country, for the benefit of commerce, navigation, and the great industrial and material interests of the United States, a place where the means will be afforded of obtaining accurate information for public use of every part of the globe. It has a geographical library of 30,000 volumes and a large and very valuable collection of maps, charts, and atlases relating to every part of the world. It publishes a 'Bulletin,' and co-operates and interchanges information with 200 domestic and foreign geographical and other scientific societies. Membership 1,200. Office, 15 West 81st Street, New York.

American Historical Association, a society organized in 1884 and incorporated by an act of Congress in 1889 for the encouragement of historical research. Membership 1,100.

American Indians. See INDIANS, AMERICAN.

American Institute of Architects, an association organized in 1857 for the advancement of the art or profession of architecture. It has published its 'Proceedings' annually since 1867. Its permanent headquarters are in its own building, the "Octagon," Washington D. C. Membership 800.

PLOWING A FURROW SIX FEET WIDE WITH A TRACTION ENGINE.

American Institute of the City of New York, an organization founded in 1828 for the promotion, by exhibitions and fairs, of agricultural, commercial, manufacturing, and artistic interests throughout the Union. It is now divided into five sections: The Farmers' Club, the Henry Electrical Society, the Horticultural Section, the Photographic Section, and the Polytechnic Section. It has a scientific library of 15,000 volumes.

American Institute of Electrical Engineers, a society established in 1884 for the advancement of electrical engineering. It publishes volumes of its 'Transactions.' Membership 1,600.

American Institute of Homœopathy, a society organized in 1844. Membership 2,000.

American Institute of Mining Engineers, an organization founded in 1871 to promote the arts and sciences connected with the economical production of the useful minerals and metals, and the welfare of those employed in these industries, by means of meetings for social intercourse and the reading and discussion of professional papers, and to circulate, by means of publications among its members and associates, the information thus obtained. Membership 3,500.

American Ipecac. See GILLENIA.

American-Irish Historical Society, founded in Boston, Mass., 20 Jan. 1897, to make better known the Irish chapter in American history. The organization draws no creed lines and is non-political. It has published a number of books and pamphlets along its chosen line of work. The society is national in its scope, and has members throughout the country. The organization holds its annual gathering in New York city, and publishes yearly a bound volume called the 'Journal' of the society. The membership is about 1,000. In addition to the national officers, there is a vice-president for each State.

Americanisms, in language, are words or phrases peculiar to the English speech of the United States or of British America. They may be (1) forms originating in America; or (2) forms that have emigrated from Britain and that have continued in use here while they are obsolete there; or (3) that have undergone here an essential change of signification. Examples of words originating here or at least first introduced here into the vocabulary of the English language are Buncombe, Caucus, Gerrymander; of words here in current use but now antiquated in England we have Fall (the season), Wilt (verb), Whittle; and of words with changed signification we have Corn (maize), Partridge (quail or ruffed grouse), Store (in England shop). These three processes of new word coinage, of survival of meanings in one province of the language which in another province have become obsolete, and of essential change of signification, are inherent in all languages, and can be traced in a comparison of two counties as clearly as in two countries. Americanism expresses the character of English speech in America: it does not imply any inferiority of American English to British English; nor is American English subject to correction by the laws that British English prescribes for itself: Americanism and Briticism in speech are mutually on an equal footing; unlike Gallicisms, Germanisms, or even Scotticisms, Americanisms are not aliens in English, but natives. Among the Americanisms to to be noted in what follows are many words or phrases which belong to the vocabulary and phraseology of slang, and are universally regarded as vulgarisms and solecisms and vicious growths of the vernacular speech of America; as such they are "Americanisms," but they are no more part of legitimate American speech than is costermongers' English part of the English language of the home country.

In the front rank of Americanisms must be classed those which are most racy of the soil and that could not have been evolved in any social or physical environment other than was and is presented in this new world. The first settlers had to clear the boundless forest which covered the land, and constantly to guard their lives and their possessions against the forays of the savages: they went always armed to their day's work. Such words and phrases as Going on the war path, Digging up the hatchet, Burying the hatchet, Scalping, Tomahawking, recall the hero-tales of American pioneering; and from the same period come Shanty, Blazing out, Clearing, Backwoods (in Canada, "the Bush"). They "took to the woods" or "to the timber" for refuge at the approach of the redskins in overwhelming force. In the sparsely peopled settlements the necessity for neighborly help in gathering in the harvest or in erecting a log cabin or in providing comforts for the winter led to the custom of the Raising-bee or Building-bee, the Quilting-bee, the Husking-bee: the origin of the word Bee in this sense is unknown; the custom itself survives in rural districts, and a few years ago a new sort of Bee — the Spelling-bee had great vogue; and that was followed by the Definition-bee; these "bees" met with much popular favor in England. Logrolling is another example of co-operation among backwoodsmen, when neighbors associate to collect each other's logs for the winter fires. Logrolling came early into use as a term of the art of practical politics to signify the co-operation of members of a legislative body to promote one another's schemes. Literary Logrolling is when authors combine to create a market for each other's productions by mutual puffery. Salt springs to which the big game used to resort were Salt Licks; the spaces between stretches of water over which the pioneers had to carry their canoes were Portages. As settlers began to seek homes in the West on government lands, the distribution of the public domain became a business of vast proportions and "a Land-Office business" became a superlative term of comparison. A Section of land is a square mile or 640 acres; a very usual subdivision is the Quarter section, 160 acres. In the nearer West, as in the East, bodies of land were Farms; in the farther West, Ranches; in the South, Plantations. The verb to Deed is a pure Americanism: the phrase "To convey by deed" was too slow. A settler who acquired land from the government "blazed out" his grant by cutting with his axe marks on the bark of trees: the word is from the French *blason*, a term of heraldry. A Lot of ground is any distinct portion of land, and in towns and cities is a piece of ground with a definite frontage, usually 25 feet. The use of the word lot in the

sense of a parcel of land seems to have originated with the Puritans in Massachusetts: for this they had scriptural authority, Joshua xv. To go Across lots is to take the shortest route; but to make a Bee line toward a place is to haste to it in a straight line. Immigrant is an Americanism, and it is the accurately fit word to signify one who comes to a country as a settler. Tenderfoot, a most expressive American slang word to designate the newcomer into a newly opened gold or silver mining district, is current coin no less in Australia than in the Rocky Mountains. In California, in the early days, many words came into use and have since remained in general circulation, for example, Placer, Prospecting, Diggings, Pay Dirt, Gulch. Bonanza is of later introduction. Crevasse is a breach in the embankment of a river; the word is of French origin in the province of Louisiana and specially denotes the effect of a flood of the Mississippi River. Of like origin is the word used to designate the embankment of the Mississippi, Levee. The word is also used to designate a river front of towns situate on other rivers in the Mississippi valley which are naturally confined within their own banks. In English usage Levee is accented on the first syllable, but in the United States the accent falls usually on the last. Incidentally it may be remarked of another American usage of the word Levee to signify an evening reception of visitors by the President of the United States, "the President's Levee," that it is a rank solecism, and means in effect *a morning reception in the evening.* Freshet, in obsolete English usage, meant a stream of fresh water: in the sense of an inundation it is an Americanism. Blizzard, signifying a violent, blinding storm of wind, snow, and sleet, is a word of unascertained origin. Prairie is as distinctly American as Veldt is South African or as Tundra is Russian and Siberian.

In the vocabulary of politics, besides Logrolling, already mentioned, we have Gerrymander, to make an unfair distribution of electoral districts for party ends: this American political trick is called by the English political philosopher Jerrymandering; and one of the English dictionaries gives as an alternative spelling Jerrymander, while in Gerrymander it makes the g soft: thus pronounced, the word Gerrymander is a Briticism. What for the British is a political canvass is for us a Campaign, and a Campaign is conducted to a considerable extent in accordance with the tactics and strategy of real war. The successful party is the Victor, and to him, under the ancient laws of war, belongs the spoil. Speaking from the Stump, Taking the stump, were originally literal expressions of fact. Buncombe, or Bunkum, seems to be authentically derived from the name of a county of North Carolina, whose representative in Congress, when begged not to weary the House with his oratory, replied that though he was addressing the House he intended his speech for the good people of Buncombe. The derivation of the word Caucus from Calkers is plausible. In 1770 the calkers and ropemakers of Boston held frequent meetings to denounce the British government and its local agents, and those meetings were called by the Tories Calkers' meetings. The Caucus, a preliminary meeting held for the purpose of selecting a candidate for office, or, in case of a legislative body, to decide upon the policy to be supported by members of a party in the open sessions, is an American invention; of late it has been introduced in England. Spread-Eagle oratory has its name from the extravagant style of stump orators and Independence Day spouters when they glorify the Bird of Freedom. Highfalutin, a word that cannot be traced to its original source, denotes turgid, bombastic oratory. To Enthuse is unquestionably an Americanism, and it is base coin formed from the word enthusiasm, which, whether in Greek or English, has no corresponding active-transitive verb form. Of party names and nicknames may be mentioned Whig and Tory, of the pre-revolutionary era, Federal and Republican of the period after independence, then Whig again, and instead of Republican either Democratic Republican or simply Democrat, with the nickname (about 1835) Locofoco (given first to a body of radicals who, in Tammany Hall, New York, after a meeting was officially dissolved and the lights put out, produced locofoco matches, rekindled the lights and continued the meeting: the locofoco match, or locofoco cigar was introduced in 1834, the word meaning "substitute for fire"— *in loco foci.* It was a cigar with friction-match attached). Other party names and nicknames are Republican, Silver-grays, Copperhead, Carpet-baggers, Lily Whites. The man in any political organization who possesses or is believed to possess authority to dictate the party's policies is the Boss. The word is the Dutch *baas* and is the usual designation of an employer or overseer of workmen. A few years ago political terrorism in the South, designed to bar to negroes access to the polls, was known as Bulldozing, a word which cannot be traced to its origin with certainty, and which is no longer in use. Roorback is a false and injurious report set afloat in the crisis of a political campaign, usually a very short time before the canvass is closed, so that it may have damaging effect before contradiction or refutation can be made. The phrase "a good enough Morgan till after election" recalls an incident in the history of New York politics. William Morgan, author of a book purporting to reveal the secrets of Freemasonry, was kidnapped, and the anti-Masonry party charged the Freemasons with having murdered him. To counteract this charge, which was credited largely by public opinion, the Masonic society, or rather its friends in the Whig and Democratic parties, spread reports of the finding of the missing man; whether true or false, these reports furnished "a good enough Morgan till after election."

Right, as equivalent to very, is by some writers classed among Americanisms; but that is an error, though undoubtedly the word is more commonly used in that way here than among the English. In the style Right Reverend, Right Worshipful, etc., Right has the meaning of very: in Tyndale's Bible occur such phrases as Right sorry, Right humble, and in writers of the 14th century the same usage is to be seen. But Right here, Right now, Right away, Right off are Americanisms and are not found in the colloquial speech of Britain. In British English of these latter days Sickness is hardly used save in the sense of nausea; but the best British authors do not countenance that restriction of meaning. In the United States, outside the circles in which the time o' day is

given from London, the words Sick and Sickness have the same signification they have had in the general language at least from the 14th century, when mind-sick, mind-sickness, were current phrases; and in the King James version of the Bible sick and sickness have the same purport which they have in the American vernacular. Ugly, in the sense of cross-grained, ill-natured, is an Americanism, though English usage has the nearly parallel phrase, an ugly customer. An American can ride in a coach; but an Englishman, if he is to ride at all, must go on horseback or be borne on the back of some other animal. British restriction of the meaning of Ride is inconsistent with the usage of the translators of the Bible, who make Joseph, for example, and Jehonadab ride in chariots. The garment which Americans style Vest is better styled by the English Waistcoat. Peart, pronounced, and often written, Peert, meaning lively, brisk, sprightly, without any suggestion of sauciness or "freshness," is gone out of use, at least of literary use, in England: it is an Americanism, but its habitat, so to speak, is restricted. A special use of Peart is to signify the improved tone of one who is recovering from a sickness.

The place of business at retail which in England is a Shop is in the United States a Store. Of late a tendency has appeared toward adoption of the British usage of these terms. In regions unaffected by this tendency Shop is still what it was 50 years ago in this country, a work-place, and a Store is a place where goods are kept in store for sale. But even while Shop and Store retained their cis-atlantic meanings, there were numerous phrases current which are inconsistent with the American meanings of Store and Shop, for example, Shop-worn, Smelling of the shop, Shop-boy, Shopping, Shopkeeper, Shop-lifter, etc. The grocer's store or shop is here called a Grocery, not so in England: there Grocery signifies only the wares sold by a grocer. Unquestionably American is the use of the word Drummer in the sense of one who solicits or touts for custom. The phrase, He struck oil, will probably survive after all the oil wells have gone hopelessly dry.

What we call Baggage is by the British called luggage, though the reason of the difference can hardly be that we travel with less impedimenta than they. The development of our railway systems has brought many new words into the vernacular, but none more expressive than the verb Telescope.

The conversational speech of Americans at one time seemed to be seriously threatened with invasion by a host of spurious, illegitimate word-coinages, especially of verbs made out of nouns, as to Advantage, to Ambition, and of pompous verbs made out of nouns ending mostly in *-ation*, as Orate, Donate; but that danger was happily averted. The use of Transpire in the sense of happen, occur, is of American origin, but the use quickly spread to England: the solecism was promptly branded by scholars, but it still lives and flourishes. Balance, in the sense of remainder, is another Americanism which has attained a currency which it does not deserve. Mad, in the sense of angry, is an Americanism of the baser sort. To Wilt, on the other hand, a "provincialism" in England, but in America a word in universal use, is one of the valuable contributions of the American province of the English language to the mother tongue's general store. The proverbial Whittling of the Yankee keeps alive an ancient native English word for knife.

Among notable or curious phrases current in the United States may be mentioned Flying off the handle,— losing self-control through passion: one is then like the axe-head which has quit the haft. To Get religion, or even to Take religion, is a phrase constructed on the pattern of "to take a cold" or "to take the measles." To be Posted plainly had its origin in the counting-room.

JOSEPH FITZGERALD,
Author of 'Word and Phrase.'

Americanists (from *Americanistes*), all those who devote themselves to the study of (1) the native races of America — their origin, distribution, history, physical characteristics, languages, inventions, customs, and religions; (2) the history of the early contact between America and the Old World. The name was probably first given to the members of the French Société Americaine de France, and later to students of any nationality who are interested in the archæology, ethnology, and early history of the two Americas. Since 1875 such students have met at irregular intervals in an association known as the Congrès International des Americanistes. This congress grew out of the Société Americaine de France, which was formed in 1857 by several French students who had become interested in the pre-Columbian civilizations of South America and Mexico; after this society had flourished for 18 years its members decided to invite Americanists of foreign countries to a congress. The first international meeting was held in 1875 at Nancy, France, where statutes were adopted and plans laid for the continuance of the organization. Since then ten other meetings have been held in various European cities, and two in America (City of Mexico, 1895, and New York city, 1902). At first the intention was to hold biennial sessions, but after a few years it was decided to meet at irregular intervals, the council of each congress determining the time and place of the next session. The meetings have a polyglot character, as speakers may use either French, German, Italian, Spanish, or English. The addresses may be either written or oral, and are limited to 20 minutes in length. All papers presented may, with the approval of the committee, be issued in the printed 'Proceedings' which are usually in French ('Congrès International des Americanistes, Comte-Rendu'), and published in two volumes for each meeting. In addition to the papers the reports contain

lists of the members enrolled and minutes of the business transacted at each session. Any one interested in the subjects discussed may become a member of any congress by a subscription (three dollars, American money, or an equivalent in the currency of the country where the congress meets), which entitles him not only to take part in the sessions but to receive the reports of the congress and all other publications issued by it. The subjects considered at each meeting range through meteorology, geology, archæology, and ethnology to comparative philology, the history of the pre-Columbian arts and religions, the early discoverers of America and its early relations to European nations. Representatives from almost every nation, even from China and Japan, are found on the lists, which have included as members (not necessarily as attendants) many of the most eminent archæologists, ethnologists, and anthropologists in Europe, England, and America. For a full account of the 13th congress, held at the American Museum of Natural History in New York city 20–25 Oct. 1902, see 'Science,' New Series, Vol. XVI. p. 884. Previous meetings are reported in 'Nature,' Vol. XIV. p. 355; 'Popular Science Monthly,' Vol. XXXIV. p. 686; and Vol. XXXVIII. p. 685.

American Jewish Historical Society, an association organized in 1892 for the purpose of collecting and publishing material bearing on the history of America. It is a national organization with a membership of 243. President, Dr. Cyrus Adler; secretary, Max J. Kohler.

American Labor. According to the census of 1900, the total number of people in the United States engaged in gainful occupations of all kinds was 29,074,117, of which number 23,754,205 were males and 5,319,912 females. These figures include wage-earners and wage-payers, employers and employees, engaged in manual and professional service. Of this number between 18,500,000 and 20,000,000 may be reckoned wage-earners. And although statistics are lacking, we will not be far astray if we estimate that the corresponding classes at the beginning of the national existence numbered about 500,000.

As to the racial composition of this class, four fifths of the population of the United States at the close of the Revolutionary War was of English descent, but at the present time careful consideration would indicate that only about one half of our population can claim the English as their mother tongue; and yet, during the first quarter of the 19th century, immigration could not have affected the nationality of our working people to any great extent, nor until 1840. In 1833 the largest number in the first third of the present century arrived, being 58,640 immigrants. Great impetus was given in the forties by the famine in Ireland in 1846–7, and by political causes in Germany. The total immigration since the Revolutionary War and up to July 1901, was 20,253,073, while the foreign-born residing in this country at the census of 1900 was 10,460,085, being 13.6 per cent of the whole population. These large additions to our population had a marked influence upon our industrial conditions, because in the very nature of the case their numbers, almost *en masse*, went to swelling the ranks of labor. The manufacturing and mechanical industries absorbed a much larger proportion of the new element than agriculture, and the tendency of our immigrants to assimilate with our mechanical industries increases the supply of labor in comparison to the demand, and at times may have lowered wages and crippled the consuming power of the whole body of the population. But this was not serious, and it may have been imperceptible, for at the time of the accelerated movement of immigration there was a vast development of the railroad interests of the country, which could not have been carried on so extensively and completely without a large body of common laborers. Immigration supplied this labor, but it soon began to find its way into organized industry. As the tendency of wages has been constantly upward since the close of the 18th century, it cannot be argued that the assimilation of immigrants with our own native labor has reduced wages, but it can be assumed that such assimilation may have retarded their increase beyond what was experienced. During the years of depression after 1893 immigration was checked, but with the renewal of prosperity during the past few years the movement has practically assumed its old proportions of nearly half a million a year. The character of immigration has changed, and this change has not been for the better. If immigration could be left entirely to natural motives it is quite evident that the movement would be retarded gradually, but it is stimulated by transportation companies, in their desire to secure business, to such an extent that a large body of objectionable immigrants are brought here. When it is known that an immigrant can be transported from Italy to Chicago for less money than a first-class passenger can travel from New York to Chicago, it is not strange that people flock to the United States; and during this past decade it is quite certain that labor in America has suffered through this class of immigration, especially in mining districts, where wages have been kept down and much distress has prevailed through the influx of cheap foreign labor.

At the nation's beginning its labor was domestic, and working people were engaged in agricultural pursuits, the fisheries, and in the clearing of forests, while a small percentage were engaged in what is known as domestic manufacture and in commerce. The factory system, dating from 1790 as the year of its birth, did not become influential until after 1820. With the complete establishment of textile factories, in 1813, at Waltham, Mass., where the first complete factory in the world for the manufacture of finished cloth was built, labor began to find a new avenue of employment, and the young women of the rural districts were induced to enter factories as spinners and weavers. Thereafter growth of the textile factory was rapid, both in New England and the Middle States. Fair wages and easy work attracted the women of our own country, and English girls, until Irish immigration commenced, and during the last 25 years or more the Irish operative has been giving way gradually to the French-Canadian and representatives of other nationalities.

Of course, all manufacturing received a great impetus during the Revolutionary War, when our people were obliged to furnish their own supplies. At the close of the war these efforts ceased or production was greatly reduced, and

America was still a subject of Great Britain in respect to its manufacturing interests, until the complete establishment of the factory system. The old domestic or hand system was not long in passing, and the régime of invention and machinery holds full sway. Along with this change in the method of production, mining has been developed to an enormous degree, until now the United States produces more iron than Great Britain. This industry has brought into employment a vast body of skilled workmen, and the ramifications of the industry still greater forces. Our large towns and cities are, as a rule, thoroughly equipped with sewers, and the manufacture of pipes and mains for this purpose, as well as the manufacture of gas-pipes and mains and plumbing work generally, has been the result. These latter changes have occurred within the last 60 years.

be seen from the accompanying table. This change was largely brought about by the factory system, under which women could attend light-running machines with skill and with fair remuneration. They constitute a new economic factor in industry, and being a new economic factor, they cannot as yet hope to receive liberal wages. It can hardly be said that they have displaced men, but they have displaced boys and girls to a considerable extent. The first tendency under the factory system was to employ children, and the number constantly employed increased from year to year until the last 25 years, when the number has been rapidly on the decline. Public sentiment voiced by legislation, as well as the economies of production, is driving the children out of our factories; women are taking their places. In some industries men have taken the places of women, the change of the form of work result-

NUMBER OF MALE AND FEMALE WAGE-EARNERS REPORTED FOR PRINCIPAL OCCUPATIONS IN 1900.

Occupations	Males	Females	Total
Agriculture, Fisheries, and Mining:			
Agricultural laborers....	3,747,668	663,209	4,410,877
Fishermen and oystermen	67,715	462	68,177
Lumbermen and raftsmen	71,920	100	72,120
Miners and quarrymen..	562,501	1,365	563,866
Stock-raisers, herders and drovers	83,056	1,932	84,988
Domestic and Personal Service:			
Barbers and hair-dressers	125,542	5,574	131,116
Bartenders	83,377	440	88,817
Engineers and firemen (not locomotive).....	223,318	177	223,495
Housekeepers and stewards	8,224	146,929	155,153
Laborers (not specified)	2,505,287	123,975	2,629,262
Launderers and laundresses	335,282	50,683	385,965
Nurses and midwives...	12,265	108,691	120,956
Servants and waiters...	276,958	1,283,763	1,454,791
Watchmen, policemen, and detectives........	129,711	879	130,590
Trade and Transportation:			
Agents (claim, commission, real estate, insurance, etc.) and collectors	230,606	10,556	241,162
Bookkeepers and accountants	180,727	74,153	254,880
Clerks and copyists....	544,881	85,246	630,127
Draymen, hackmen, teamsters, etc........	538,029	904	538,933
Hostlers	64,850	79	64,929
Messengers and errand and office boys.......	64,959	6,663	71,662
Sailors and boatmen....	78,253	153	78,406
Salesmen and saleswomen	461,909	149,230	611,139
Steam-railroad employees	580,462	1,688	582,150
Street railway employees	68,873	46	68,919
Stenographers and typewriters	26,246	86,118	112,364
Telegraph and telephone operators	52,459	22,556	75,015
Manufacturing and Mechanical Industries:			
Bakers	74,860	4,328	79,188
Blacksmiths	226,284	193	226,477
Boot and shoe makers and repairers	169,393	39,519	208,912
Butchers	113,578	378	113,956
Carpenters and joiners..	599,707	545	600,252
Cotton-mill operatives...	125,788	120,216	246,004
Dressmakers	2,090	344,794	346,884
Iron and steel workers..	287,241	3,370	290,611
Machinists	282,574	571	283,145
Marble and stone cutters	54,317	143	54,460
Masons (brick and stone)	160,638	167	160,805
Milliners	1,739	86,120	87,859
Painters, glaziers, and varnishers	275,782	1,759	277,541
Plumbers and gas and steam fitters..........	97,659	126	97,785
Printers, lithographers, and pressmen.........	139,166	15,981	155,147
Saw and planing mill employees	161,251	373	161,623
Seamstresses	4,837	146,105	150,942
Silk-mill operatives.....	22,023	32,437	54,460
Tailors and tailoresses..	160,714	68,935	229,649
Textile mill operatives (not otherwise specified)	53,437	51,182	104,619
Tin-plate and tinware-makers	68,730	1,775	70,505
Tobacco and cigar factory operatives	87,955	43,497	131,452
Wood-workers (not otherwise specified)......	104,468	6,805	111,273
Woolen-mill operatives..	42,566	30,630	73,196

The change in the system of work has practically done away with apprenticeships, their place being more than filled by manual training and the work of the trade schools. With the establishment of the factory system apprenticeships were less obligatory. By 1850 the resort to them was waning, while since the vast development of the factory system, especially subsequent to the Civil War, they have been still less prevalent. Another great change which has come in the way of industry is the employment of women, who were engaged only in domestic labor, except in rare instances, in 1789, but are now represented in almost all industries, as may ing in such displacement. Laundry work is practically factory work now; and the old domestic hand weavers, who were to a large extent women, have seen their work transferred to the factory. These industrial revolutions have carried with them other changes, which perhaps are more ethical than economical in their relations. For instance, under the old system of labor, employers had a paternal relation to their employees, and even in the early cotton-mills in New England the paternal system of caring for employees was adopted, notably at Lowell, and later on also in Manchester, Conn., under the Cheneys' administration of the silk works; but

as the factory system has spread, this paternal care has been lessened, although during the last few years there has been a great revival in the discussion of the usefulness of such paternal oversight. The public is considering this question, and great employers here and there are trying the experiment of taking an interest in the home welfare of their employees as well as in their efficiency.

The changes in the industrial system have had many ramifications. The labor movement in this country began with the 19th century. Prior to the establishment of the factory system there was little organization. Here and there a club of skilled workingmen existed, notably in the Eastern and Middle States. Since 1825, however, the movement has been rapid, and its results, while not always satisfactory, are indicative of real progress. In the early years of the labor movement many arguments were advanced against it, and the attempt made to prevent workingmen from joining in organization. The merchants and ship owners of Boston, at a meeting held in the Exchange Coffee Rooms on 15 May 1832, voted to discountenance and check what was called the unlawful combination formed to control the freedom of individuals as to the hours of labor, and to thwart and embarrass those by whom they were employed and liberally paid. It was held everywhere that labor ought to be left free to regulate itself, and that neither the employee nor the employer should have the power to control the other; and the stock argument that organization would drive trade from the country was resorted to. But the condition of labor as it now exists is a vast improvement upon its condition at any other period. It may, perhaps, be well simply to say that wages, even during the past half-century, have increased, on the whole, something over 60 per cent, while the general course of prices has been downward, and to such an extent that the relative real wages — that is, wages measured by wholesale prices, and showing, on this basis, the purchasing power of money — have increased over 90 per cent since 1860. To-day organized labor has many defenders. It is looked upon with disfavor in some quarters, but as a rule, employers are quite willing that their employees should organize, for they have their own organizations and do not feel like denying the right to others. Of course, a very large proportion of the working people of this country is unorganized, and I presume this is true of manufacturers and employers on their side; but as the methods of production are brought to a larger and grander scale, organization in every direction will more and more prevail. At present organized labor is estimated at 2,000,000. This is the result of an estimate based on the claims of different organizations. I am inclined to think it is too liberal an estimate, and yet, placed in comparison with 18,500,000 wage-earners, it does not seem large; but, as a rule, organized labor is employed in the manufacturing and mechanical industries, and in this sense the percentage is high. The proportion of organized manufacturers to the whole body is probably much larger. As the labor movement has grown, strikes have become more frequent, and while undoubtedly the era of strikes is passing away, yet it will be some time before the downward scale is reached as to numbers and importance. The great strikes in the country have had a marked influence in many directions. They have excited working people to undertake other strikes; they have brought bitterness between employer and employee, and yet on the whole they are bringing a new line of thought to the public mind, and their study will result in good to all classes. Strikes are teaching the public its interests in industry as over against the personal and selfish interests of the two parties immediately involved.

The labor question has met with a great change as a result of the Civil War. Our negro population has lost some of the old occupations in which it was engaged in the North half a century ago, but it is gaining others. In the South the employment of the negro is becoming more varied and his condition more hopeful as one of pecuniary prosperity. Negro labor is abundant, good, and steady in certain lines. The question is often asked, whether the division of employment lessens the quality of work. Probably not, for the great principles of modern industry are association, concentration, and specialization. With the first the second is absolutely essential, and the third is the result of concentration. If these things lessen the quality of the work, then the opposite must be true — that without them quality is improved. This carries the argument too far. If there is much truth in it, then the simplest, humblest kind of work is best for the worker, and sawing wood and paving streets, the most ordinary manual toil, would be better for the worker than the employment of his intellect in tending a machine.

Working people have experimented with co-operation, profit-sharing schemes, and other methods of increasing wages. These experiments have met with varying success. They are likely to do some good, but it will be a long time before the moral character of the men involved will permit successful management of co-operative schemes. The co-operative principle is that of our modern system of industry. Pure co-operation, probably, cannot succeed, from an economic point of view, but the co-operative spirit can prevail to a higher degree than it now does; and these things have reduced the hours of labor from 11, 12, and 13 per day to 8, 9, and 10 per day. These changes, however, came gradually, and as the result of improved methods of production. Then law stepped in and made the custom the public voice. The first ten-hour law in this country, however, was not passed until 1874, when the State of Massachusetts provided that women and children should not be employed over ten hours a day in the textile factories of the State. Another specific change which has come is the frequent payment of employees for their services. The method in former times was to pay the working people part in cash and part in goods, and settlements were made at long intervals. Now everywhere, with a few exceptions in the West, where to some extent the truck system still prevails, cash payments at short intervals are the rule. This change has been brought about both by public sentiment and by statutory enactments.

One of the greatest changes which has been wrought by the new system has come through corporations. When the century began, the workingman and his employer were practically associated. With the establishment of the fac-

tory system there came the necessity of using large capital, more than one man or a firm of men contributing; so the corporation became a necessary factor in the development of industry. The ethical relations between employer and employee were changed at once. In this way the organization of labor has grown on the ground that one organization should deal with another; that if the stockholders lose their personality and are represented by a manager, the large body of working people lose their personality, and their interests should be represented by a manager or a committee. One of the vital changes resulting from this growth of corporations is the liability of the employer to the employee for damages received while in the employment of the corporation. The old common-law rule relating to the liability of employers for accidents occurring to their employees is that a workman cannot recover damages for injuries received through the carelessness or negligence of a co-employee, although a stranger may recover for an injury following the same carelessness or negligence. This rule grew up under the domestic system, when employer and employee worked side by side. But when expanded methods are introduced this old rule becomes somewhat ridiculous. Yet, as the common-law rule grew up before great industrial enterprises were established, courts have been governed by it; but now it is being broken down by statutory restrictions in different parts of the world, although it still holds good in many States. There are very many other points where changes in relationship have been made by the change in system. Looking the field over broadly, the conclusion must be reached that on the whole the working people have been gainers during the progress of the past century — gainers not only in wages, both real and nominal, but in their relations to society.

To a very marked degree, as was long ago pointed out by De Tocqueville, the American nation consists of workers. Such wealth-aristocracy as there is in the country is almost always traceable back by the remove of a generation or so to a hard-working ancestor, of "the laboring class." At the present time the younger members of very wealthy families are devoting their time and service to labor as assiduously as if their subsistence depended upon their earnings. In America, therefore, labor holds a more honorable place in the minds of all the people than it does in any other land, and individuals can look forward to the highest class of associations, both social and intellectual, as a result of their application of skill, provided always they are ruled by integrity, and shall build up a character which will sustain itself under all conditions. A study of conditions, however, proves that the base of the social structure is growing narrower as time, as education, as a wise altruism lead men out of their lowly conditions to a better plane; and the American laborer everywhere is an active, earnest, and, I believe, an honest factor in keeping up the struggle to secure a higher standard of living.

Our 18,500,000, and over, of wage-earners constitute a vast body on whose prosperity, intelligence, and moral worth is based the welfare of the Republic. With their happiness goes the happiness of the whole people. But they demand something more than is indicated by contentment, for their experience with American inventions and educational systems teaches them that from rude instruments of toil they have become intelligent factors, in both a social and a political sense. So it is they join in the great struggle to lift themselves to a higher plane of living. All the disturbances which we have seen during the past score of years, and which seem, superficially considered, to indicate that we are approaching an industrial war, are but protests against fixed conditions. These disturbances often arise from unwise considerations and from ignorance of the conditions of production, but they all indicate one grand trend, and must be considered as a part of the progressive movements of our age. These views constitute the chief elements of what is known as the labor movement, in which American labor has actively participated for a great many years — first, seeking organization; second, by organization, making its protests and issuing its demands. Philosophically, these protests and demands must be viewed as educational factors and not as war factors.

"Labor," Ruskin says, "is the contest of the life of man with an opposite; the term 'life' including his intellect, soul and physical power, contending with question, difficulty, trial or material force. Labor is of a higher or lower order as it includes more or fewer of the elements of life; and labor of good quality, in any kind, includes always as much intellect and feeling as will fully and harmoniously regulate the physical force." So the struggle of the wage-earner becomes of that high order which insists upon recognition as a factor in securing to all people something beyond the mere wants of existence. A man who is working simply to secure food, shelter, and raiment, that is, the conditions absolutely essential to keep him an efficient working machine, is not the best product of civilization; but the man who is willing to work industriously to secure these absolute necessaries to make his services efficient, and then, over and beyond them, something of the spiritualizing necessaries of life, is a credit to our civilization; and these spiritualizing influences can be secured only when, after paying for the necessary lubrication of his working muscles, he is able to furnish himself and his loved ones with elements of life which have heretofore been considered luxuries. He must be able to secure something of these higher elements, or he loses, and retrogression is the result. He must be able to educate his family, and to give them of the best things of life to such an extent that they become active participants in the results of invention, which throw around life everywhere more than could be secured under old conditions.

From what has been said it will be clearly understood that conditions are not always favorable; that there are fluctuations, business depressions, having their discouraging influence, and strikes, unsettling the public mind. The clash between ethical and economical conditions leads to disruptions sometimes in business associations, and arrays, to all appearances, capital on the one side and labor on the other, and gives color to the occasional prophecy that this clash will lead to bloody strife. The causes for this clash are mostly ethical, growing out of the relations of men and the lack of appreciation of the duty which is owed to the public. Macaulay said that the evils arising from liberty were only to be cured with more liberty. So the evils

which apparently surround us at the present time, and which apparently grow out of the industrial world, are the results of an intelligence which did not exist in the past, and the cure for them is more intelligence. Capital and labor are intelligent enough to get into difficulty; they are not always intelligent enough yet to keep out of difficulty. It requires a very high moral character on the part of both employer and employee for each to recognize the rights and the privileges of the other; but with this recognition, quarrels, as such, will largely cease, and contests of mind will take the place of those unhappy contests which are now so frequent. When the employee recognizes that his highest social duty is to render the very best service of which he is capable, and the employer recognizes that his highest social duty is to compensate the best service with the best wage, a vast deal of friction will be avoided. Integrity of business involves both the employing and the employed elements of society. Confidence in each other is the surest cure for many of the difficulties, and while the world is growing altruistic, it will not grow altruistic at the expense of individual development; but after the rendering of the best social service there will come a co-ordinated force involving both altruism and individualism. Either means destruction in a degree. Co-ordination means success and reasonable happiness. The ethical force cannot rule at the expense of the economical, nor can the economical force rule at the expense of the ethical. Their co-ordination is the true line of progress. As American labor comprehends this more and more clearly, and I believe it is comprehending these principles, and as the employer comprehends them more and more clearly, we may hope for the adjustment of difficulties on a plane of moral responsibility not yet reached, except incidentally. The settlement of labor controversies is one thing, their prevention another. If the intelligence of different elements has not reached that degree whereby they can be prevented, then there should be some recognition of that settlement and adjustment which recognize the importance of each side in the success of industrial enterprises.

Carroll D. Wright,
U. S. Commissioner of Labor.

American Legion of Honor, a beneficial fraternal organization founded in 1878; reported for 1902: total membership, 6,386; grand councils, 8; sub-councils, 260; benefits disbursed in its last fiscal year, $628,156.

American Literature. A hundred years ago and for half a century afterward, every assembly of students in this country was entertained by discussions on a "Possible Literature" of America,— how soon there would be an American literature was a favorite question, grief or complaint that there was not an American literature came in if the speaker or writer were of cynical vein. The introspection which was thus developed among people who were born for something better than introspection had its good results. Every printed word, one may say, was collected, which showed that between 1602 and the 19th century, any man or woman had written anything in America. Such a collection as Samuel Kettell's 'Specimens of American Poetry' shows the eagerness with which critics who were forecasting a glorious future for our literature were willing to preserve all the crystals from the past and eager to persuade us that they were jewels. The truth seems to be that for the 17th and 18th centuries there was no class of men or women who would now be called "literary people." At the same time, the new settlers and the men and women of half a dozen generations which followed, said what they had to say, and generally said it well. For they did not think much about the way of saying it, they did not talk much about it, they had no professional critics. There were among them those who "harked back" to English models. After the establishment of newspapers (see Newspapers), which runs back to the year 1704, the sad necessity of journalism (q.v.) compelled the press to create every week a given number of square inches of what is called "matter." Thus, there appeared in the three cities a few of those writers who have to write as much when they have nothing to say as when they eagerly proclaim something not known to the world before.

It was not until 1555 that in the printed books of England the first fruits of the discovery of America appear. Richard Eden then published his translation of Peter Martyr's 'Decades,' and he adds to them some new narratives of voyages not described in the original. An English translation of Ribaut's 'Florida' was printed in 1563. In 1576 the first edition of Sir Humphrey Gilbert's plea for a northwest passage appeared, and an account of Frobisher's voyages was published in 1578. In 1582 we touch solid ground as we come upon the name of Hakluyt. The Island of Roanoke has the honor of furnishing the first original American work to English literature. The four letters of Ralph Lane, who was the first commander of Raleigh's first colony, are the oldest American writings now extant of any Englishman and were perhaps the first ever written. They were written 12 Aug. 1585 from what he calls Porte Ferdynando. One of them was to the famous Sir Philip Sidney. They were printed in 1860 for the first time in the Transactions of the American Antiquarian Society. The English archives have now been thoroughly searched and have probably yielded up all that can be found in them of intercourse with America in this mythical century. There are two or three narratives of the adventures of sailors who straggled from Mexico, where the Spaniards had made them prisoners, to the fisheries of the northeast, where they were relieved by the fishermen. The earliest of these is dated in the year 1582. In the collections of Hakluyt and Purchas will be found other narratives of a similar character which struggled into print in one way or another. Professor Tyler in his admirable survey of the subject, places the year of the birth of American literature in the ode of Michael Drayton, published in 1607, the year always assigned as the birthday of the nation, the year of the birth of Virginia, the year of John Smith and Powhatan and Pocahontas.

The history and criticism which belong to this subject have been admirably handled by the Messrs. Duyckinck, by Professor Tyler's 'History of American Literature from Colonial Times,' by Mr. Kettell, who has been named, and by Professor Charles F. Richardson's 'American Literature' (1607–1885). It must

be enough here to say that Captain John Smith in his various accounts of Virginia and of his voyages on the coast, created a real interest in that "brave new world which hath such people in it." Dr. Tyler refers also to George Percy, William Strachey, Alexander Whitaker, John Pory, and George Sandys. The original editions of the publications of these men are now among the most interesting nuggets of the book collectors. The Hakluyt Society has republished many of them and has proved its value to the students of our early history. There is one interesting tract of Strachey's which would answer one pathetic question. He says, "Before I have done I will tell you the story of the lost colony." But in nothing that has been found of Strachey's is that history told.

That school of historians whose habit is to draw a blue pencil, as the trade says, across everything entertaining in history is fond of stamping John Smith as a liar wherever he goes outside Sandy Hook or Lincolnshire or the Strand. It is the fashion of to-day to throw the story of Pocahontas overboard and even Dr. Tyler, who is sympathetic, calls it the "fable of Pocahontas." But this is to be said, when 100 men trained like cockneys, embarked on an unknown sea, explored an unknown bay, tried the adventure of an unknown river, talked in an unknown language with a savage chief who has never heard of such people before, the incidents of such acts when written by them will not be exactly like those of a London counting room or of a college lecture room. The Hungarian gentlemen, I believe, find Smith's account of Hungary and its Turkish wars intelligible and reliable. Smith's surveys of Massachusetts Bay are entirely intelligible and show an accurate acquaintance with the region which he describes. Now, it is hardly fair when you can verify an old author's personal narrative in nine cases out of ten, to say in the tenth case that he is a liar, simply because you have no material for verification, on the one hand, or contradiction. on the other. Close after the little series of Virginian writers came the series of the Massachusetts historians. They also have been most carefully edited; and it is now only by a fortunate accident that a student of to-day is able to add any anecdote new to other students regarding the first generation of New England. The journal of William Bradford, one of the first governors of the Plymouth Colony, has a story which is dramatic. With a fortunate prescience of the value of every word which related to the Plymouth emigration, William Bradford wrote the 'History of Plymouth Plantation.' His sons and indeed all the people of the old colony knew of the exceeding worth of this volume. It was used by Morton, Prince, and Hutchinson and the others of our earlier historians. A great part of it was copied and from the copy thus made it was consulted by our historians till the year 1855. In that year a quotation from it, which was not in our copies, appeared in Bishop Wilberforce's history of the English Church. On inquiry it proved that this gentleman had consulted the original which was in the Library of the Bishop of London in Fulham Palace. He immediately gave permission that the whole should be copied on the request of Mr. Charles Deane. Subsequently, as a result of the efforts of Senator Hoar, the various authorities in England gave back the precious manuscript to the State of Massachusetts, and it is now one of the treasures most sacredly preserved in the State House in Boston. As Dr. Tyler calls Drayton's ode the beginning of American literature, the Massachusetts people may well call William Bradford's chronicle the beginning of the literature of New England. It should not be forgotten, however, that the letters containing the accounts of Gosnold's unsuccessful colony in 1602 were written before the time when Bradford began to write his history.

When the larger colony of Massachusetts Bay was formed the general court of that colony, according to a very early record, directs that paper books shall be furnished for preserving all journals by the first settlers. Fortunately for their successors, Governor John Winthrop in the midst of all his other cares used his manuscript books, and his notes made almost daily are now cited as Winthrop's 'History of New England.' They cover the period from 29 March 1630, when he sailed from England, to 11 Nov. 1648. It is a convenient aid to memory that Winthrop's death followed close on the execution of Charles the First. Sadly enough all the other blank books thus furnished seem to have served other purposes from that for which they were intended. They were perhaps, used for sermons now forgotten, or possibly for cartridges so soon as cartridges were invented. Such materials for the early history as have been preserved have generally been printed by the care of historical societies or similar agencies. There is a charm about them such as belongs to all fresh narrative where the writers are thinking of the thing done and not of the methods of expressing it. This charm which hangs around Columbus' 'Letters'; Sir Thomas More's 'Utopia'; Defoe's 'Robinson Crusoe'; Swift's 'Gulliver's Travels,' is the same charm which is to be found in Purchas and Hakluyt and the early narratives of those who wrote by the light of a pine knot with pens made from a bird's wing. In such simple utterances we are to look for the first handiwork of American literature.

The first graduates of Harvard College made a class of nine young men, six of whom sought their fortunes in Europe. The year of their Commencement was 1642, and the theses are preserved in which according to the custom of their time, they offered to defend 54 propositions against all comers. It has been observed by modern critics that all these propositions are now known to be false. This is a somewhat cynical statement with regard to them. But when one learns that these young gentlemen were prepared to prove that Hebrew is the mother of languages, one looks with caution upon their courageous statements on other points with regard to the heavens or the earth, the sea or the skies. Four of the number became clergymen. The name most distinguished in history is that of Sir George Downing, who did not distinguish himself for the courage of his convictions.

As early as 1639, the government of the colony had cared for its future education by the establishment at Cambridge of a printing plant. This was done almost simultaneously with the establishment of Harvard College by the same authority. And it was a good omen that the first publication ac-

credited to the new printing house was the 'Freeman's Oath,' as ordered by the general court, to be taken by those who were chosen into the company. Universal suffrage was not yet dreamed of even by Sir Thomas More. The first book which can be called a book which appeared from the press, was the 'Bay Psalm Book,' the work of Thomas Welde, John Eliot, and Richard Mather.

John Eliot already looking forward to his work among the Indians was making his first studies of the language of the people for whom he cared. The modern students speak of this language as the Natick dialect of the Algonquin tongue. Eliot's work was of the first importance and before he died the publications in that language alone of books printed either in our Cambridge or in London makes a department in literature of more than 30 volumes. These books were printed to be used in wigwams and log cabins. The copies which strayed into libraries were but few and those Indian books of that century which remain are among the rarest treasures of the collectors. Of Eliot's 'New Testament' in the first edition there are but 14 copies. Of the second revised edition, published more elegantly, there are 39 copies. The work that Eliot gave in translating the Bible into the Algonquin tongue has been spoken of more than once as work thrown away. But to say this is absurd. Eliot proved himself to be one of the first philologists of any period of literature. His analysis of the Indian language is to this moment a guide to those who choose to study it. With the progress of discovery it has proved that the Algonquin language, of which the Massachusetts language was a dialect, was the language of more than half the Indians of our part of the Continent. To this hour it is spoken by the Catawbas who are living in North Carolina, the Pamunkeys who are living in Virginia, by the Delawares who have been carried from Delaware Bay to Kansas, by the Micmacs, Penobscots and other Indians of Maine and of the northeast, and even by the Arapahoes in the west. Northward and westward it is spoken as far as the tribes of the great Ojibwa family, far beyond Lake Superior, and often near to the Arctic Ocean. Of 300,000 Indians, more or less, now in the territory of the United States, more than half would have been understood in conversation by Massasoit and Philip. An admirable bibliography of Algonquin literature has been prepared by James Constantine Pilling. It is published by the United States Bureau of Ethnology. The work of devoted Moravian ministers in Pennsylvania in the same lines belongs rather to the next century.

Among the early settlers of Massachusetts was Anne Bradstreet, a girl of 18. She was the daughter of Thomas Dudley, who became the second governor of Massachusetts. She was the person called the «Tenth Muse» by Cotton Mather. Her poems, many of which were written before she came to America, are an interesting and curious memorial of the better educated colonists. She lived for most of her life at Andover in Middlesex County in Massachusetts Bay. The most diligent search in her poems shows hardly any reference to the outward aspect of the country in which she lived. Her flowers and her birds belong to the flora and fauna of England and not of Middlesex County. Between 1642 and 1700 Increase Mather and Cotton Mather, are the names most often referred to as we look back on our literary history. Of Increase Mather we have in print 85 publications, mostly separate sermons. Of Cotton Mather the collection is much larger, the number of titles being 382. The modern fashion is to speak of the Mathers with a sneer as bigots and to dismiss them from the lofty consideration of our time. But whoever remembers the duties to which they had to put their hands is disposed to regard them more favorably. There was but little subdivision of work for the men who had been educated to be the leaders of their country. And certainly some allowance is to be made for ignorance of the laws of electricity when the teacher whom you are judging has to study his electricity as Cotton Mather did while he encourages soldiers for warfare, while he checks the smallpox by inoculation, while he is writing the history of the past and is caring for the poverty of to-day. Franklin says in a letter of his to Cotton Mather's son, that if he himself had been of any value to the world, he owed it to Cotton Mather's 'Essays to Do Good.' It is rather hard to throw Cotton Mather overboard either as a quack or a fanatic when such a man as Franklin was willing to write for him such an epitaph. It is fortunate for this generation that at a comparatively early period of his life Mather brought together in his Magnalia historical papers which he had already written, some of which had been printed. The date of the first edition of the Magnalia is 1702, but the work belongs almost entirely to the 17th century. Cotton Mather was himself born in the year 1663, so that a good deal of his record of the history of the first settlement is put on paper at second hand. Occasionally an unfortunate error here has puzzled his readers. For instance, before the discovery of the original Bradford manuscript, we owed to Mather the statement that the Pilgrim Fathers came from Ansterfield in the county of Yorkshire. This proved to be the misprint of the London printer for Austerfield. It was only on the discovery of this error by the late William Hunter that the American pilgrimages to Scrooby and Austerfield begun. A good deal of injustice has been done Mather from what is in itself a comparative trifle, that his great book has not yet been edited by any competent editor. Even the detail that there is no decent index to it has greatly diminished its usefulness to historians in this generation. They ought to remember that he was but 39 years old when it was printed, and the corrections to his work which a man makes between 39 years of age and 60 nowhere appear in it. The reader is referred to the articles MATHER, INCREASE; MATHER, COTTON, and MATHER, SAMUEL, which in their place state what these men did for the growing colony during the period when it ceased to be a trading company and became really an independent State.

Thomas Hutchinson, a governor of Massachusetts, was a man of letters. And if he had not been the unfortunate governor whose disloyalty to the State gained for him the hatred of those around him, he would have been remembered with gratitude as such. He was an enthusiast about the history of the Pilgrims and of the fathers of Massachusetts. The first

volume of his ‘History of Massachusetts’ was published in Boston in 1764, and the second volume in 1767. Alas, he was not equal to the duties of a great crisis, he deserted his countrymen, and by his country was branded as a traitor. But for this he would be named to-day as the first in the series of distinguished American historians.

The assiduous and successful attention which has been paid to the century of colonization has very naturally given to New England readers a better history of what passed in the 17th century than we have of the first half of the 18th century. During that time the people of the United States were involved in war with France. This meant for them a frontier war in which every savage was commissioned by French or Jesuit authorities to descend upon the borders of the English settlers. Excepting the stories of frontier warfare, there was not much to write history about. There are a few exceptions but in general the crown governors sent over by William and Mary, Queen Anne, or by the first Georges were but a poor set. They initiated nothing and were well pleased if they could avoid a quarrel with the colonial assemblies. The one distinguished royal governor is William Shirley, who filled so well the duties almost unexpected, of a commander in chief of North America. So it happens that in reviewing the literature of the country we have no longer such unaffected and simple narrative. But we find ourselves more in the walks of religious speculation and of theology. In the front of the writers on such subjects is Jonathan Edwards, who challenged the attention of the learned in the English-speaking world by studies and results which have become famous. In the penury of frontier villages, and living day by day in what seems very petty surroundings, this distinguished man elaborated his studies on the divine counsels and placed his poor limits on the infinite in methods and language which will survive all other American literature of the first half of the century. It is inevitable perhaps that in the midst of such discussions of the Idea, there shall appear on the other side of the horizon discussions of the fact, or of those realities which men can see with the eyes and hear with their ears. And in our case, Benjamin Franklin was born into the world in the year 1706. Before he was a man he was well advanced in those studies of the English language which gave him afterward his power to express himself to men. Long before he was a statesman and diplomatist, he was conducting his experiments on electricity and when he drew the lightning from the skies, he attracted the attention of all the learned world of his time. When we speak of the American authors of those 50 years the fame of Edwards and Franklin overshadows all the rest. With the discussions attendant on the American Revolution, a new school of authorship began. It now seems clear enough that the more thoughtful leaders of English opinion were from the very beginning amused, not to say delighted, with the simple dignity with which such men as the Adamses, Franklin, Dickinson, and the great Virginia statesmen conducted the discussions, whether of matters of trade, of taxation, or of government.

«History, my Lord,» said Lord Chatham, in his famous address to the House of Lords, «has been my favorite study. . . . I must avow that in all my reading, and I have read Thucydides and have studied and admired the master states of the world, for solidity of reason, force of sagacity, and wisdom of conclusion, no nation or body of men can stand in preference to the General Congress at Philadelphia. The histories of Greece and Rome give us nothing equal to it.»

To this moment, indeed, no careful student of constitutional law or of the foundations of states can go forward in any intelligent inquiry without reading with care the work of the American statemen of that time.

It is interesting to observe that at the same time, perhaps from the same cause, the theological literature of America becomes less and less interesting. The mind and heart and soul and strength of the educated men of America was steadily drifting into an interest of the present relations between God and man and the present sway of the eternal law, much more important to men and women, and among the rest, of men of letters, than theological explanations of the secrets of the universe. The student of to-day finds it worth while to read the publications of Thomas Mayhew, of Boston, of Dr. Witherspoon, of Princeton, of Dr. Samuel Johnson, of New York. But this is not because he cares so much for what is called theology in its narrow definition, but because these men enter as champions of the people into that larger theology of men who really believe that they themselves and all men may be partakers of the divine nature.

Franklin with his genuine instinct for «Together» did not live long in Philadelphia without bringing together one and another club of men of inquiring disposition. One of these clubs still exists in the American Philosophical Society (q.v.). Another founded the fire department of Philadelphia. And, indeed, most of the activities which had given that city distinction, even before 1775, may be traced to such origins. Franklin's own newspaper, the ‘Evening Post,’ may be spoken of as really a literary journal. ‘Poor Richard's Almanac’ (q.v.) was not only an index of time and weather, but it was in its way a philosophical treatise. It was soon translated into French. Le Bonhomme Richard was known in French hamlets which knew nothing of the tea tax or the stamp tax. So soon as peace was declared such institutions as the American Academy of Arts and Sciences, as the Massachusetts Historical Society, as Tammany in New York, which was originally a scientific and philanthropic institution, came into being. The governors of the colleges took new courage; and Commencements and the celebrations which accompanied them gave good occasions for such appeals or lamentations with regard to an American literature, or the want of it, as gave a healthy stimulus to the literary life of the new nation.

A curious illustration of the increasing confidence in home and the literature of home, as years went by, would be found in the series of college addresses of which the first were published at Cambridge in 1796. The Phi Beta Kappa Society, founded in 1776 at William and Mary College in Virginia, soon outgrew its first limitations; and its annual exercises at Cambridge and New Haven were attended by graduate members who liked to renew their college

memories. Branches of it were founded in Brown College in Providence, in Dartmouth College in New Hampshire, and as years passed on, in other similar institutions. The early addresses by scholarly men in these societies were almost uniformly exhortation that the people of America might pay more attention to scholarship and literature. Meanwhile, and under such incentives, there grew up of course in one centre or another, small coteries of literary men and literary women. With an amusing regard to tradition such men seemed to have felt that there could be no literature without an epic or two on which it should be built. Timothy Dwight's 'Conquest of Canaan,' Joel Barlow's 'Columbiad,' which are all but forgotten, and several others which are forgotten, were the results, almost of a sense of duty in this regard. No one can suppose that either of these men was inspired by any divine inflatus of the poet. As you read the dreary lines you feel that the writer thought that there must be an epic and that because there must be he would write it, with the same feeling that a column of soldiers storms a redoubt. By the side of such men, however, there came to be naturally men and women who loved to clothe great thoughts or charming with fitting dress. There came, more and more, to such men and women, as there were, more and more readers to sympathize with them. And as popular education and wealth and leisure, and above all, freedom, brought upon the stage such men and women, the literature of America such as it is to-day was born.

It is interesting to see that almost all of the early books which we should now class as "efforts" in literature, were published by subscription. And there is something pathetic in the memoirs of the earlier literary men where they describe their personal visits from place to place as they solicited subscriptions to pay for the printing of their books. President Dwight himself visited the camp of Washington in 1775 and obtained the subscription of Washington and the other distinguished men around him for the publication of the 'Conquest of Canaan.' The reader must remember that the practical introduction of stereotyping in England or America is as late as the beginning of the 19th century. It was necessary, therefore, to test the market in some way when a book was first printed, so that the printer or publisher or author might know how many copies should be printed. It must be remembered, also, that the printers had no capital which would enable them to keep in type the cumbrous pages of a book which passed the size of a pamphlet. Paine's 'Common Sense,' in 1776, was probably the first book which attained at once a circulation in the least approaching the large editions of to-day. The trade, as the book-selling community still likes to call itself, now begins putting out as a feeler a small edition printed from stereotypes. In our day in a vault in the side of a mountain, or perhaps in a vault under a sidewalk we preserve such plates from which a book has been printed, and according as the demand may prove, new editions can be issued at a comparatively small expense. But up to the year 1813 there was no such resource.

A great publisher is on record as saying that when you have sold 5,000 copies of a book, you know you can sell 100,000. But that before the book is printed no man or woman can do more than guess whether it will have 1,000 readers or 1,000,000. There is a great truth hidden in this exaggeration. See AMERICAN PUBLISHING.

The pecuniary poverty of the printers of the end of the 18th and the beginning of the 19th century caused many American authors to go to England for the printing of their production. Barlow's 'Columbiad' was printed in England Irving's books appeared first in London. Indeed, Irving's wide reputation may be said to have been English before it was American. And he spent much of his early life in Europe, perhaps from the feeling that for a man of letters Europe was a home while America was a wilderness. James Fenimore Cooper made Europe his home for many years, feeling apparently that he could not find society of his own kind in his own land. The same is true of other American writers as far down as the thirties of the 19th century. That was the worse for the infant literature of the nation. Writers watched painfully for the expressions of English criticism, and one line from a Grub Street critic was sweeter to them and worth more than any words from their own countrymen. It is indeed impossible to overstate the effect which was eventually produced by the "American system," as it was called, in the discussions of tariff legislation which followed the short war with England. From the moment when the American printer could send out to the world books as well printed as the printers of England, one may trace new strength in American authorship. The International Copyright law of 1891 compels the publishers of all books which claim American copyright to print them in America. In a truly celebrated article in the 'Edinburgh Review' of 1820, of which no other line is remembered, Sydney Smith said, "Who reads an American book? who looks upon an American picture?" The men who painted American pictures were very mad, as their vernacular would say; and the men and women who wrote American books were equally mad. The writers had a better chance to express their anger than the painters. The sneer implied was the more cutting because for most purposes of literature it was true. Possibly it had some share in the growth, almost from that moment, of a literature which can fairly be called American. The worst of it was, perhaps, that Sydney Smith was in an advance guard of the Liberals of England. He could not be called the product of an "effete civilization," and his words could not be ascribed to Tory jealousy. American readers had known how to prize him and they read his articles if they did not read their own. But really an American author had little right to complain so long as Mr. Cooper called a woman a female simply because Walter Scott did, so long as our writers knew more of Robin-red-breasts and bulfinches than they knew of bluejays or mocking birds, so long as their best actors came from England as every play upon their stage was English, and so long as their scholarly men read the 'Edinburgh Review' and the 'London Quarterly' and the 'New Monthly Magazine' as they read no American journal. The American college boy knew much more of the loves and hates of literary men in England, one might almost say, than the English boy of the same time did.

The English reviews and magazines passed from hand to hand in the American reading rooms while their American rivals died a slow death due to the incompetency of most of the writers. But as the 19th century advanced the tide turned. Dr. Holmes in a happy phrase, quoted as often as Sydney Smith's which has been cited, fixes Emerson's first Phi Beta Kappa address as "our intellectual declaration of independence." I heard the address in 1837, and half a century afterward I heard his second Phi Beta address. Whoever will compare the two will see what Dr. Holmes means. To the thoughtful reader now it seems impossible that Emerson's first address should have seemed extravagant or in any way, indeed, out of the common to the men of that time. But it did seem so then.

It is true that ever since the century began such addresses on Commencement Days or on other literary occasions, have still given four fifths of the time to pathetic appeals to young men to create an American literature. The orators, generally, clergymen or lawyers, did not understand that such books as Lewis and Clark's journals were American literature, that Pitkin's statistics was a book of American literature, that Flint's 'Mississippi,' or Pike's 'Adventures' were vigorous bits of proper national literature, that the Constitution of the United States or John Adams' proposals for the State constitutions were American literature, as much as the Waverley Novels belong to Scotch literature, or Petrarch's 'Sonnets' to Italian literature. But by the middle of the 19th century, people had found out that literature is not a thing by itself to be worshipped and loved like some lonely classical statue in some separate shrine in a gallery, but that literature is simply the expression of what is. In the matter of American literature it proved that Americans had to state for the world the foundation principles of government. They had to describe for the world physical features of a continent of which the larger world knew nothing. And even the language in which they spoke would bear the marks of the climate, the soil, and the history of that continent. So soon as we throw aside the follies of talking about literature as literature and of worshipping it as a separate idol, so soon American literature can be spoken of as a thing in any sort distinct from the literature of the feudal system or other literature of the ancient world.

To review in the very briefest way the literary advance of the nation from the era of independence to the 9th of March 1904, we have to look first at the speeches and letters and pamphlets of the statesmen; and next at the reports of the explorers. There are individual poems and a few sporadic books in prose which linger in the remembrance of antiquaries,— Philip Frenau's Revolution poems, one or two sermons, perhaps may be classed among such memorials. To speak in a broader sense the first work of Irving stands as the first work in the large calendar of our modern literature. His amusing studies of early New York were known then, but the 'Sketch Book' as it was published in London in the years between 1820 and 1822 at once obtained a wide reputation, both in London and in America. Irving showed from the first that he could handle American subjects with a pen as light and a fancy as charming as gave life to Bracebridge Hall or his other English studies. In 1825, when Navarrete first published in Madrid the original documents of Columbus' voyage, Alexander H. Everett, who was then our Minister in Spain, called Irving's attention to these invaluable memoirs and suggested his work on the life of Columbus. Irving went at once to Madrid and was attached to the American Legation there while he studied the subject which is so closely identified with his name. And afterward, when the Spanish people received him as our Minister there, he enjoyed his well deserved fame. Here was an American who could meet English writers on their own terms. Irving was master as well as they of whatever is meant by style or method in literature, whatever secret of the guild there is.

In our time there is no longer a patron who shall endow a book as an emperor might endow an opera house at his capital. For a time or a nation without patrons, you must have such patronage of the public in advance as Dr. Dwight sought for with his subscription book; or, as it has proved, in 150 years, you must have magazines. This means, if one speaks to the Philistines, that you cannot have large wholesale business, no, and you cannot have manufactures unless there be retail business. Dr. Johnson and Oliver Goldsmith had found this out when they worked for Cave and the 'Gentleman's Magazine.' (See PERIODICAL LITERATURE.) One and another adventurer tried the magazine experiment in Boston, or Philadelphia or New York. But alas, the printers of the magazines were almost as poor as the authors were. The people of the country also were very poor in other affairs. As late as 1834 Dr. Holmes wrote for the 'New England Magazine' the first papers in the 'Autocrat of the Breakfast Table.' But the 'New England Magazine,' even with such contributors, died for want of readers. The new series of the Autocrat, in 1857, begins with the words, "As I was saying when you interrupted me," which referred to the death of the first series a quarter century before. Still, the names of those old magazines are interesting grave stones which show the roadway for a struggling national literature. The 'Harvard Register' of 1807 is one of the earliest. The Lyceum follows the Collegian, Harvardiana, and now almost every university gives this excellent field for the tournament of squires and even of pages who look forward to golden spurs of knighthood. A few lines of the Harvard 'Lyceum' of 1810 may be worth copying. They are from a clever parody of Barlow's 'Columbiad' and describe an early steamboat. They are among the boy amusements of Edward Everett.

So where high Hudson belts his hundred hills,
Winds his wide wave, and York's broad bason fills:
With engine force the fluid fields to plough,
The mighty Steam-boat points his sailless prow.
Knees from the winds no gales, the sea no tides,
Whirls the wheel oar, and o'er the river rides.
Lo with what art the nice machinery turns,
With what fierce force the pitchy pine pole burns.
See the black Boiler, in whose darksome womb,
The prison'd water vapours into fume:
The hollow Cylinder, whose shining side
Cramps the crook'd Chain, and turns the densing tide:
Etc., etc., etc.

Of those of the magazines proper which were manfully and loyally sustained for many years is the 'Knickerbocker' which was published in New York monthly for several years. Most

of the authors who won distinction in the literature of the century made their maiden contributions to its pages. In Boston a beginning, which proved to be a foundation, was made in the issue of the 'Monthly Anthology,' of which the first number was printed in 1809. It was the work of a literary club, and it is very creditable to the literary life of the day. Some original translations from the minor poems of the great German poets slipped in. And by this time, America had found out the resources of the German colleges. George Bancroft, Frederick Hedge, Edward Everett, Henry F. Quitman, George Ticknor studied in the German colleges. The success of the 'Anthology' and perhaps a certain jealousy of the literary tyranny of the 'London Quarterly' and the 'Edinburgh Review' led William Tudor, with the spirited young fellows who wrote for the 'Anthology,' to announce the 'North American Review' of which the first number was published in 1815. It may be said of the 'North American Review' that a desire to imitate the English quarterlies weakened it for perhaps a quarter of a century. But its tone was always dignified and on really national questions it was American. In the earlier numbers of the 'Review' it admitted poetry and some short articles which did not pretend to be criticism of books. The successive editors of the 'Review' were William Tudor, Edward Tyrrel Channing, Edward Everett, Jared Sparks, John G. Palfrey, Francis Bowen, Andrew Preston Peabody and Alexander Everett, and James Russell Lowell. A few years after the Civil War it was removed from Boston to New York under the direction and charge of Allen Thorndike Rice. In Philadelphia what was called the 'American Quarterly Review' was published under similar auspices.

Meanwhile what had attracted attention at once to a very great extent was the success of Cooper's novels. The later novels of Scott were still engaging the attention of readers when Cooper's earlier stories were published. He had left Yale College without a degree, disgusted with something or other as youngsters are apt to be in colleges, and had joined the United States navy. This as it proved, was fortunate for the literature of America. After the short war with England, he was stationed on Lake Ontario, which was at that time in the wilderness. At his father's home he had already made acquaintance with the wrecks of the Six Nation Indians (q.v.). At Oswego he fell in somehow with the last of the Mohicans. His study of a real forest and his studies of the forecastle of American ships are both genuinely national, and although he could not resist the spell of the "great enchanter," and imitated Sir Walter Scott whenever he got a chance, the early Cooper novels have the great charm of being interesting. To this hour the school boy reads them as his grandfather read them and regards them among his best friends. In Cooper's later novels there may be seen a tinge of ill temper because he fancied that he had not been esteemed fairly by his own countrymen. But the early novels have established themselves in a well assured place in the literature of his country. Few people remember them, but it is said that the German novels on American subjects by Sealsfield (q.v.) were the inducement for a time of the great German emigration which began as soon as these spirited books began to be printed. His German name was Karl Postel.

Meanwhile the leaders of the nation had found out that a republic stands or falls according to the education of its people. It is impossible to estimate the change produced by the early determination of the more civilized States to improve the education of every child born in their borders. At the beginning of the century you might say that there was nobody to buy books, even if angels or archangels had descended from heaven to write them. But even in the middle of the century an army of readers, men and women, had been created. It began to be evident that a good book in the English language had more readers in America than it had in England. It began to appear that the reputations of English writers depended quite as much upon the American readers as upon those of the British Islands. Scott, Byron, Wordsworth, Coleridge, and Southey, had more readers on this side of the ocean than on their own. The same was true later of Macaulay's 'History' and of other books of permanent value. Disraeli said as early as 1845 that America was the present posterity for the Englishman,— that an English author knew what posterity would think of him by learning what the American of to-day thought of him. The creation of such a body of readers led to the growth of a genuine American demand for what could be called an American literature. A school of history grew up first in which Irving had led the way in which the great historical addresses of Webster and the Everetts and other orators were an essential part. The subserviency to English critics diminished as more and more scholars came from France and Germany. It would be fair to say that Bancroft, Prescott and Motley, as historians, Emerson as a philosopher, Longfellow, Lowell, Holmes, and Whittier as poets, made a distinct American school after the year 1830 when Bancroft announced his plan for his history, or more definitely perhaps in 1833. So far as this was a New England school it was somewhat affected by the literature of the Continent of Europe, but this effect has been overstated. Emerson was not at all indebted to Germany in his work. Longfellow's poems are distinctly American when they are not translations. Lowell won his English reputation by the admirably national characteristics of the Biglow Papers. Still a distinct ripple on the tide of literary advance may be found in all the seaboard States when in the twenties of the last century, the Holy Alliance (q.v.) exiled from Germany Lieber, Follen, Beck, and some other young students who had displeased Metternich.

What is familiarly called the Lyceum System introduced an element of value constantly increasing in the higher education. It ought to be remembered that the Lyceum introduced Ralph Waldo Emerson to the people of America in a much shorter time perhaps than any published writing would have done without its assistance. Where the trustees and faculties of colleges would have refused to invite Mr. Emerson to speak, the students of college societies would gladly send him an invitation. Once heard he was of course sure to be remembered. Not to speak of other lecturers who were instructing all the northern states, arousing curiosity as to subjects on which they hardly touched, Ralph Waldo Emerson when he took up the

work of a prophet unlimited by the restrictions of the priesthood led the way in a revelation which has affected all the literature of his time, whether in America or in England. In the smaller New England circle, Margaret Fuller, afterward the Countess Ossoli, by "conversations" and published essays called the attention of many young people to the wider realms of thought and especially to the more modern movements of philosophy and literature.

With the existence of a sufficient body of readers large circulations became possible for magazines. The first which succeeded pecuniarily were those who told the most stories, and it was on the basis of story telling that the 'Southern Literary Magazine,' 'Graham's Magazine,' the 'Godey's Ladies' Book,' and the 'Boston Miscellany of Literature and Fashion' came into being and by their success with the public created the literary magazine of to-day. When a Boston publisher could say in 1841, "We sell 1,000 copies every month to the Lowell factory girls," the word was spoken which showed that a sufficient supply of readers is necessary in the creation of a literature, and will in its time bring into being a sufficient number of writers. The 'Knickerbocker,' the 'New England Magazine,' and the 'Port-Folio' had failed to enlist anything like the public support which waited on all decent magazine work after the public schools had created their army of readers. One and another ineffectual effort was made to turn away the current of the English magazines and to introduce an American circulation in its stead. It is interesting to see that the early numbers of 'Harper' were written almost wholly by English writers and large editions of 'Fraser's Magazine,' of the 'Dublin University Magazine,' and of 'Blackwood' still made up the popular reading of the reading rooms. But in 1857 the 'Atlantic Monthly' was created with such writers as Bancroft, Prescott, Motley, Holmes, Lowell, and Longfellow among its very earliest contributors, and one may say, on its working staff. Lowell was an office editor of the 'Atlantic.' 'Putnam's Magazine,' in New York, sprang full armed into existence It introduced itself by an article which awakened curiosity, and perhaps one may say national pride, on the question, "Have we a Bourbon among us?" From that day to this, magazine literature has held an important part in the work of the better literary men of America.

The short story had been invented in England. The serial story as Dickens and Thackeray had shown, gave admirable opportunities for feeling the public pulse. It is amusing today to read that the publishers of the 'Anti-slavery Standard' doubted whether they should pay James Lowell $400 a year for his contributions to that journal, contributions among which are some of the best poems which he ever wrote. This is only one among the many illustrations which peep out from the books of biography as to what Dr. Johnson or Goldsmith would have called the patronage of the readers of magazines and their editors. The encouragement to authors was little but it was enough. In the year 1849-50 the people who read anti-slavery newspapers began to talk of the serial issues in which the story of 'Uncle Tom's Cabin' was going forward in a newspaper called 'The National Era.' The southern writers on the Civil War ascribe to that book the complete change in American politics and in the questions which led to the war which belongs to the middle of the century. In 1851 the story was published in book form and at once became known not simply in America but in England and in all the literature of the civilized world by means of translations. Its circulation in England, for instance, was the first circulation of a book on what was called popular prices. One edition of it appeared in a newspaper issue at the cost of one penny a copy. Mrs. Stowe's supremacy as a writer of fiction established itself at once and from that moment to this, American literature can make the boast that it has furnished the book of which more copies have been printed than of any other book which originated in the English language. It is a little curious that its only possible rival, if one considers simply the number of copies printed, is 'Robinson Crusoe.' Mrs. Stowe's story is that of a fugitive slave; Defoe's story is that of a shipwrecked slave trader. Since the issue of 'Uncle Tom's Cabin' no American writer has cared to show his acquaintance with the etiquettes of marquises and dukes. The temptations of travel give to the American readers every now and then a good book as where 'Daisy Miller' takes them by night into the Coliseum, or when husband and wife stray together in the gardens of a German watering place. But no American writer selects a European scene from any wish to work for the sympathies of European readers. On our own continent our historians find their themes, our novelists their interests. With the Civil War the dependence upon English criticism and the respect for it died in a night. Up till that time, young America had permitted the distance of the writer to be warrant for his education and his judgment. At that time in the nation's struggle for its existence, it received no sympathy from the writers of England. They had been trained under feudal institutions and they were glad and pleased that democratic institutions were to fail. The young men and women of America learned that for the criticism or for the education which belonged to this nation, they must study their own country. In truth the society of America is American society, the laws of America are American laws. Its prospects and hopes are those of a democracy. As the strata of its rocks and the growth of its trees are different from those of England, so are the foundations of the state and the customs of its administration. It is impossible here to consider in the least detail the methods of different writers who have won the love and admiration of their countrymen in the years which have followed.

The central observation is that as soon as America furnished readers enough a proper American literature followed the demand. As soon as the system of the country made possible first-rate printing offices in rivalry with the best printing houses in England, the American demand for American books could be answered at home. In naming Cooper and Irving we have named the two writers distinctly American whose published work was first everywhere known. Other authors printed their books which were forgotten. There was perhaps something ludicrous in the effort to create aboriginal enthusiasms which did not exist. For instance, any early copy of the 'North American Review'

will show the standing advertisement on the cover that the publishers had a "supply of the 'Yamoyden' kept constantly on hand." The 'Yamoyden' was a poem on a supposed hero or heroine of Algonquin origin named the "Yamoyden." But the publishers spoke of the volume as a commission house might speak of so many bushels of wheat or of barley. Books or essays of purely American type struggled into existence and some of them are still remembered. Edgar Allan Poe was born in the year 1809 and died in the year 1849. Warren Burton's 'District School,' Mrs. Gilman's 'New England Housekeeper,' some of James K. Paulding's sketches and essays were distinctly American. Mrs. Sedgwick and Miss Sedgwick wrote admirable and unaffected books. Edward Everett and Alexander H. Everett with all the advantages of early European training were thoroughly American in their orations and in the work which they did in the 'North American Review.' That 'Review' itself while it imitated aspects of the English quarterlies always carried an American chip on the shoulder and defied all foreign travelers or foreign critics who did not find perfection in everything American. A story of pure American life, most instructive to the student of that older time is Sylvester Judd's story of 'Margaret, a Tale of the Real and Ideal, Blight and Bloom.' Judd was a poet, but this prose novel has proved his best work.

The exquisite genius of Nathaniel Hawthorne would have worked its way through any difficulties. In his own nation his favorite earlier subjects drawn so largely from the traditions of the early centuries, undoubtedly had their share in introducing him to the great body of readers. So soon as he traveled abroad, he showed that he could handle any traditions and was at home in any atmosphere. As in all work of men of genius his temperament and as he says, the traditions of his life, governed to a certain extent his choice of subject. But always it is Hawthorne who is the master and fascinates the reader; and there is no other Hawthorne. In other instances perhaps a certain charm is given in English circles to the naivete of what one may call the frontier habit of the American writer. Walt Whitman had an affectation of expressing a disgust which he did not really feel with all the conventionalities and institutions which did not smell of the pine knot or of kerosine. He is said to be better known in England than in America. This is somewhat as it has happened with an American preacher like Moody and others who could be named, who has won attention even by the accent of his voice. After he had won attention abroad he needed nothing more. We may say again that this is no place to enter into an analysis or other discussion of the work of different American authors and of their hold upon the national life. When one remembers that no prose writer of our country is more likely to be generally read three centuries hence than the despatches of Ulysses Simpson Grant, he hesitates before he shall say who are the literary men. Give time enough and Washington becomes a literary man, and Judge Marshall. But this may be said, that of the 29 heroes in the New York Hall of Fame, Thomas Jefferson, James Kent, Joseph Story, Asa Gray, Jonathan Edwards, William Ellery Channing, Horace Mann, Henry Ward Beecher, Ralph Waldo Emerson, Nathaniel Hawthorne, Henry Wadsworth Longfellow, and Washington Irving, would not have been named among the most distinguished Americans except for their work with the pen. Franklin might be numbered as a naturalist, Washington or Grant as soldiers; but the 12 who have been named won their place simply as authors. And every one who is in any way familiar with their work understands that this work is distinctly American. You could not mistake it. If you read 25 pages from any of these authors, you would know that he was brought up under the institutions of a Republic and that the width of horizon, may one say, comes in as a part of the atmosphere to which in the omnipotence of God the American is accustomed. In naming those to whom the country owes the growth of its literary taste, the charm of great travelers and great historians should be added to the great statesmen. But the list as far as it goes is not useless, for it shows what is the current of average feeling of the people of America. The people of America is sovereign of America and as everywhere the sovereign is the fountain of honor. We could choose no better instance of the encouragement given by the people to the author of first-rate genius and ability than is found in the literary career of John Fiske. Fiske owed none of his success to official position. No distinguished review called attention to the way a young man needed encouragement, but simply Fiske had a great deal to say and he said it. And by the time he said it there was a nation of people who had been educated to appreciate and enjoy what he said. He used to say that even in his young life he was looking forward to history as the study which he was to pursue through his life. The opportunity came for the gratification of this passion. He seized upon the opportunity, and the American people recognized the hand of a master. But Fiske was not to be shut up within any narrow range of study or of authorship. He had his own views of life and duty, of ethics and of destiny, and he wrote them down. He said what he wanted to say in a form which won the sympathy of all thoughtful people, and there were enough readers trained to careful thought to welcome the gifts which in such service he made to the nation. Perhaps in speaking of this instance we are speaking simply of the step forward which the conscience and heart of the whole nation made in obedience to the word of Ralph Waldo Emerson, who gained a welcome in all quarters,— in the miner's cabin or in the sanctum of kiln-dried seminaries. It has been said that of the early volumes of Emerson's 'Essays' millions of copies might be found to-day in the hands of the most ignorant or the most learned men and millions of men who never heard his name are living under the inspiration of his prophecies. It is said by the English critics that Mr. Longfellow's poems are better known by the people of England than are Lord Tennyson's. Perhaps this is true.

It has also been curiously true that more than one English reputation has been first made in America. Carlyle's first books were well known here before the critics of Eng-

land honored them with their approval. The English writers whined a good deal so long as they had no protection at American law for their copyrights. This nation was creating a reading class at an expense such as monarchs never dreamed of, such as England has never thought of, and it was the fashion to chide Americans because at the outset they did not throw open the market thus created to the writers of a nation where there was not one reader for a hundred in America. The International Copyright Act has remedied this grievance. But it has not proved that either the English or American author has gained readers by any of the accidents of publication. The rule holds which Abraham Lincoln laid down so well that the people who like that sort of thing will read that sort of thing. But so far as statistics of the trade in books go, it is evident that the rank and file of American readers are interested in American subjects treated by writers who feel the American impulse and were early baptized in the ways of democracy. It is more necessary to say this in this article because so much of the less important writing for the American daily press of this century is from the pens of men who are educated in the British Islands or on the Continent of Europe. Such men do not fully understand the spirit of the life in which they live and necessarily treat its questions as foreigners.

Of writers now living it is hardly becoming to speak in these pages. The first novelist of this generation born in Ohio, cradled in the midst of the matchless resources of that empire State, still lives young and vigorous, to delight the readers of the English language in all parts of the world. He has occasionally toyed with European scenery and experience, but his work is the work of a true democrat trained to know that men live for each other and in the 20th century each man has to live for each and each for all. After you cross the Mississippi River, when you buy your morning newspaper, the chances are that you find no reference in it to any lands on the eastern side of the Atlantic or the western side of the Pacific. The journalists of that region also have their affectation which compels them to leave Europe and Asia disregarded as they might disregard the governments of Sesostris or of Nebuchadnezzar. For even the names of the leading writers of to-day, whose works are far too numerous to be catalogued here, we must refer the reader to those names separately as they will appear on different pages of this encyclopedia.

Edward Everett Hale,
Author of 'The Man Without a Country.'

American Manufactures. The 12th census marked the close of the first complete century of manufactures in the United States. It thus became the most important statistical basis by which to measure the future advancement of American industry. It was with these words that the final report of the 12th census on manufactures began. It might have been added that the 12th census is the first to occur since the United States has become distinctly a manufacturing nation and has produced a surplus of manufactured goods with which it has entered the world's trade to acquire foreign markets.

History.— In 1791, when Alexander Hamilton submitted his celebrated "Report on Manufactures" to Congress, he was able to refer to the household system of manufacture by means of which each family unit supplied many of its own needs; and he described the remarkable development of this type of manufacture in southern New England, where considerable quantities of coarse cloth, clothing, and nails were produced. In addition to this, some twenty industries were mentioned which had reached a considerable development, involving special buildings, the division of labor, the ingathering of raw materials from distant localities, and the distribution of the manufactured articles throughout the States.

While this was a respectable beginning, the chief task of the American people for at least five decades was to push forward the frontier. Up to 1840 this work went on. By that time compact settlement had reached the Mississippi River, and the further growth of population required the building of railways and the establishment of manufactures. By 1850 the chief forms of labor-saving agricultural implements of American origin were introduced and began their work of liberating an increasing proportion of the population from agriculture. The Civil War increased the need of the country for manufactured articles, and, accompanied as it was by a high tariff to provide government revenue, provided a powerful impulse to develop home manufactures. Down to 1880 agriculture was the chief source of wealth in this country. The last two censuses have shown manufacture to be dominant. In 1900 the value of agricultural products was $4,700,000,000; the net value of manufactured products was $5,900,000,000.

We may group our industrial history into periods, therefore, roughly as follows:

1609—1789	Colonial period.
1790—1840	Period of western settlement. Agriculture for home consumption except cotton.
1840—1880	Period of agricultural dominance. Large export of raw materials.
1880—1900	Dominance of manufactures for home use.
1900—	Period of foreign trade in manufactures as well as raw materials.

General Comparisons.— To gather some of the chief results of the recent census investigation into a few sentences we may say that when we speak of "American manufactures" we mean 512,339 establishments, using $9,835,086,909 of capital, and involving the labor of 397,174 officials and clerks and 5,316,802 wage-earners. This vast equipment consumes $7,348,144,755 worth of raw materials annually and makes out of the same manufactured products worth altogether $13,014,287,498. These figures all show a healthy increase over those of 1890. There are 44 per cent more establishments now than then; 50 per cent more capital is used; a fourth more wage-earners are employed; and the annual value of the gross product is 40 per cent more than in 1890.

In 1810 the manufactured goods produced in this country were worth $27.58 per capita of the population, or $165.48 for the average family. In 1860 manufactures were worth $60.06 per capita, or $318.32 for the average-sized family of that period. In 1800 the per capita value was $149.72, or, for a family of 4.9 persons, $733.63. In 1900 the per capita value of manu-

factured goods was $172.21, or $809.39 for the average family of 4.7 persons.

Classification of Establishments.— There are three ways in which manufacturing establishments may be classified:

1. According to the general economic class to which they belong.

The 512,254 establishments considered by the census as "manufacturing establishments," in the strict meaning of the term, are divided into:

Household industries and repairing	215,810
Manufacturing — other	296,444
To these we may add small establishments producing annually goods valued at less than $500.	127,419
Government establishments	138
Educational, charitable and penal establishments.	383

2. The second classification of establishments is according to the form of organization employed. It is as follows:

Individual ownership	372,703
Partnership	96,715
Company or corporation	40,743
Co-operative association	1,765
Miscellaneous	174

The corporation is the form in which the larger businesses are usually organized, and controls 59.5 per cent of the product. Co-operative associations are confined to the manufacture of butter, cheese, and condensed milk.

3. The third classification is according to industry. The 12th census has given us for the first time a carefully digested grouping of manufactures, as follows:

(1) Food and kindred products, (2) textiles, (3) iron and steel, (4) lumber, (5) leather, (6) paper and printing, (7) liquor and beverages, (8) chemicals, (9) clay, glass, and stone, (10) metals other than iron and steel, (11) tobacco, (12) vehicles for land use, (13) ship-building, (14) miscellaneous, (15) hand trades. Of these classes the most numerous, excepting the hand trades, is the first, "food and kindred products," with 61,302 establishments. The least numerous is that of ship-building, in which there are 1,116.

The Manufacturing Population.— The statistics show that 29,000,000 persons over 10 years of age are engaged in productive industry. A little over a third of these are in agriculture, a fifth are in domestic and personal service, a fifth are in trade and transportation (16.4 per cent) and the professions (4.3 per cent) combined, and a fourth are in manufactures and the mechanical pursuits, including mining.

To this latter fourth belong the 5,713,976 persons engaged in manufacture. In the last 20 years the number of persons in professions, trade, transportation, and manufacture has increased relatively. The number of persons in agriculture has decreased relatively. The domestic and personal service class has remained constant.

The proportion of men, women, and children in manufacturing establishments is such that if a given establishment employing 100 persons desired the typical division of men, women, and children, it would be obliged to employ 77 men over 16 years of age, 20 women over 16 years of age, and three children under 16.

Power.— Half of our manufacturing institutions use power of some sort to supplement hand labor. So liberally and skilfully is power used in the United States that the average output per employee is between three and five times what it is in England. The most prominent fact in the evolution of sources and forms of power is the increase in the use of electricity.

Growth of Large Establishments.— The census shows the increase in the size of plants by showing that, while the product of manufacture has been increasing in almost all lines, the number of establishments has been declining in many of them. There was in 1900 a smaller number of establishments than in 1890 manufacturing agricultural implements, boots and shoes, carpets, glass, iron and steel, leather, woolens, and the products of slaughtering and meat-packing; nevertheless in each of these industries the average capital, the average number of employees, and the average product per establishment increased, and the total product of each of these industries increased.

A more direct but not more positive proof of this tendency is shown by the enumeration of large establishments. In 1900 there were 452 plants in each of which over 1,000 employees worked. Of these 120 were in textile manufacture (one in New Hampshire employing 7,268 persons), 103 were in iron and steel manufacture (one in Ohio having 7,477 persons), 48 were in vehicle manufacture, 29 in food products, 20 in metals other than iron and steel, and 132 in miscellaneous lines.

Turning to the question of industrial combinations we find some interesting statistics in the census. A list of 185 such organizations is presented. They controlled 2,040 plants, possessed a combined capital of $1,436,625,910, employed 400,000 wage-earners and 24,640 officials, and manufactured products annually valued at $1,667,350,949. That is to say, 8.4 per cent of the wage-earners engaged in manufacturing in America were employed by these combinations, and 14.1 per cent of the value of our manufactures originated with them. The census report does not include the United States Steel Corporation or any other combination organized during or since the census year. The steel corporation is largely covered by the above figures, however, since most of its constituent companies rank as combinations. The great dividend-payers among the "trusts" in 1900 were the Standard Oil Company, American Steel and Wire Company, Federal Steel Company, American Sugar Refining Company, Amalgamated Copper Company, Pullman Company, American Tobacco Company, Continental Tobacco Company, and the United States Leather Company.

Localization of Manufactures.— The industries of the United States are generally strongly localized in certain regions. This tendency to develop a territorial division of labor has always been marked in this country, in agriculture as well as in manufactures. The causes which lead to the location of industry in certain places are enumerated by the census:

1. *Nearness to Materials.*— This is illustrated by the oyster-canning of Baltimore.

2. *Nearness to Market.*— The agricultural implement manufacturers of Chicago find their best market in the region which is tributary to that city.

3. *Water Power.*— Fall River, Mass., with its textile manufacture, Cohoes, N. Y., with its

knitting industry, and Niagara Falls, with its electro-chemical industries, have resulted from the utilization of water-power.

4. *Favorable Climate.*— The Piedmont section of the South attracts cotton mills, not only because of its nearness to materials and its water-powers, but because of its favorable climate.

5. *Supply of Labor.*— The garment trades are largely monopolized by New York, Philadelphia, and other large cities on the coast, because there a large population of foreign birth, with low standards of living, furnish adequate supplies of cheap labor.

6. *Capital Available for Investment in Manufacture.*— When the whaling industry declined, New Bedford, which had become wealthy by means of it and was ranked as one of the richest cities in the United States, put considerable of its capital into cotton manufacturing. The city of Chicago was not able to surpass Cincinnati as the centre of the pork-packing industry in the West until the local banks acquired enough money to aid the packers in carrying the enormous financial load of buying the raw materials, which for that business constitutes about 75 per cent of the value of the finished product.

7. *Momentum of an Early Start.*— Sir William Johnston early brought glovers from England to Johnstown, N. Y., and started the industry for which that city and Amsterdam and Gloversville are now noted. Had the celebrated "shoemaker of Lynn" settled in a neighboring village, Lynn might not now signify shoes wherever the name is heard.

If we examine a map showing the location of American manufactures we shall observe that they are markedly concentrated along the Atlantic seaboard, from the middle of Maine to the latitude of Baltimore, and covering a region extending perhaps 100 miles back from the coast. West of this an irregular belt of country, including middle New York, western Pennsylvania, and northeastern Ohio, stands out prominently. Passing still farther west we find the manufactures not so evenly distributed, but rather concentrated at certain points, such as Cincinnati, Louisville, the gas belt of Indiana, Chicago, Milwaukee, St. Louis, Minneapolis, Kansas City, and Omaha. The South shows a large number of small, rather isolated manufacturing localities. These occur most frequently upon the Piedmont plateau, from southern Virginia to northern Alabama. In the Rocky Mountain States and the region west of them, five centres stand out separated from one another by wide intervals of undeveloped country. They are the middle portion of Colorado, Salt Lake valley, the Butte region of Montana, the Puget Sound and Columbia River cities, and San Francisco, with the adjacent cities from Sacramento to Alameda.

The national centre of manufactures has been fixed at a point east of the middle of Ohio, about 25 miles southeast of Mansfield. It has moved west only about 40 miles in 10 years. The centre of population lies 200 miles southwest of this, at a point about 8 miles from Columbus, Ind.

California is first in preserving vegetables and fruits, vinous liquors, lead smelting and refining.

Connecticut is first in ammunition, brassware, clocks, corsets, cutlery, needles and pins, and hardware.

New York is first in 31 industries, among which are butter and cheese, gloves, factory-made clothing, furniture, chemicals, hosiery, malt liquors, lithographing, printing and publishing, millinery and lace goods, paper and pulp, patent medicines, soap and candles, sugar refining, cigars and cigarettes.

Illinois is first in the manufacture of agricultural implements, bicycles, cars, glucose, and distilled liquors, and in slaughtering and meat-packing.

Wisconsin is first in lumber and timber products.

Minnesota leads in flouring and grist-mills.

Texas leads in cotton-ginning and the manufacture of products from cotton-seed.

Some manufactures are limited to very restricted areas, a group of States or a single State or even a portion of a State confining them. The most highly concentrated industry is the making of collars and cuffs, of which 99.6 per cent is within New York State and 85.3 per cent is in the single city of Troy.

The tendency to centralize industry has given rise to cities which are chiefly devoted to one occupation. The city most wholly given up to one thing is South Omaha: 89.9 per cent of the products of this city are the output of the great packing houses located there. A list of cities of 20,000 and over in population, in each of which 40 per cent or over of the industrial products belong to one branch of manufacture, is as follows:

Shoes — Brockton, Haverhill, and Lynn, Mass.

Agricultural Implements — Springfield, Ohio.

Collars and Cuffs — Troy, N. Y.

Cotton Goods — Warwick, R. I., Fall River, and New Bedford, Mass., Lewiston, Me., Manchester, N. H.

Fur Hats — Bethel and Danbury, Conn., Orange, N. J.

Glass — Millville, N. J., Tarentum and Charleroi, Pa.

Knit Goods — Cohoes, N. Y.

Iron — Youngstown, Ohio, McKeesport, Johnstown, New Castle, and Pittsburg, Pa., Joliet, Ill., Trenton, N. J.

Jewelry — North Attleboro and Attleboro, Mass.

Gloves — Gloversville and Johnstown, N. Y.

Pottery — East Liverpool, Ohio.

Silk — West Hoboken and Paterson, N. J.

Slaughtering and Meat-packing — South Omaha, Kansas City, Kan., St. Joseph, Mo.

Cities.— About one half of the manufactures of the United States are turned out in our 100 largest cities. These cities contain 23 per cent of the population. About two thirds of these products come from the 209 cities having over 20,000 population. The greatest concentration of a manufacture in cities is found in the case of men's and women's clothing, hats and caps, cars, umbrellas and canes, lithographing and engraving. The smallest degree of concentration is found in the case of flour- and grist-mills, distilled liquors, and brick and tile.

New York city is most cosmopolitan in its manufactures, exhibiting the greatest variety of

them, and having a number of establishments which are the only ones of their kind in the country. In 1900 there were 39,776 manufactories in New York city, employing $9,250,000 capital and 500,000 persons, turning out goods annually to the value of $1,371,000,000. The most numerous class of establishments in the city was for custom work and repairing of boots and shoes, of which there were 3,341. There were more than 1,000 establishments each for the manufacture of cigars, women's clothing, dressmaking, carpentering, men's clothing, and also for plumbing, painting, and blacksmithing. There was only one establishment each for the manufacture of bells, felt goods, firearms, leather-board, and car-fare registers.

Achievements and the Outlook.— The general causes which have made us a great manufacturing nation, and the advantages which we now possess, have been placed under five headings:

1. *Agricultural Resources.*

2. *Mineral Resources.*— It is plain that a country which produces nine tenths of the world's cotton, one third of its coal, one fourth of its iron ore, and one half of its copper, and a similar generous share of many other things, such as lumber, grain, hides, and petroleum, has a great advantage in the matter of raw materials upon which to set labor and capital at work.

3. *Transportation Facilities.*— These include the remnants of a neglected canal system, a magnificent but scarcely used system of navigable rivers, amounting to 18,000 miles, and a highly important system of Great Lakes, waterways extending for 1,000 miles and carrying a tonnage "equal to nearly 40 per cent of that of the entire railway system of the United States." Our railway system, constructed with great rapidity between 1860 and 1880, is now over a third of that of the world. In 1899 the total length was 189,295 miles, as against 172,621 in Europe, and the cost of moving goods was less here than in Europe, being on the average less than six mills for carrying one ton a distance of one mile.

4. *Freedom of interstate commerce.*

5. *Freedom from tradition.*

As an example of American ingenuity we may cite the invention of the system of interchangeable parts, which has made possible the use of complex machinery in agriculture or other industries at a distance from machine shops or the point of original manufacture. Activity, skill, and willingness characterize the best type of American workmen, and this willingness is shown in part by a readiness to pack bag and baggage and move to those places where manufacture can be carried on most economically, especially if it be to a large city. The organizing ability of American capitalists cannot be doubted. There is scarcely an industry upon which the peculiar genius of the American has not wrought an effect.

In food manufacture we began with the slowly revolving millstone, but Oliver Evans originated the system of automatic conveyors now in use. When later this was coupled with the middlings purifier, also of American origin, and the Hungarian roller process in a modified form, the modern mill first became a reality. Here the factory system was first applied to the making of cheese and butter, resulting in the cheese factory and creamery. An instance of a wonderful application of machinery to a complex process is afforded by our slaughtering- and meat-packing establishments.

In textile manufacture we are now the second nation in the world in the number of cotton spindles operated, and first in the amount of cotton fibre used.

In iron and steel manufacture we have passed our chief rival, Great Britain, several years since, and now English ironmasters who visit us say that nowhere in the world are labor-saving devices so masterfully designed and employed as here. In the using of steel we are quite as original. To this the heavy rolling-stock, rails, and bridges of American railways testify. Here structural steel was first employed in buildings. The structures into which the first girders went are still standing — Cooper Union and Harper's publishing house in New York city. An enormous demand for iron and steel is created for agricultural and mining and manufacturing machinery, and also for electrical equipments and gas and water pipe. Nowhere are stoves and ranges made so large and beautiful as here, and nowhere is tin-plate used so lavishly. In lumber, leather, paper, and other lines the record is similarly encouraging.

University of Michigan.

American Mathematical Society, an association established in 1888 as a local organization in New York, and reorganized in 1894 under its present name, to encourage an active interest in mathematical science. Membership 400.

American Medical Association, a society organized in 1847 to foster the growth and diffusion of medical knowledge. Membership upward of 12,000. Its chief publication is the 'Journal' of the association. Office of secretary, Chicago, Ill.

American Merchant Marine, The. International commerce and communication between nations by means of ships have always been prominent factors in the development and growth of a nation, and by their relative importance at any period, the power and position of a country among states may be estimated. The growth of the mercantile marine of the United States after independence had been declared and after the War of 1812 affords ample demonstration of this fact, as also does the decadence that ensued consequent on the Civil War, and contributory causes, the declining point of which is definitely located in the decade between 1855–65. Prior to this latter period, and following on Jay's treaty of 1794 (q.v.), the mercantile marine of the United States developed at a conspicuous rate. With the exception of the United Kingdom and her colonies, this country possessed the greatest number of ships and the largest amount of tonnage among the nations of the world, and gave evidence at one time of a likelihood of surpassing Great Britain in becoming the most extensive carrier on the universal ocean. Statistics show that in 1859, 66.9 per cent. of the foreign commerce of the United States in imports and exports was carried in American vessels. Six years later, after the Civil War, this had been reduced to

THE OLD-TIME WOODEN SHIP.

THE MODERN IRON SHIP.

27.5 per cent., and gradually decreased until in 1901, it reached 8.2 per cent., since when there has been an increase to 10.3 per cent. in 1904. From second position, the United States had come to rank third after Germany among the mercantile powers of the world; in marine tonnage being surpassed three to one, and on the ocean nine to one, by Great Britain.

While compensation is found in the marvellous internal progress of the country, the development of the American merchant marine also exhibits, besides ordinary material growth, interesting phases which are worthy of examination before detailing in outline the carrying trade of the United States prior to the Civil War, and its subsequent decadence for which various measures of relief have been recommended. Before and during the American Revolution the international struggle for the mastery of the seas precluded any possibility of freedom of trade, and one of the greatest opponents to the development of any foreign merchant marine than her own was Great Britain, now in the first decade of the 20th century, with the United States and Japan the foremost champions of the principle of the "open door" to the whole trade of the world, and of freedom and noninterference in commercial affairs. In maritime relations, Great Britain was still governed by the navigation laws of the 16th century, which had been formulated again Dutch expansion and commerce, while generally similar discriminating and retaliatory measures were in force among European maritime nations against rival merchant marines. Of this nature, illustrating the conditions of international commercial jurisprudence at the beginning of the 19th century, were the Orders in Council, directed against France and the counter attack of Napoleon with the Milan decree. Great Britain's claim of the right of search and impressment, and the refusal of the United States to recognize that right, was one of the causes of the War of 1812, and the opposition of the United States undoubtedly inaugurated the era of oceanic commercial freedom, together with the doctrines of free ports and open doors, adopted and fostered later by Great Britain and so successfully promulgated in the case of China during the Boxer agitation of 1900-01 and the Russo-Japanese war of 1904-05 by the late United States Secretary of State John Hay. Great Britain materially assisted, although unwittingly, in sustaining the principle of the freedom of the merchant marine, when protesting, during the Civil War, against the forcible action of Captain Wilkes of the United States ship *San Jacinto* in boarding and searching the British steamer *Trent* for the Confederate commissioners James Murray Mason and John Slidell who were made prisoners. Secretary of State Seward and President Lincoln gracefully acceded, although against public opinion, to releasing the prisoners, and in so doing admitted that the United States had no right to search a British vessel, and *per contra* Great Britain was deprived of the weapons of search and impressment which, by *force majeure*, she had so long wielded against weaker nations.

Meanwhile the introduction of steam and the great advances in all branches of engineering during the 19th century had contributed largely to the development of the merchant marines of the world, firstly by the improvement of ship locomotion, and secondly by the adoption of fixed ocean routes, the building of great ship canals, of which the Suez and the projected Panama canals are foremost examples, and by the improvements in harbors, wharves, dock appliances and accommodations at the termini of commerce. Of equal importance were the successive changes from wooden to iron hulls (about 1863), yielding larger and stronger ships with better and cheaper service; from iron to steel hulls, a fresh advantage in economy and capacity; the change from paddles to screws about 1850; from simple to compound engines about 1856, securing increased radius through decreased expenses for steam coal; the adoption of twin screws since 1889, and the development of the turbine steamer since 1895.

After the conclusion of the War of the Revolution, the United States merchant marine commenced its national existence. In May, 1789, James Madison, in the House of Representatives, stated that only 160,907 tons were foreign of the 437,641 tons (including repeated voyages) registered as entered in the ports of Massachusetts, New York, Pennsylvania, Maryland, Virginia, South Carolina, and Georgia. "This circumstance," continued Mr. Madison, "annexed to our capacity of increasing the quantity of our tonnage, gives us a favorable presage of our future independence." On 31 Dec. 1789, the merchant fleet of the United States amounted to 201,562 tons, of which 123,893 tons were registered for foreign trade, 68,607 tons for coasting trade, and the remainder for fisheries. By 1795 the tonnage of the United States merchant fleet had increased to 747,965 tons, and in 1820, notwithstanding the oppressive influence of the embargo acts, to 1,280,167 tons, 583,657 tons of which were in foreign trade, compared with a tonnage for the entire British empire of 2,648,593 tons. Three years later the American tonnage (including repeated voyages) entering the United States from foreign ports, amounted to 810,761 tons, compared with 119,487 foreign, of which 89,553 tons were British.

In 1850 the new ships built by the United States amounted to 272,218 tons, while those built by Great Britain amounted to only 133,695 tons. These relative positions changed in the decade preceding the Civil War: in 1860 our new tonnage was 214,798, that of Great Britain 301,535 tons. In 1855, the year of greatest construction, the United States built 2,027 vessels, of an aggregate tonnage of 583,450, of which 381 were full-rigged ships. But, by 1859, in a steady and rapid decline, without equal in our marine history, the product of the yards in four years fell to 875 vessels, of 156,602 tons, of which only 89 were full-rigged ships. In 1860 the new tonnage rose to 214,798, the steam fleet aggregating 867,937 tons, of which 97,296 tons were registered against a total steam tonnage of only 500,144 for the entire British empire. The decline of 1859 was not to be attributed to the substitution of steam for sail, this country, as the home of Robert Fulton, easily taking and maintaining the first rank in the early years of steam navigation. But the substitution of iron for wood — the staple shipbuilding material of this country at the period — completely altered the conditions of shipbuilding in our own and competing merchant marines, and gave the advantage to Great Britain with its cheap production of iron and lower cost of labor.

Previous to the decline, however, these disadvantages, largely offset by the superior skill and energy of the Americans in the building and management of ships, were also modified by the United States government extending its fostering care over the maritime interests of the nation in the same manner that other governments did to theirs. And, while our government pursued this course, our shipbuilders were enabled to produce ocean steamers superior in speed and fully equal in any other respect to those built elsewhere, while rapid progress was being made toward assuming a position in ocean steam navigation equal to that held in the days of sailing vessels. But when, owing to internal troubles, the government's fostering care was withdrawn, while foreign governments adhered to the policy of granting pecuniary aid to establish steamship lines with other countries, then did the United States maritime trade begin to decline, until it was comparatively driven from the ocean, but few American-built steamers crossed the Atlantic, and rarely was the American commercial flag seen in any port in Europe.

During the Civil War a large amount of American shipping was sold to foreigners, and the capital thus released was invested in the building of railroads under a system of enormous land grants — really subsidies, which the country was ready to vote for its immediate advantage, but denied to the shipping interests. The subsidies which should be granted to our builders to create a mercantile navy superior to any are, instead, paid to foreign shipowners in the shape of freight money, to an amount variously estimated at from $90,000,000 to $110,000,000 per annum, the greater part peacefully absorbed by Great Britain.

Confederate cruisers almost annihilated the Union merchant marine during the Civil War, capturing and burning most of the ships which had not been sold or hastily transferred to foreign flags. In 1861 the merchant marine was registered at 5,539,813 tons, and it was not until 41 years later, in 1902, that this figure was passed with a total of 5,797,902 tons. In 1903 it had reached 24,425 vessels of 6,087,345 tons, including canal boats and barges; there being registered 12,836 sailing vessels of 1,965,924 tons, exclusive of canal boats and barges, and 8,054 steam vessels of 3,418,088 tons, distributed among the geographical divisions of the Atlantic, Gulf of Mexico, the Pacific, Northern Lakes, Western rivers, Porto Rico, and Hawaii. In the coasting trade the tonnage of vessels registered was 5,141,037, or 282,323 tons more than 1902, and in the foreign trade and whale fisheries 888,776 tons, an increase of 15,541 tons over 1902.

Since 1898, throughout the world there has been a period of extraordinary activity in shipbuilding, in which the yards of the United States have shared, their average annual output being approximately 400,000 gross tons. This revival is due principally to the construction of the new navy. In anticipation of a steady run of work on government ships, new plants, equipped with the most modern appliances, were laid down, available, of course, for merchant ships also. During 1901 we built 1,491 vessels of 468,831 gross tonnage. Of 1,000 tons and upward there were launched 16 merchant vessels from 2,036 to 12,760 tons each, 95,105 in all; 5 steel ferry, river, and bay steamers, of 5,479 tons; with 7 square-rigged vessels aggregating 12,336 tons, 21 wooden schooners of 36,122 tons, and 4 rigged barges of 7,359 tons; total seagoing vessels of 1,000 tons and over, 53, aggregating 156,431 tons. It is interesting to note that that of the Great Lakes exceeded it, amounting to 41 vessels of 158,631 tons, while in 1904 there was launched for service on the Great Lakes the steamer "Wolvin," 560 feet long, then described as the largest fresh-water ship in the world, but surpassed in 1905 by four other mammoth fresh-water steamers, each of over 12,000 tons, 569 feet long, 56 feet beam, and 31 feet depth; these four vessels alone representing a total carrying capacity equal to the entire fleet of the Great Lakes 25 years ago. At the beginning of the fiscal year 1902-3 there were under construction or contracted for in our yards 25 steel steamships of 1,000 tons and upward. For the transatlantic trade there were 7 large vessels of 76,960 tons; including two 600-foot ships for the Atlantic Transport Line of 13,400 tons; the Finland of 12,760 tons, for the International Navigation Company; the Missouri and Maine of 9,800 tons each, for the Atlantic Transport Line; and for the same line two vessels of 8,900 tons each. For the transpacific trade there were two immense vessels of

AMERICAN SHIPPING COMPANIES, 1905.

Name of Owners.	No. of Vessels.	Gross Tonnage.	Routes.

20,000 tons each building at New London, Conn., for the Great Northern Steamship Company; same trade via Hawaii, the Siberia of 11,726 tons, for the Pacific Mail Company; Hawaii coasting trade, two of 8,600 tons each. For the Atlantic coasting trade there was a 9,000-ton vessel for the Standard Oil Company, a 6,250-ton for the New York & Texas Steamship Company, and a 5,252-ton ship for the Ocean Steamship Company; beside nine vessels from 1,000 to 4,577 tons.

Among notable modern passenger steamers, all steel, are the following:

The Kroonland, 12,760 tons, launched in 1901 (as was her sister the Finland); the largest ocean steamer ever built in America; constructed by the Cramps in Philadelphia for the International Navigation Company. Length over all, 580 feet; molded breadth, 60 feet; molded depth, 42 feet; displacement, 23,100 tons. Speed, 17 knots; engines, two triple-expansion, cylinders 32½, 54, and 89½ inches, 42-inch stroke; indicated horse-power, 10,200; boilers, 9 single-ended Scotch, 170 pounds pressure. Passenger capacity, 364 first class, 190 second class, 1,000 steerage.

The Korea, 11,276 tons, launched 1901; her sister, the Siberia, followed in 1902; they are largest and fastest steamers of any nationality running on the Pacific, the Korea the very fastest. They were built by the Newport News Shipbuilding Company for the Pacific Mail Steamship Company, and run between San Francisco, Japan, and China. Korea's average sea speed, 17.78 knots; on the trial trip she made the remarkable record of 18 to 19. Length over all, 572 feet 4 inches; molded depth, 41 feet 10 inches; displacement, 18,400 tons on 27-foot draft. Coal-bunker capacity, 2,600 tons; engines, twin quadruple-expansion, vertical inverted cylinders, 35, 50, 70, and 100 inches diameter, 66-inch stroke; boilers, 6 double and 2 single-ended Scotch, 200 pounds pressure. Passenger capacity, 210 first class, steerage 54 white and 1,144 Chinese.

The Sierra, built by the Cramps in 1900 for the Oceanic Steamship Company, one of three sister ships recently launched, to run from San Francisco to Honolulu (every 10 days), Samoa, Australia, and New Zealand (every three weeks), and Tahiti (every month). The Sierra is a very handsome twin-screw ship of 6,253 tons. Length, 400 feet; breadth, 50 feet 2 inches; molded depth to spar deck, 37 feet 2 inches. Engines, triple-expansion vertical, cylinders, 28, 46, and 75 inches diameter, 48-inch stroke; indicated horse-power, 8,000; speed, 17 knots; actual speed for the 7,200 miles from San Francisco to New Zealand, 15 knots. The three are constructed as auxiliary cruisers at need; with double bottom.

The Morro Castle, built by the Cramps in 1900 for the expanding West India trade; 6,004 tons gross; 8,280 displacement; length, 416 feet; breadth, 50 feet; molded depth, 36½ feet. She has a double bottom and seven steel bulkheads to the main deck. Engines, triple-expansion, 4-cylinder; cylinders, 32, 52, 60, and 60 inches diameter, 42-inch stroke; indicated horse-power, 8,000 at 170 pounds pressure. Sea speed, 17 knots. Passenger capacity, 104 first class, 60 intermediate, 44 second class. Crew, 117.

Other interesting facts are that the two largest cargo steamers ever built in America, the Shawmut and the Tremont, both of 9,606 tons, are plying regularly on their routes between Puget Sound, Japan, China, and Manila; that the Alaskan, of 8,716 tons, built at San Francisco, and now trading between Hawaii and the Atlantic coast, is the largest merchant steamer ever launched on the Pacific; while in river passenger boats a new vessel is being built in 1905 for service on the Hudson which surpasses in size, speed, and general equipment all hitherto constructed, the dimensions of the new boat being length, 400 feet, breadth, 82 feet, with accommodation for 5,000 passengers, and a speed of 23 miles an hour.

The year 1902 saw the consummation of a steamship combine, by which five of the largest transatlantic companies, the White Star, Dominion, Leyland, Atlantic Transport, and American Red Star, were merged into a single company with nearly 1,000,000 tons of shipping under its control. The combination was formed on strictly international lines, with a joint American and British control, the general manager of the line being an American with residence in this country. The organization was so arranged that the various companies included in the consolidation preserved their autonomy, and every consideration is shown their national and local surroundings. The combination was arranged to afford better transatlantic service at decreased cost, with more uniform rates, and a better distribution of traffic over the American and Canadian seaports. During the year 1902 both the largest vessel in the world and the fastest vessel at that time were launched, the Cedric, of 37,870 tons, about 1,000 tons larger than her sister ship the Celtic, and the Kaiser Wilhelm, with a sea speed of 24 knots. In size, although not in speed, these vessels were surpassed in 1905 by the steamship Amerika; length over all, 700 feet; breadth, 74 feet; depth, 53 feet; displacement, 42,000 tons; cargo capacity, 22,000 tons; built at Belfast, Ireland; while in 1906 will be launched the steamship Kaiserin Auguste Victoria, length over all, 705 feet; breadth, 77 feet; depth, 53.9 feet; built at Stettin, Germany. Innovations on these two steamers include elevator service between the five passenger decks, Turkish and electric baths, and modern à la carte restaurants.

American Microscopical Society, an association organized for the purpose of promoting microscopical studies by granting aid to members from invested funds, and by publication. Office of secretary, University of Nebraska, Lincoln, Neb.

American Mines and Mining. The adoption of new methods in mining operations has been justified by an improved product, a reduced productive cost, or an increased rate of production. The introduction of machine methods in mining marked a revolution in this field of activity, and the history of mining since that time has been largely the history of the development of mining machinery. There is no more significant evidence of this fact than is to be found to-day in the coal mines of this country. In this work the unusual conditions have been met by the development of special types of machines.

Coal is to-day the most powerful factor in

the industrial life of the world. Its production is the most important industry of the age, and it alone has made possible the marvelous development of the 19th century. In point of value, coal exceeds the total production of all other minerals. It will be conceded that an industry which in a few years has overshadowed all others is one to which the best thought must have been given and the highest skill applied. While this is true in every department which pertains to the handling of the product from the miner to the consumer, there has not been until quite recently a corresponding advance in the actual mining of the coal over the crude and laborious methods which obtained 50 years ago.

The rapid advancement of the American mining industry, aided by modern and inexpensive handling and splendid transportation facilities, is appreciated when it is noted that out of the world's annual production of 50,000,000 tons of pig iron, the United States alone furnishes about 20,000,000 tons, which if made into telegraph wire one-fifth of an inch thick, would extend from the earth to the sun. The yearly valuation of this product of pig or cast-iron is more than $250,000,000, while nearly $50,000,000 are annually paid in wages to about 85,000 men and boys employed in its production.

Legitimate mining, conducted as a business on business principles, is more certain of large profit than any mercantile or industrial occupation. A retrospect of mining in the United States will show that where skill and economy have figured in mining operations, the result has been to create riches for companies and individuals, in many instances beyond the dreams of avarice. The foundations of states and prosperous cities have been laid by mining men, due principally to the enormous profits that legitimate mines of this country have paid. Government statistics show that American mining properly conducted is one of the safest investments for capital, besides possessing the attraction, speculative to an extent, that every ten feet of shaft or tunnel made in a meritorious mine is liable to strike a bonanza of still richer ore. American mining has progressively gone forward until the present annual output in the United States exceeds $1,000,000,000 in value. The minerals, including natural gas and petroleum, contributing to this aggregate are in great variety, and may be classed as follows: Antimony, asbestos, asphaltum and bituminous rock, barytes, bauxite, borax, buhrstones and millstones, cement, clay, coal—anthracite and bituminous, copper, corundum and emery, crystalline quartz, feldspar, flint, fluorspar, fullers' earth, garnet, gold, graphite, grindstones and pulpstones, gypsum, infusorial earth, tripoli and pumice, iron ore, lead ore, lithographic stone, limestones and dolomites, lithium ore, manganese ore, marble, marl, mica—sheet and scrap, mineral pigments, monazite, oilstones, whetstones and scythestones, ozocerite, phosphate rock, platinum and iridium, precious stones, quicksilver, sandstones and quartzites, silica sand, siliceous crystalline rocks, silver, slate, sulphur and pyrite, talc and soapstone, tungsten, uranium and vanadium, zinc ore, chrome ore, magnesite, molybdenum, nickel and cobalt, and rutile.

When mining was in its infancy, the methods of drawing were primitive and cruel. First it was done by women and girls, who were used as beasts of burden. Then came the car running on wooden stringers, which in time gave place to iron rails, and finally dogs, ponies, mules and horses were substituted for hand labor in hauling. As the mines became larger in output and more extensive in distance, the need of better methods became imperative. The next improvement was the tail and endless rope, which through long years of service has proved both reliable and economical. Sometimes the power engines are at the surface, and often underground, operated by compressed air. Then there is the steam locomotive, the electric motor, the air locomotive, and the gasoline motor, the latter still experimental. Of these steam is used to a very limited extent, as the legal and mining conditions which admit of its operation are rarely found. Electric power is now successfully applied to such operations as hoisting, hauling, drilling and cutting, as well as lighting and the driving of pumps and ventilating apparatus. Electric wires may be run anywhere and under any conditions to be found in a mine; they are easily and quickly laid, occupy small space, and may be readily tapped whenever it is desired to operate machinery. In contrast with other means of power transmission, electricity does not require many isolated boiler and engine plants, with long, inflexible and costly lines of piping, nor does it involve complicated and troublesome mechanism which is costly to attend and maintain, but it makes possible a considerable saving through the utilization of water-power or the consolidation of independent steam-power plants. See MINES AND MINING.

American Newspapers. The history of the printing of newspapers in America properly begins on 25 Sept. 1690, for it was upon that date that Richard Pierce, of Boston, issued the first number of what was to have been a periodical publication. Strange as it may seem, however, this first American journalist was endowed with a sense of originality of which even the makers of the modern sensational newspaper might find reason to be proud, for, in his salutatory, he stated that as there were many false rumors being circulated in the town of Boston which were constantly doing a great deal of harm, he requested his readers to furnish him with a list of those persons who were starting such stories that he might advertise them in the succeeding issues of his paper. In other words, his plan was to print a regular weekly list of all the liars in town, a scheme which would certainly have sold many copies of the sheet had not the authorities put an end to the project by promptly suppressing the newspaper. This journal was to have borne the name of 'Public Occurrences, both Foreign and Domestic.'

As only one issue of this strange newspaper appeared, the historians of journalism have usually failed to mention it, but, instead, have given the credit for the publication of the first periodical to John Campbell, a Scotchman, and the postmaster at Boston, who issued the first number of 'The Boston News-Letter,' on 24 April

1704. It was printed on half a sheet of pot paper, with a small pica type, folio, and its entire contents consisted of several extracts from 'The London Flying Post,' in relation to the pretender; the queen's speech to Parliament regarding that subject; a few items of local news; four short paragraphs of marine intelligence from New York, Philadelphia, and New London, and a single advertisement — that of the proprietor. This was just 82 years after the appearance of the first English newspaper in London, and 99 years after the first newspaper in France. Germany had antedated all other countries, having made several short-lived attempts to establish periodical journals as early as the latter part of the 16th century.

For more than 15 years Campbell had the journalistic field entirely to himself, but, in the latter part of 1719, another paper, called 'The Gazette,' was started in Boston, and, in 1721, a third was established by James Franklin under the name of 'The New England Currant.' In the meantime there had appeared at Philadelphia the first newspaper published outside of New England. It was called 'The American Weekly Mercury,' and its first number was issued by Andrew Bradford, the son of William Bradford, 22 Dec. 1719. The first paper to be printed in New York was 'The New York Gazette,' established in Oct. 1725, but by 1740, the number of newspapers in the English colonies in America had increased to 11, three of which had been established in Pennsylvania — one being printed in German — one in New York, one in Virginia, one in South Carolina, and the remaining five in Boston.

In the beginning the American newspaper was a very small affair, being little more than an abstract of such papers as might chance to arrive from Europe on or about the date of publication. In fact, little change was made in them until after the time of the Revolution when the political agitators found it convenient to make use of them in presenting their appeals to the people. It was largely for this purpose that the first daily newspaper, 'The American Daily Advertiser,' was established in Philadelphia by Benjamin Franklin Bache, in 1774. During the time that the seat of government was at Philadelphia, it was this paper that was used by Jefferson to oppose the Federal section of Washington's administration as well as all measures which originated with Hamilton or his friends. In 1802, Zachariah Poulson became its proprietor, and the name which he gave to it, 'Poulson's Advertiser,' was retained until 1839, when it was consolidated with 'The North American.'

The second daily newspaper was 'The New York Daily Advertiser,' first issued on 1 Mar. 1785, by Francis Childs & Company. About a year later, 29 July 1786, the first newspaper appeared west of the Alleghany mountains. It was published at Pittsburg, Pa., and was called 'The Gazette.' During the early post-Revolutionary days, Alexander Hamilton's special organ was 'The United States Gazette,' a paper established in New York in 1789, by John Fenno, of Boston.

The territory comprised within the New England States had no permanent daily newspaper until 3 Mar. 1813, when the Boston 'Daily Advertiser' was started by William W. Clapp. Prior to that time two distinct attempts to establish such papers had been made. As early as 6 Oct. 1796, Alexander Martin, an Irishman, started 'The Polar Star,' which lived about six months. It was followed, 1 Jan. 1798, by Caleb P. Wayne's 'Federal Gazette,' which ceased publication in less than three months. Of the hundreds of papers started in New York between 1725 and 1827, when the first number of 'The Journal of Commerce' appeared, only two now survive, 'The Commercial Advertiser,' now better known as 'The Globe and Commercial Advertiser,' and 'The Evening Post.'

The history of the penny newspaper dates from 1830, the idea having been suggested by the 'Illustrated Penny Magazine,' first issued in London during that year. During the next few years, therefore, several similar attempts to introduce cheap papers were made in the United States, notably at Philadelphia and Boston. As these publications were always as small as they were cheap, however, they were but short-lived, and it was not until 1 Jan. 1833, when the price of 'The Morning Post,' was reduced to one cent by its publishers, Dr. Shepard, Horace Greeley, and Francis V. Story, that any pretentious effort was made to print a cheap newspaper. Although this experiment was not a success its failure was due to causes other than that of the price, so, when Benjamin H. Day established the New York 'Sun,' 3 September of the same year, he also fixed its price at one cent, and the day of the cheap press had come.

During the time which elapsed between the beginning of the 19th century and the year 1833 American journalism passed through two of the most important transition periods in its history. After having served its purpose as the mouthpiece of more or less patriotic agitators, it entered upon a period of party conflict, which, while fierce enough, was not always directed along judicious lines. Edited by adventurers, often brilliant men whose flashing wit attracted widespread attention to their utterances, this was the time in which the purpose of the American press could in no sense be depended upon. It was not until 1815, or a little later, that the newspapers of the country became pretty thoroughly emancipated from the control of these politicians. It was still more a political tract than anything else, however; it was narrow in its field and intolerant in its expressions, but

(A) Ayer's American Newspaper Annual.
*Tri-weekly.

still, at the same time, its utterances were delivered with freedom and courage. It was not until 1833 that the first real newspaper appeared. This was the New York 'Sun,' and the success of its policy of publishing the news instead of devoting its columns to the editor's personal and often eccentric opinions upon political matters was so immediate that it was soon followed by many rivals. Thus commenced the last and greatest period in the development of the American press.

STATISTICS OF AMERICAN NEWSPAPERS
(Taken from Ayer's American Newspaper Annual for 1905)

Totals	2,377	16,152	600	2,550	262	[illegible]	22,[illegible]12

No reliable statistics of newspapers were kept prior to 1810, at which time there were 366 publications of all classes in the United States. None of these publications appeared west of the Mississippi River, and only 25 of them were published daily. It is interesting to compare the number of newspapers published at that time with those issued in 1905. (The American Newspaper annual gives the preceding tables) The comparison is given in the tables at the top of the next column:

	Total	Daily	Semi-Weekly	Tri-Weekly	Weekly
1810	366	25	36	15	2[illegible]
1905	23,558	2,457	634	50	16,9[illegible]5

From reliable sources the following list of newspapers, which were started prior to or during the year 1800 and which are still in existence, was compiled:

MAINE.		
Portland	Advertiser	1785
NEW HAMPSHIRE.		
Keene	New Hampshire Sentinel	1799
	Cheshire Republican	1793

GEORGIA.		
Augusta	Chronicle	1785
OHIO.		
Cincinnati	Commercial Gazette	1793

In point of age the following are the ten oldest newspapers in the United States:

1. Annapolis, Md., Maryland Gazette 1745
2. Portsmouth, N. H., New Hampshire Gazette 1756
3. Newport, R. I., Mercury 1758
4. Hartford, Conn., Courant 1764
5. New Haven, Conn., Connecticut Herald and Journal 1766
6. Salem, Mass., Gazette and Mercury 1768
7. Worcester, Mass., Spy 1770

8. Baltimore, Md., America 1773
9. Windsor, Vt., Vermont Journal 1783
10. Alexandria, Va., Alexandria Gazette 1784

Prior to 1810 the circulation of the most widely read daily newspaper did not exceed 900 copies, while there were few publications, either weeklies or semi-weeklies, that could boast of a larger circulation than that of 600 copies. Supposing that there were 25 dailies in 1810, issuing 310 times a year; 36 semi-weeklies; seven tri-weeklies, and 290 weeklies, each with a circulation of about 600 copies, the aggregate circulation for the year would have been considerably less than 2,000,000 copies, while the value of the paper used could not have been in excess of $125,000. Compare those figures, therefore, with these from the United States census report for 1900, when the total sum invested in the newspaper and periodical publications of the country was stated to be $192,443,708; when there were 94,604 persons employed in this business, their total wages for the year amounting to $50,333,051, and when the total value of the newspapers and periodicals produced was fixed at $222,893,569. During the year 1900, no less than 956,335,921 pounds of paper were used by the newspapers in producing their aggregate circulation of 8,168,148,749. The cost of this paper was $22,197,060. During this year the amount received from advertising was $95,861,127, while the amount from subscriptions and sales was $79,928,483. Enormous as these figures may seem, however, they are now far too low, for the five years that have elapsed since the last census was taken has been a period of wonderful growth in every branch of the newspaper field. The following table is interesting as showing the steady development in number and circulation of the industry of daily paper making in America:

Year	Number of Daily Papers Published	Total Circulation Per Issue
1850	254	758,454
1860	387	1,478,435
1870	574	2,601,547
1880	971	3,566,395
1890	1,610	8,387,188
1900	2,235	15,102,156

To attempt to tell the story of the growth of the American newspaper without relating some particulars in regard to the wonderful feats which it has from time to time performed would be to give but a superficial view of the subject. Prior to the days of the telegraph the daily press had great difficulty in obtaining its information about current events in other parts of the country. To offset this disadvantage they adopted three methods of quick communication. One was by pony express; another was by carrier pigeons, and, when steam had been sufficiently developed to make fast travelling by rail or steamboat possible, special trains and boats were frequently chartered for special occasions. The New York 'Herald' and the New York 'Journal of Commerce' were the first papers to own swift sailing yachts which were used to obtain early information from incoming European vessels, while A. S. Abell, of the Baltimore 'Sun,' established his own overland express between New Orleans and Baltimore. This consisted of 60 blooded horses, housed at conveniently located relay stations, and the project was so successful that, during the Mexican War, he not only beat all the other newspapers in getting news, but he secured his information so far ahead of the government's own despatches, that he was able to advise the officials at Washington of important events, sometimes more than 30 hours before the reports of the happenings had been received at the War Office. Another instance of conspicuous enterprise was shown by Henry J. Raymond. While a reporter for the New York 'Tribune,' he was sent to Boston to report a notable speech by Daniel Webster. Returning by boat, he arranged to have the necessary composition frames and cases erected in his room, that, as fast as he could write, the sheets might be put into type, so that all were ready for publication the instant he reached the office.

In 1846, when the entire country was so greatly excited over the Oregon boundary dispute with Great Britain, several of the newspapers combined to send a swift pilot boat to England. There all the important news was obtained; the boat returned as quickly as it went, and the American people were provided with the information they craved many days before it could possibly have arrived if it had come by the ordinary channels, the slow-sailing vessels of that day.

As so much enterprise was shown by newspaper publishers at a time when the means of quick communication were few and costly, it was but natural that they should have hailed the steam railroad and the electric telegraph with delight. During the 10 years between 1840 and 1850, the period in which these inventions were first generally extended, the circulation of the American papers increased more than two-fold. In fact, they seized upon the telegraph with such avidity, that, to overcome the inconvenience and delay caused by the manner in which they were crowding one another, the press associations were formed, in 1850. By means of these associations the ordinary news which occurred in the populous parts of the country was sent, practically in duplicate, to all the papers subscribing to the service, and individual papers were compelled to rely upon special correspondents only for reports of such important events as they might desire to "cover" with more attention to detail. It was the same story in the latter sixties, when the cable had been laid, for it was this invention that made it possible for papers in the United States to obtain long reports of the progress of the Franco-Prussian War of 1870. Although the revision of the New Testament was completed at a time when cable rates were still very high, W. W. Story, of the Chicago 'Times,' ordered that 8,000 words of the new version should be cabled to his paper, and, when the complete work arrived at New York on the steamer, it was telegraphed to him in its entirety, 21 wires being used for that purpose.

Owing to the high rates at first charged for telegraph and cable messages the papers of those days did not get the almost unlimited news service which they receive to-day. Even as late as 1879 the night rate from California to Boston was 10 cents a word; between Chicago and Boston it was five cents a word, and between Washington and Boston, two cents a word. Since

that time the rates have been reduced fully 66 per cent, while the tolls paid by press associations is now about 14 cents per hundred words, irrespective of the number of papers to which the despatches are delivered. The original cable rate was $100 for 20 words, whether served to newspapers or to the general public, while the rate to newspapers is now but 10 cents a word, either for day or night service.

The result of the high tolls was shown in the compact despatches published by the newspapers of that day. For example, when the America won the international yacht race, 22 Aug. 1851, no report of the event was received by any American paper until 4 September, when the news came in the form of a despatch from Halifax. On this day the report in the New York 'Sun' contained about 500 words, the 'Tribune' used but 250 words about the contest, and the 'Evening Post' was content with 200 words. So, too, when Brooks assaulted Sumner, the Senator from Masachusetts, in 1854, the longest report sent to any Boston paper comprised less than half a column, and this was printed quite inconspicuously at the bottom of the page. In 1860, when Lincoln was nominated for the Presidency, at Chicago, one operator was able to send out all the press matter that was offered to him, while, at recent conventions, the hundred and more operators have had all they could do to handle the millions of words of descriptive matter filed with them by correspondents representing every newspaper of prominence in the country. When these facts are remembered, however, it does not seem so strange that the aggregate number of words of press matter that went over the Western Union wires in 1879 was but 28,000,000, whereas the total number of words contained in press specials handled by the same company in recent years has been no less than 10 times as great.

At the same time there was some excuse for the lack of interest displayed in news events. Those were the days of small and compact papers and even the best printing plants of that time would have been utterly unable to cope with such an avalanche of news as that which daily floods the modern newspaper office. At that day stereotyping had not been discovered, presses were slow, and hand-composition was the only method known to the trade. As papers were printed directly from the type, and as even the Hoe lightning steam-presses, patented in 1847, had a capacity which seems exceedingly slow when compared to that of presses to-day, newspapers with large circulation were compelled to go to press much earlier than their less popular rivals, a fact which placed them at great disadvantage in obtaining late news. The facilities for the distribution of papers were also few and inadequate, even for those days. Scarcely more than 40 years ago some of the most progressive journals in this country depended solely upon boys to carry their papers to their subscribers, while larger lots, the papers intended for dealers, were trundled through the streets on wheelbarrows. To-day all the newspapers have their own systems of fast delivery wagons, and the most progressive publishers charter "special" trains, not only for their Sunday editions, but frequently for other occasions during the year.

The first paper to begin the work of stereotyping its pages was the New York 'Tribune. This was in 1861. Four years later the Bullock perfecting press, made in Philadelphia, made it possible to print a paper from plates, both sides at the same time, at a rate of from 6,000 to 10,000 an hour. The R. Hoe & Company perfecting press appeared in 1871. This printed from 10,000 to 12,000 eight-page papers an hour, and it was quickly followed by the other Hoe inventions, the double press, the quadruple press, and, finally, the sextuple, with its working capacity of from 60,000 to 75,000 eight-page papers an hour, and with attachments capable of printing from 4 to 64 pages. The latest inventions are the color presses, made both by Hoe and by Scott, by means of which papers may be printed in several colors at once. As the result, every up-to-date newspaper office is now equipped with facilities for printing in almost every hue of the rainbow, although it is only within the last quarter of a century that publishers have attempted to use illustrations of any kind. During the late seventies an attempt was made to establish an illustrated daily, but the publication had but a brief existence. From that day illustrated journalism was practically unknown in America for many years. It was more than 20 years ago when the wood-cut was the only form of illustration adapted to newspaper uses, and as it required two or three days to make each wood-cut they were not available at short notice. Now, however, with all our facilities for almost instantaneous illustration it is no rare thing to find midnight happenings graphically pictured in the morning editions of the daily newspapers.

The invention of type-setting machines is another innovation that has an almost incalculable effect in the development of the modern newspaper. By the use of such a machine one operator is capable of performing as much work as three men could formerly do by the old method of hand composition. Some of these machines make a new cast of type each day, and all of them represent a marked increase of product at a great reduction in cost.

The growth of the Sunday newspaper dates from the Civil War, but it was many years after the conclusion of that struggle before the large Sunday editions began to make their appearance. In fact, it was less than 35 years ago that one of the leading papers in Boston increased the size of its Sunday issue from four to eight pages, and, strangely enough, the change met with all kinds of adverse criticism. During the next few days many of the subscribers to this journal called at the office to protest that the new paper was much too large, and this same criticism has continued as the great Sunday papers have steadily increased in size. In spite of the protests of these indignant critics, however, the fact remains that the American newspaper has simply kept pace with the development of the country. With greater facilities for news gathering, and with modern methods of distribution, the circulation of the prominent newspapers has increased to a degree that would once have been considered beyond all bounds of possibility. So, too, is this true in regard to advertising. Whereas, in 1810, the total amount of advertising printed in all the papers in the United States could scarcely have exceeded a few hundred thousand dollars, the in-

come from such sources to-day is now in excess of $100,000,000 per annum. To print all the news that the modern newspaper is required to print, to give space to all the features and special articles that the public has come to demand, and to find room for all these columns upon columns of advertisments, is certainly beyond the scope of any small, compact sheet. If it is true, as its friends claim, that the newspaper is one of the great sources of education in this country, upon what does this reputation rest? Certainly not upon its news alone, for the papers of every land describe the important happenings of the day. No, it is these special features, the articles descriptive of travel and of all the progress of the world in every field of human endeavor — in other words, the "magazine" articles that have now found wider circulation through the columns of the daily newspaper — that have made these organs what they now are, a great educational factor which has exerted more influence upon the development of the intelligence of the American people than it would be possible to estimate. Whatever the critics may think or say, therefore, one cannot deny the fact that newspapers are big to-day for the simple reason that they are required by the public, and those who are best acquainted with the journalistic situation find that every indication points to larger rather than to smaller papers. Great as this country is, it has by no means reached the end of its development, and, as it grows in population, and expands commercially, the demands upon the newspapers will necessitate a corresponding growth in this product of American industry.

Charles H. Taylor,
Editor 'Boston Globe.'

American Notes, a work by Charles Dickens, published in 1842 and embodying his impressions of the United States.

American Numismatic and Archæological Society, an association organized 1858, incorporated 1865. Its objects are the collection and preservation of coins and medals, the investigation of matters connected therewith, and the popularization of the science of numismatology; also the collection, examination, and elucidation of the antiquities of this and other countries. Membership about 300. See Numismatics.

American Oriental Society, an association organized in 1842 for the promotion of Oriental scholarship. All its publications are in the semi-annual journal of the society (cited as "Jaos"), which for 60 years has been an authority on Oriental subjects and in which appear monographs and special articles of all sorts relating to the Orient. The society has numbered among its presidents some of the most distinguished scholars of the country — Hadley, Woolsey, Whitney, etc., and from its inception has been a medium of communication between the East and the West. In age it outranks the German Oriental Society and all others except the Royal Asiatic Society of England. Membership, 350.

American Ornithologists Union, an association organized in 1883 for the advancement of its members in the science of ornithology. Membership, 825. It issues a quarterly magazine, 'The Auk.' See Ornithology.

American Party, the name of three separate political organizations in the United States.

1. The only one of great importance, usually styled "Know-Nothings." The genesis of this party lay deep in the nature of American settlement and history. The Constitution crystallized political parties definitely into Federalists and Anti-Federalists: the one upholding firm government on the general European model, with the local aristocracies in the ascendant; the other desiring the least possible government of any sort, and no upper-class ascendancy. Immigrants who had left Europe because of too free indulgence in freedom of speech, thought, and action, allied themselves with the Anti-Federalists, which led the incensed Federalists, on gaining power in 1795, to raise the term for naturalization from two to five years, and in 1798 to 14 years, besides passing the Alien and Sedition Laws (q.v.). The Republicans, coming into power with Jefferson in 1801, in 1802 repealed the obnoxious acts and restored the term to five, swelling their ranks for years with a relay of acrid foreign democrats. Six members of the Congress which declared the War of 1812 against Great Britain were members of the Society of United Irishmen; and the Federalist Hartford Convention of 1814 brought forward a provision against aliens holding office. Quiescent for many years, the movement revived (1835) in New York city, where a compact and clannish foreign body of immigrants, avid of office and openly allying themselves as foreigners against the natives, was accumulating; one procession bore a transparency lettered "Americans shan't rule us." The religious question was also then, as since, a formidable factor in the trouble. In 1843 the Democrats carried the city by a close vote, and distributed the majority of the offices to foreigners, with the result that in the November election for State Senator an "American Republican" candidate polled nearly a fourth of the vote, and the next spring a "Native American" candidate defeated the Democrat by 4,000, and the regular Whig party nearly vanished in the city. The excitement spread to New Jersey and Philadelphia; riots between natives and foreigners cost some lives and much property, including two Catholic churches. The Whigs voted with the Native party to secure its vote for Clay; but finding that it resulted in Native local officials and Democratic presidential majorities, drew off, and by 1847 the Native party had pretty much disappeared. Clay in 1844 had six Native American electoral votes, four from New York and two from Pennsylvania; and for some years the Middle States cast small votes for the party.

A new birth came to it about 1852. The Fugitive Slave Law of 1850 had largely dissolved and recombined both Whig and Democratic parties, and those of the former who wanted the *status quo* on slavery without public agitation cast about for a new issue to keep their organization together. The Native American issue was temptingly at hand, and indeed had never ceased to be a sore in the Whig mind. The tremendous flood of foreign immigration set going in part by the Irish famine of 1847, in part by the revolutionary movements of 1848–50 on the Continent, had kept a steady stream of reinforcements pouring into the Democratic party which almost swamped the

Whigs and made it quite impossible to win elections except by fusions that sacrificed all political principle or consistency; they felt it a genuine wrong to the native or long-resident classes, and there was nothing in the use to which the other party put their victories to make them feel otherwise. They now developed a secret oath-bound society whose real name was "Sons of '76, or Order of the Star-Spangled Banner"; but its name or precise object (of course they knew its general aim) was not revealed to members till the "lodges," which they instituted in imitation of the Masons, had raised them to the higher degrees. Hence their stock answer to questions concerning it was "I don't know," which became the popular motto of the order and gave them the nickname of "Know-Nothings." The evils it "viewed with alarm" were the increasing power of the Roman Catholic Church, the vast sudden flood of immigration which was taking the control of the United States out of the hands of its citizens, and the greed of foreigners for office which greatly multiplied the danger from their actual number. Its motto, or at least the essence of its principles, was "Americans must rule America,"— doubtless with a reminiscence of the foreign motto before mentioned; and the countersign at its lodges was an order said to have been issued by Washington at some unspecified occasion, "Put none but Americans on guard tonight." It acted in politics, not by putting up separate tickets, which would have kept tally on it and given the other parties a clear target and open victory, but by indorsing selected candidates of the others in secret convention of delegates from lodges, at which every member must vote or be expelled. This could not be known till election, and hence made havoc of all political calculations and left the workers beating the air. The Kansas-Nebraska Bill, which extinguished the Whig and created the present Republican party, and made the slavery issue one of life or death, drove into the Know-Nothing party a vast number of the moderate section not yet ready to oppose the South; it now took or was given the name of the American party, and came into the open field. In 1854 it carried Massachusetts and Delaware and polled over 120,000 votes in New York State. Thus far it had been almost wholly a Northern party; but in 1855 it made deep inroads in the South as well, where foreigners were few and the issue was locally innocuous. In that year it elected the governors and legislatures of New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, Kentucky, and California; the controller and legislature of Maryland and the land commissioner of Texas; and narrowly missed carrying the legislature of the latter, and those of Virginia, Georgia, Alabama, Mississippi, and Louisiana. But even at this time, when it was sweeping all before it, and the conservatives of both parties were crowding into it panic-stricken to avoid the real issues hurrying the country to the precipice, keen observers saw its hollow ephemerality: Horace Greeley of the New York *Tribune* said that "it contained about as much of the elements of permanence as an anti-cholera or an anti-potato-rot society." With 1856 it came into the national field, and for slavery tried to substitute terrific visions of a revival of the terrors of the Inquisition; denounced Archbishop Bedini, the papal nuncio, as an emissary of diabolic designs; and forced public discussions in which all the misdeeds of the mediæval Christian Church before and after 1520 were recounted. February 1856 a national nominating convention was held at Philadelphia; and its outcome, to the disgust of the majority, turned on slavery after all. A secret "grand council" held a session 19–21 February to draft a platform; and after three days of violent contention reported as part of it this curious "straddle," in later political slang: That all public offices should be given to native-born citizens, and the term before naturalization be 21 years; that "all laws" (that is, the Fugitive Slave Law) should be enforced till repealed or declared unconstitutional; that Pierce's administration be reprobated for repealing the Missouri Compromise; and that State councils be recommended to drop their "degrees" and substitute a pledge of honor from members,— that is, that it cease to be a secret terror to other parties and be one itself. But this meant death, as did its absurd attempt to gain Northern votes by opposing the Kansas-Nebraska Bill, and Southern votes by upholding the Fugitive Slave Law. In the open convention of 22 February, 50 Northern delegates offered a resolution that the secret grand council could not bind the convention by a platform; and on its rejection withdrew. The convention then nominated Millard Fillmore of New York for President, and Andrew Jackson Donelson of Tennessee for Vice-President; and the Whig national convention later adopted the nominations, but made no reference to the platform. In the spring of 1856 the party still increased its power, there being only local issues at stake; New Hampshire and Rhode Island elected "American" governors, making eight of the 32 States in their hands. But the presidential election showed what a phantom the party was: Fillmore gained the electoral vote of but one State, Maryland, with eight electors; the popular vote was 874,534 out of a total of 4,053,967; and in New Hampshire it sank from 32,119 for governor in spring to 422 in face of the real issue. It elected 15 or 20 Congressmen, carried Rhode Island and Maryland State elections in 1857, and in the Senate of December had five members. In the Congress of 1859 it had become a Border State party, with one Senator from Kentucky and one from Maryland, and 23 Congressmen,— three from Maryland, five from Kentucky, seven from Tennessee, one from Virginia, four from North Carolina, two from Georgia, and one from Louisiana. In the campaign of 1860 its members largely made up the Constitutional Union (Bell-Everett) party, which tried to avert the war. The party was by no means without its use: it brought forward many strong leaders who did good service in the real parties when the issues had shown themselves inevitable.

2. A party directly adverse to the first in being founded on opposition to secret societies: organized by the National Christian Association at the adjournment of its convention at Oberlin, Ohio, in 1872. Organization was completed and the name adopted at a convention in Syracuse, N. Y., in 1874. At Pittsburg, 9 June 1875, a platform was adopted demanding recognition of the Sabbath, introduction of the Bible into public schools, prohibition of the sale of liquors, withdrawal of the charters of secret

societies and prohibition of their oaths, international arbitration, restriction of land monopolies, resumption of specie payments, justice to the Indians, and direct popular vote for President and Vice-President. James B. Walker of Illinois was nominated for President. In 1880 it again made nominations; in 1884 S. C. Pomeroy was nominated, but withdrew in favor of John P. St. John, the Prohibition candidate.

3. A party organized at a convention in Philadelphia, 16–17 Sept. 1887. Its platform demanded a 14-years' residence for naturalization; exclusion of anarchists, socialists, and other dangerous characters; free schools; the building of a strong navy and coast fortifications, and internal improvements; prohibition of alien proprietorship; permanent separation of church and state; and enforcement of the Monroe Doctrine.

Connecticut Historical Society.

American Patriotic Societies. See PATRIOTIC SOCIETIES.

American Philological Association, a society inaugurated by William D. Whitney, of Yale, at Poughkeepsie, 1869 as an outgrowth of the Oriental Society, Classical Section. Its object is the same as that of the British Philological Society (q.v.); it publishes an annual volume of 'Transactions' and also 'Proceedings,' detailing its meetings and giving titles of papers presented. It has a membership of some 600.

American Philosophical Society, The, is the oldest scientific society in America. Benjamin Franklin, in his 'Autobiography,' states that in the year 1727 «I united the majority of well-informed persons of my acquaintance into a club which we called the Junto, the object of which was to improve our understandings.» As the population of the colonies grew, Franklin saw the need of a society of larger scope and usefulness than the Junto; therefore, in 1734, he issued a circular, entitled 'A proposal for promoting useful knowledge among the British plantations in America,' in which he urged «that one society be formed of virtuosi or ingenious men residing in the several colonies, to be called The American Philosophical Society, who are to maintain a constant correspondence. That Philadelphia, being the city nearest the centre of the colonies, communicating with all of them northward and southward by post, and with all the islands by sea, and having the advantage of a good, growing library, be the centre of the society.»

The proposition was favorably received, and in the following spring Dr. Franklin wrote to Gov. Cadwallader Colden, of New York, that the Society «is actually formed and has had several meetings to mutual satisfaction.» He gave a list of the members, and added that «there are a number of others in Virginia, Maryland, Carolina, and the New England colonies who we expect to join us as soon as they are acquainted that the Society has begun to form itself.»

In January 1769 this society united with another which had been subsequently formed in Philadelphia with a similar object, and entitled «The American Society held at Philadelphia for promoting Useful Knowledge,» and the consolidated societies took the fused name of «The American Philosophical Society held at Philadelphia for Promoting Useful Knowledge,» and elected Benjamin Franklin its first president, and he held this office by successive annual reëlections until his death in 1790.

The Society at once entered upon arrangements to carry out a notable scientific undertaking of great magnitude for those days, namely, to make observations of the expected transit of Venus in the following June — a rare phenomenon which had not occurred for 130 years and would not recur for 105 years. It erected three temporary observatories and appointed a committee, of which David Rittenhouse was the head, to have charge of the observations on the day of the eclipse. The weather in northern Europe was cloudy, but in the neighborhood of Philadelphia it was perfectly clear, and a high European authority has said that «the first approximately accurate results in the measurement of the spheres were given to the world, not by the schooled and salaried astronomers who watched from the magnificent royal observatories of Europe, but by unpaid amateurs and devotees to science in the youthful province of Pennsylvania.» The results of these observations were printed in the first volume of the Society's 'Transactions,' which was published in quarto form in 1771. The publication of the quarto 'Transactions' still continues, and in addition the Society publishes 'Proceedings' in octavo form.

Franklin was succeeded in the presidency by David Rittenhouse, the eminent astronomer, who held the office for five and a half years, until his death in 1796, and he in turn was succeeded by Thomas Jefferson, who held the office until 1815, including the eight years of his incumbency of the Presidency of the United States. «The tranquil pursuits of science,» he wrote, were his «supreme delight,» and the most exciting political duties could never withdraw him from them. Jefferson was succeeded in the presidency by Dr. Caspar Wistar, the eminent anatomist, and subsequent incumbents were Dr. Robert Patterson, Chief Justice Tilghman, Peters S. Du Ponceau, Robert M. Patterson, Dr. Nathaniel Chapman, Dr. Franklin Bache, Prof. Alexander Dallas Bache, Judge Kane, Dr. George B. Wood, Frederick Fraley, and Edgar F. Smith.

The membership of the Society since its foundation has included names distinguished in science on both continents. The number of members who may be elected in any one year is limited to 15 residents of the United States and 5 foreign residents. The election of members is held during the general meeting in April of each year. The ordinary meetings of the Society are held on the first and third Friday of each month, from October to May inclusive. The society possesses a library of over 40,000 volumes, which is specially rich in the files of the publications of the learned societies of the world, and is housed in a fire-proof building erected in Independence Square on land granted to it by the State of Pennsylvania in 1785.

I. MINIS HAYS,
Secretary American Philosophical Society.

American Political Issues, 1788-1852. By this term is here meant the issues which swayed the voters in the Presidential elections, and in the congressional elections of the Presidential years. These elections were the «round-up» or register

of the accumulated drift during the four years previous, and formed one of the influences deciding the drift during the next four. They fall into five periods: 1788–1800, 1804–12, 1816–20, 1824–40, 1844–52. In the first, the Federalists are in power; the controlling issues are those of strong *v.* weak government, and of deference to the educated classes *v.* the *vox populi.* In the second, the Federalists are the opposition, fling away the excuse for their existence, and after a casual sectional revival are extinguished. In the third, there are no issues and no party, properly speaking; the candidate is accepted by inertia from the old line of leaders, and the administration is able to grant the chief wishes of both the old sections. In the fourth, the former Federalist elements recombine under new names, with the basis of a strong spending and nationalizing government, replacing the dead issue of a strong executive one. In the fifth, the slavery question is the central issue.

1788.— The division over candidates has usually and naturally coincided with the division over policies; but in the first election, of 1788, it was not so. There was but one possible candidate, Washington; he represented all parties. He had seen the Revolution nearly aborted first, and the Confederation nearly wrecked afterward, by the weakness of the central government; this confirmed his natural bias as a "nationalizing" Federalist, anxious above all things for a government which could keep order, pay its debts, and secure respect from other nations. On the other hand, as a Southern farmer, he commanded the confidence of that section, which distrusted the Northern commercial interests; and as Washington, he was the idol of the masses everywhere. Furthermore, the very basis of the election had cut the ground from under the chief opposition party. The overshadowing issue, almost the only one, of the Confederation,— which had no president nor regular elections, but only scattering "by-elections" of congressmen,— was whether it should be replaced by a stronger government; the adoption of the Constitution had settled that, and the Anti-Federalists were shut down to voting for the personnel to administer a system they disliked and dreaded. Besides this, all their ablest sympathizers were Federalists for the time being, not from love of a strong government but experience of too weak a one; so that "Federalist" for election purposes meant not so much a party as almost every one in the country of capacity, experience, or business or intellectual standing.

1792.— Again Washington was the unanimous candidate. The same men substantially were sent to Congress; indeed, there were few Anti-Federalists to send who would not discredit and weaken the cause. But the Anti-Federalist voters had the less hesitation, because their natural leaders had now begun to split away and lay the foundations of the Democratic-Republican party. Jefferson was the first to take a stand against the Federalist policy, in the matter of the Bank; shortly reinforced by Madison and Edward Randolph.

1796.— Washington, who could have held the office for life, refused it further. There was now a contest over policies represented by candidates identified with them, and each representing a section as well: John Adams stood for the Northern commercial States, with most to lose from conflicting local impositions on commerce, or foreign depredations and restrictions which a weak government could not repel; Jefferson, the lifelong champion of the extreme democratic principle,— the least government, the cheapest, and the most unshowy, possible,— stood for the mass of farmers, largely in the South and West, who simply wished to be let alone and have no taxes, and thought commerce of no benefit or concern to them. The latter also formed a part of the rapidly growing mass who resented the Federalist claim that political office needed any superior ability or training, and were eager to pass it around in rotation. Quite as strong as either was the sympathy of the masses for the French Revolution, which the Federalists detested. The latter won, but only by grace of two Southern electors and in reality by a single vote; they lost save for these the entire South beyond Maryland, and all but one electoral vote of Pennsylvania as well. In a word, the party had represented a temporary national necessity which was ceasing to be imperative, and a minority business interest; and as the former vanished, it was shrinking to the basis of the latter.

1800.— For the personal feuds which rent the Federalists in twain, see ADAMS, JOHN, and HAMILTON, ALEXANDER; but the influence of these in defeating the party is always overrated. If Hamilton had loved Adams like a brother, and all Adams' cabinet had been loyal and united, the general result of the election would not have been different; unless we are to suppose that New York Federalists voted for Jefferson because their chiefs hated each other, or that the party's recent policy had gained it votes since 1796, which is notoriously the reverse of truth. It had not only angered the Democrats, but displeased many of its own moderates, by the Alien Law for deporting all foreigners politically disagreeable to it, and the Sedition Law to shut the mouths of its opponents (see ALIEN AND SEDITION LAWS); the Hamilton wing had tried to force through a war with France to strengthen its domestic policy; the growing popular sentiment now was to make the United States a political island, severed from all relations with the rest of the world which would cause us difficulties. The election was decided for Jefferson by the reversal of New York's 12 electoral votes: local feuds had something to do with it, Burr's political "bossship" much; but beyond all, the growth of the country was away from Federalism, and at best the party had not one electoral vote to lose without being displaced.

1804.— Had the relations of the parties remained the same as in 1800, there is still no reason to think there would have been any return to a Federalist administration. From 1789 to 1797 their programme had been not merely the best, but the only one as a whole possessing either utility, dignity, or even safety; yet the disintegrating forces were so strong, and the squalor of the Confederation so thoroughly forgotten, that the party barely escaped expulsion in the very prime of its usefulness. Even in the next four years, its errors were trivial compared with its services, especially in creating the navy; yet it was beaten — not very heavily, but with incidents proving that its lost sections would

not come back to it. But so far from the issues remaining the same, the Federalist representatives, with that egregious blindness to the sources of popular strength which is never seen except in "practical politicians," committed the amazing folly of attempting to tie their opponents' hands by borrowing all their discarded doctrines. The Democrats in power had at once become converts to a strong government and a liberal construction of the Constitution; the Federalists, instead of outdoing them and claiming support as the originators of the policy, adopted the strict-construction theories and the decentralizing policy of their opponents. The Democrats having appropriated the Federalists' strength, the latter revenged themselves by appropriating their enemies' weakness. This was especially glaring in the case of the Louisiana Purchase, an extreme Federalist measure, and by far the greatest title of Jefferson to the name of statesman: it is quite incredible that the Federalists should have opposed this, even as partisans, or as possessing the rudiments of political common-sense. Their astute policy received its fitting reward: in 1800 Jefferson had won by 73 to 65; in 1804 he received 162 to 14.

1808.— The Democrats, having had full power to put in force their cherished theories of insularity and independence of international ties, at once proceeded to make a *reductio ad absurdum* of them, and hang them like a sack of stones about their own necks. Jefferson was placed between the upper millstone of the English right of search and impressment, ending in the bloody outrage of the Leopard on the Chesapeake (q.v.), and the nether of his own resolve not to fight, the disbelief of all parties alike in our ability to fight a naval war with England, and the determination of the North, which possessed most of the fighting resources, not to use them against England. He solved the problem by the Embargo (q.v.), which saved the need of fighting by sacrificing the commerce he did not value, and the prosperity of a section he was quite resigned to see unprosperous. The moribund Federalist party gained a galvanic life from this, which for the time looked like a real one: in 1804 it had carried only Connecticut and Delaware and part of Maryland; in 1803 it carried all New England but Vermont (the one State which had no commerce to lose), three votes from North Carolina and Delaware, and the two Marylanders as before,— 47 in all.

1812.— The same causes which had operated during the previous four years had continued with ever growing efficacy during this four. The feeling against England among the Democrats, the feeling among the Federalists that England was fighting the world's battle against Napoleon and must not be crippled, ever grew in intensity; the misery and hate in New England with its hamstrung commerce kept pace with either; a generation of youths was growing up who never saw the Revolution,— the War of 1812 was officially determined by four Southerners between 26 and 29; and the conquest of Canada, instead of a naval war where it was universally believed our entire fleet would be at once seized and impressed into the British navy, had struck the war party as a happy resource. The political campaign of 1812 was made on the issue of war or a repeal of the non-intercourse act. Madison was given a second term on the express condition of his approving the war; he detested it as strongly as Jefferson, but as the majority had its teeth set, felt that he might as well head it as any one else. He secured it by 189 to 89; the Federalists by a fusion had carried, besides their old States, New York and New Jersey, and more of Maryland. A new era seemed coming for the Federalists; but it was an illusion. They had no party principles, and not even a party candidate except a borrowed one (George Clinton); and their entire basis of life now was on an issue by its nature temporary.

1816–20.— The close of the War of 1812 extinguished the old issues. The mostly inglorious land war had been forgotten in the blaze of New Orleans; we had proved that our navy not only could fight the queen of the world on equal terms, but would never again be wantonly defied; the people were full of satisfaction at coming out so well, and of anger at the Federalists, whose chief section had carried opposition to the point of discussing secession. Federalism was in many minds tainted with treason. Furthermore, the New England capital driven out of commerce by the embargo and the war had begun to re-embark in manufacturing, wished for a protective tariff, and could only have it from the governing element, which was hopelessly Democratic. Rhode Island, the first to establish mills, was the first of the southern tier to break away from its old allegiance. Massachusetts, Connecticut, and Delaware, by small majorities, clung to the ancient faith; but in 1816 the Democrats carried 16 States with 183 votes, including the rest of New England. The government had bid for these votes by a United States Bank and a light protective tariff; and in 1820, the "Era of Good Feeling," or rather of "No Issues," Monroe was elected unanimously save for the vote of one elector, disgusted with the business "rings" growing up around the administration.

1824.— The administration still further carried out Federalist ideas by a great system of internal improvements, and by strengthening the tariff. In a word, while nominally Democratic-Republican, its policy had become so Federalized as to have a stronger hold on its new allies than on its old constituents, and the issue in 1824 was whether that policy should be sustained or reversed. John Quincy Adams and Henry Clay represented the former, in different sections; Andrew Jackson the reaction to old-fashioned Democracy, with strict construction, economy, and no intermeddling with business development; William H. Crawford the regular Democratic "machine," with no ulterior purpose but office. Thus divided, no candidate had a majority. Jackson had the most; Adams was elected by the House of Representatives, still so far dominated by educated politics as to consider Jackson an ignorant and pestilent demagogue; he made Clay — who had the lowest vote of the four, but was the Southern leader most in accord with his policy, and the most of a statesman — secretary of state. This "Coalition" (q.v., No. 2) was denounced by the enraged Jacksonites as a corrupt bargain, and the House election as defeating the people's will; but there is no reason for assuming, as is currently done, that the anger gained Jackson any electoral votes.

1828.— The Democratic reaction had gained strength, and the Jackson enthusiasm swept all the factions into his fold, by virtue of the State

conventions which had now assumed the office of nominating. On that side the issue was much more Jackson than any definite party programme; but Jackson as representing the hatred of the masses, especially the Southern and Western masses, for the "money power," for all activities of government beyond keeping itself alive, for tariffs and government subventions, and for all claim of superiority in the educated class, and all political initiative except by spontaneous popular movements. In short, Jackson was the agent of a democratic revolution, which supported him with a swarm of new men, and approved his policy of turning out the trained officials neck and heels. Adams held his vote well: the stock reasons for his defeat — his ungraciousness, his refusal to employ patronage, his revival of charges against the New England Federalists — are absurd in face of the fact that he had but one vote less than in 1824, and of Jackson's enormous plurality. No candidate representing trained statesmanship, culture, and a liberal government policy, could have won this election.

1832.— The Democratic tide swept on overwhelmingly. Jackson's unprecedented use of the veto power to defeat internal-improvement schemes voted for by members of his own party, only bound the majority more tightly to him; his war against South Carolina for attempted nullification cost him her votes, but brought him reinforcements from the nationalist section; his hostility to the Bank of the United States was a prominent issue in the canvass, and was that of his constituents. Nothing better proves the senselessness of accounting for great political results by personal factions or squabbles, than the fact that Adams in 1824 and 1828 had more electoral votes than all Jackson's opponents together in 1832.

1836.— The issues of this year were the carrying on of Jackson's policy, though its great objects had been accomplished,— the deposits had been placed in State "pet banks" instead of the United States Bank,— and his dictation of his own successor. To oppose this dictation, one party sprung up with the ardent Jacksonian Hugh L. White as nominee, another as a Georgia State Rights faction,— though Jackson had championed the Georgia rights in the matter at issue (see CHEROKEE CASE); Jackson's influence, however, was powerful enough to nominate Van Buren as the "regular" candidate, and he was elected by a much reduced vote from Jackson's.

1840.— Few men have had a worse legacy than Van Buren received in the Presidency; and few have made a better use of it. Almost his entire term was occupied by the panic of 1837 and the three years of hard times which succeeded it; caused entirely by Jackson's "monkeying" with the currency of which he knew nothing. The State banks which replaced the United States Bank as depositaries, and were used as Democratic political machinery, instead of managing the funds with discretion as the old bank had done, issued masses of notes till a tremendous inflation of the currency had created a vast land speculation; then he suddenly withdrew recognition of the paper currency and brought the whole structure down with a crash. Van Buren was a politician, but he was a sound statesman and financier and an honorable public man: he would have no more meddling by the government with the banking business for which it was unfit, even to extricate his own administration from a scrape; and after three years' struggle he established the Sub-Treasury system, to the lasting benefit of the country. But with the customary popular perspicacity, he was made the scapegoat for calamities which he had not caused and whose renewal he had prevented. Furthermore, the Whigs outbid the Democrats in avowed submission to the "popular mandate," their candidate Harrison promising to disuse the veto; they outdid them in the "popular hero" line by turning a useful but not very brilliant Indian battle into a second Marathon, or rather repeating the name without discussing the details; capped their swarms of mythical anecdotes of Jackson's homespun habits and unpretentious heroism by an equal number about Harrison, models of his hypothetical "log cabin" and bibulous reproduction of his "hard cider" days; they made bargains and absorbed both the Southern free-lance opposition parties: and by all this and their campaign of "noise, numbers, and nonsense," carried all but three old States and four small new ones, 234 to 60 — a majority which suggests that possibly the noise and nonsense were not needed nor efficacious, and a quieter campaign of sensible argument might equally have won, with a real leader like Clay and no ruinous bargains.

1844.— Harrison had barely survived his inauguration; and the usual policy of "placating" the strongest part of the opposition by giving them the Vice-Presidency (Tyler) had produced its usual and deserved fruit of turning the administration over for the whole four years to the Nullification party, except so far as the Whigs tied its hands. This under Clay's leadership they did, consolidating the party by steady war on Tyler, and heartening themselves at last to do what they had not before and did but once again — put forth a platform. It was a very compact and well-expressed one, excellent from the Whig or present Republican standpoint; but it was displaced as an issue by far more exigent and pungent practical ones. The tariff of 1842, which was almost weeded of protectionist features by the joint efforts of Tyler and the Democrats, was made one of the arguments; but the decisive one was Texas. For years the great object of the Calhoun wing of the Democrats had been to annex Texas; partly to increase slave territory and balance Northern growth, partly with the immediate aim of disrupting the Whig party by forcing it to take a position which would drive away either the Northern or the Southern wing. Tyler, deprived of Whig support, again drew near to the Calhoun party to which he had formerly belonged; in 1844 Calhoun was made secretary of state; and with this administration backing, the Calhoun party obtained control of the Democratic national convention, committed it to Texas annexation, and gave the nomination to the Southerner Polk instead of the Northerner Van Buren. Clay was asked to declare himself on this point; he wrote an evasive letter which cost him the support of the political abolitionists (see LIBERTY PARTY), who nominated a ticket of their own with disastrous results to both. The three tickets were those of Polk, Clay, and Birney; the first on the issues of protection, distribution of land sales, cutting down Presidential power, and dodging all phases of the slavery question; the

second on the "*re*-occupation of Oregon and the *re*-annexation of Texas"; the third on immediate abolition of slavery. The last-named cast only 62,300 votes; but enough of those were in New York and Michigan to turn the former's 35 and the latter's 6 electoral votes from Clay to Polk, electing the latter, bringing in Texas, and bringing on the Mexican War.

1848.— The Mexican War had been the dominant issue for a couple of years before, and the Democrats had striven to make it destructive to the Whigs by forcing them into obnoxious declarations of principle; but the latter voted supplies for it, and evaded abstract pronouncements as to its righteousness. The Wilmot Proviso (q.v.) was a heavier blow, for the Southerners looked on it as a primary touchstone of sectional loyalty, which stood above party loyalty. The one salvation was a popular moderate candidate who could be accepted by the voters to whom the Democrats were simply impossible; and such a one was found in Gen. Zachary Taylor. A Louisiana slaveholder, no Southerner could suppose he would sign a bill endangering his own property; known to dislike the veto, he could be trusted by the North to obey the verdict of Congress if it passed the Proviso; a popular hero, he commanded the great unreflecting brute vote which supposes military and civil functions somehow related. He was elected by reason of a split in the New York Democracy, the country being about evenly divided; that he was elected at all, however, is remarkable proof of the terror of the conservative masses at having the slavery firebrand thrown into politics. It was this vote which elected the Whigs Clay and Taylor (the former really elected so far as the Democratic competitor went), and the Democrats Pierce and Buchanan, each in the hope of suppressing the question altogether.

1852.— Taylor died in 16 months, and the Vice-President Fillmore completed the term; but all through the four years each of the two parties of unlimited slavery extension and slavery restriction was drawing its ranks together, and forming into the parties soon to contest the final mastery. In place of Whig and Democrat, it was increasingly North and South. Unfortunately, the South was willing to fight and the North as yet was not; and the so-called Compromise of 1850, like most compromises, was practically all on one side, the Northern Whigs letting the measure go by default. They did not like it, but the South insisted, and they had much more confidence in placating their own constituents for adhering to it than the South for not doing so; once passed, therefore, they proclaimed it a sacred and irrepealable decision, as being a "compromise," and the Fugitive Slave part as being a sacred obligation to uphold. As always, the "reopening of agitation" was executed by the Southern wing: before the Presidential nominations were made, they had determined to force the Whigs to an absolute declaration of party policy, a touchstone of legitimate membership. First at the Whig caucus of 20 April, then at the Baltimore national convention of 16 June, they insisted on the party recognizing the Compromise as a finality: in the platform, the last article, of great length and minuteness, made the Fugitive Slave Law, by name, a part of the organic constitution of the party. This was death, and the Southern Whigs must have so intended it. Gen. Scott, as a military hero, was made the candidate. The Southern Whigs, instead of voting for him on account of the Fugitive Slave plank, largely voted against him because the anti-slavery men in the convention, for no assignable reason, had voted for him, and he was said to be partial to Seward; the Northern Whigs largely voted against the platform: and the Whigs carried only four States, Massachusetts, Vermont, Kentucky, and Tennessee, and less than a third of the next Congress even nominally, a third even of that being Southerners who soon became Democrats. The Whig party was no more: "died of an attempt to swallow the Fugitive Slave Law" was the epitaph proposed for it.

FORREST MORGAN.
Connecticut Historical Society.

American Political Issues, 1856-1900. My review will begin with the year 1856 — the year in which I cast my first vote, also one in which James Buchanan was chosen President. But it must be premised that each election does not represent a debate; not infrequently it is merely a stage in a debate. It was so in 1856; it has been so several times since. Indeed, since 1840 — the famous "Log Cabin and Hard Cider" campaign of "Coon-Skin Caps," and "Tippecanoe and Tyler too," probably the most humorous, not to say grotesque, episode in our whole national history, that in which the plane of discussion reached its lowest recorded level — since 1840 there have been only six real debates, the average period of a debate being therefore 10 years. These debates were (1) that over slavery, from 1844 to 1864; (2) that over reconstruction, from 1868 to 1872; (3) legal tenders, or "fiat money," and resumption of specie payments were the issues in 1876 and 1880; (4) the issue of 1888 and 1892 was over protection and free trade; (5) the debate over bimetallism and the demonetization of silver occurred in 1896; and, finally (6), imperialism, as it is called, came to the front in 1900. Since 1856, therefore, the field of discussion has been wide and diversified, presenting several issues of great moment. Of necessity also the debates have assumed many and diverse aspects, ethnical, ethnological, legal, military, economical, financial, historical. The last is that which interests us.

Slavery Issue.— The first of the debates I have enumerated, that involving the slavery issue, is now far removed. We can pass on it historically; for the young man who threw his maiden vote in 1860, when it came to its close, is now nearing his grand climacteric. Of all the debates in our national history that was the longest, the most elevated, the most momentous, and the best sustained. It looms up in memory; it projects itself from history. As a whole, it was immensely creditable to the people, the community at large, for whose instruction it was conducted. It has left a literature of its own — economical, legal, moral, political, imaginative. So far as the historical aspect of that great debate is concerned, two things are to be specially noted. In the first place the moral and economical aspects predominated; and, in the second place, what may be called the historical element as an influencing factor was then in its infancy. The slavery debate was so long and intense that all the forces then existing were drawn into it. The pulpit, for instance, participated

actively. The physiologist was much concerned over ethnological problems, trying to decide whether the African was a human being or an animal; and, if the former, was he of the family of Cain. Thus all contributed to the discussion; and yet I am unable to point out any distinctly historical contribution of a high order; though on both sides the issue was discussed historically with intelligence and research. Especially was this the case in the arguments made before the courts and in the Scriptural dissertations; while on the political side the speeches of Seward and Sumner, of Jefferson Davis and A. H. Stevens, leave little to be desired. The climax was perhaps reached in the memorable joint debate between Lincoln and Douglas, of which it is not too much to say the country was the auditory.

Beginning in its closing stage, in December 1853, when the measure repealing the Missouri Compromise of 1820 was introduced into the Senate of the United States, and closing in December 1860, with the passage of its ordinance of secession by South Carolina, this debate was continuous for seven years, covering two Presidential elections, those of 1856 and 1860. Of the great slavery debate it may then in fine be said that, while the study of history and the lessons to be deduced from history contributed not much to it, it made history, and on history has left a permanent mark. Of the canvass of 1864, from our point of view little need be said. There was in it no great field for the historical investigator, the issue then presented to the people being of a character altogether exceptional. The result depended less on argument than on the outcome of operations in the field. Nor was it greatly otherwise in the canvass of 1868. The country was then stirred to its very depths over the questions growing out of the war. The shattered Union was to be reconstructed; the slave system was to be eradicated. These were great political problems; problems as pressing as they were momentous. For their proper solution it was above all else necessary that they should be approached in a calm scholarly spirit, observant of the teachings of history. Never was there a greater occasion; rarely has one been so completely lost. The assassination of Lincoln silenced reason; and to reason and to reason only does history make its appeal. The unfortunate personality of Andrew Johnson now intruded itself; and, almost at once, what should have been a calm debate degenerated into a furious wrangle. Looking back over the canvass of 1868, and excepting General Grant's singularly felicitous closing of his brief letter of acceptance —"Let us have peace"— I think it would be difficult for anyone to recall a single utterance which produced any lasting impression.

Reconstruction.— The debate over reconstruction, begun in 1865, did not wear itself out till 1876. In no respect will it bear comparison with the debate over slavery which preceded it. Sufficiently momentous, it was less sustained, less thorough, far less judicial. Toward its close, moreover, as the country wearied, it was gravely complicated by a new issue; for, in 1867, began that currency discussion destined to last in its various phases through the lifetime of a generation. It thereafter entered in greater or less degree into no less than nine consecutive Presidential elections, two of which, those of 1876 and 1896, actually turned on it.

Currency Issue.— The currency debate presented three distinct phases: First, the proposition, broached in 1867, known as the greenback theory, under which the interest-bearing bonds of the United States, issued during the Civil War, were to be paid at maturity in United States legal tender notes, bearing no interest at all. This somewhat amazing proposition was speedily disposed of; for early in 1869 an act was passed declaring the bonds payable "in coin." But, as was sure to be the case, the so-called "fiat money" delusion had obtained a firm lodgment in the minds of a large part of the community, and to drive it out was the work of time. It assumed too, all sorts of aspects. Dispelled in one form, it appeared in another.

It is difficult to say what the dividing issue of 1876 really was. The country was then slowly recovering from the business prostration which followed the collapse of 1873. The living debate was over material questions, the cause of the prolonged business depression and the remedy for it. The favorite specific was at first a recourse to paper money. The government printing-press was to be set in motion in place of the mint; and even hard-money Democrats of the Jacksonian school united with radical Republicans of the reconstruction period in guaranteeing a resultant prosperity. Again the teachings of history were ignored. What, it was contemptuously exclaimed in the Senate, do we care for "abroad!" From this calamity the country had been saved by the veto of President Grant in 1874; and the following year an act was passed looking to the resumption of specie payments on 1 Jan. 1879. Seventeen years of suspension were then to close. Over this measure the parties nominally joined issue in 1876. The Republicans, nominating Governor Hayes of Ohio, demanded the fulfilment of the promise; the Democrats, nominating Governor Tilden of New York, insisted on the repeal of the law. Yet it was well understood that the candidate of the Democracy favored the policy of which the law in debate was the concrete expression. The contest was thus in reality one between the "ins" and the "outs."

But not the less for that, in the canvass of 1876 a field of great political usefulness was opened up to the historical investigator; a field which, I submit, he failed adequately to develop. A public duty was left unperformed. From time immemorial to tamper with the established measures of value has been the constant practice of men of restless and unstable mind, honest or dishonest, whether rulers or aspirants to rule.

The Tariff Issue.— The administration of President Hayes was curiously epochal. During it the so-called "carpet-bag governments" disappeared from the Southern States; the country resumed payments in specie; and on 28 Feb. 1878, Congress passed over the veto of the President an act renewing the coinage of silver dollars, the stoppage of which, five years before, constituted what was destined thereafter to be referred to as "the crime of 1873." This issue, however, matured slowly. Public men, having recourse to palliatives, temporized with it; and through four Presidential elections it lay dormant, except in so far as parties pledged themselves to action calculated, in the well-nigh

idotic formula of politicians, to "do something for silver." The canvasses of 1880 and 1884 are therefore devoid of historical interest. The first turned largely on the tariff; and yet, curiously enough, the single utterance in that debate which has left a mark on the public memory was the wonderful dictum of Gen. Hancock, the candidate of the defeated opposition, that the tariff was a local issue, which a number of years before had excited a good deal of interest in his native State of Pennsylvania. Nor is the recollection of the debate of 1884 much more inspiring. It was a lively contest enough, under Grover Cleveland and James G. Blaine as opposing candidates, a struggle between the "outs" to get in and the "ins" not to go out. But a single formula connected with it comes echoing down the corridors of time, the alliterative "Rum, Romanism, and Rebellion" of the unfortunate Burchard.

That of 1888, presenting at last an issue, rose to the dignity of debate. In his annual message of the previous December the President, in disregard of all precedent, had confined his attention not only to the tariff, but to a single feature in the tariff, the duty on wool. In so doing he had, as the well understood candidate of his party for re-election, flung down the gauntlet, for only three years before the Republicans, in the Presidential platform, had laid particular emphasis on "the importance of sheep industry" and "the danger threatening its future prosperity." They had thus pledged themselves to "do something" for wool, as well as for silver, and the President now struck at wool as "the tariff-arch keystone." But, while in this debate the economist came to the front, there was no pronounced call, and, indeed, small opportunity for the historian.

Three Great Issues.— Returning to the review of our national debates, we find that in 1892 the shadow of coming events was plainly perceptible. The tariff issue had now lost its old significance; for the infant industries had developed into trade- and legislation-compelling trusts. These were suggestive of new and, as yet, inchoate problems; but to them the constituency was not prepared intelligently to address itself. Populism was rife, with its crude and restless theories; a crisis in the history of the precious metals was clearly impending with the outcome in doubt; indiscriminate and unprecedented pension-giving had reduced an overflowing exchequer to the verge of bankruptcy. The debate of 1892 accordingly dropped back to the politician's level, that of 1876, 1880, and 1884.

Of quite another character were the two canvasses of 1896 and 1900. Still fresh in memory, the echoes of these have indeed not yet ceased to reverberate; and I assert without hesitation that not since 1856 and 1860 has this people passed through two such wholesome and educational experiences. In 1896 and in 1900, as in the debates of 40 years previous, there was a place, and a larger place, for the student, whether investigator or philosopher. Great problems, problems of law, of economics and ethics, problems involving peace and war, and the course of development in the oldest as in the newest civilizations, had to be discussed on the way to a solution. That the prolonged debate running through those eight years was at all equal to the occasion I do not think can be claimed. Even his most ardent admirers will hardly suggest that Mr. Bryan in 1896 and 1900 rose to the level reached by Lincoln 40 years before, nor do the utterances of Mr. Roosevelt, Mr. Depew, or Mr. Hanna bear well a comparison with those of Seward, Trumbull, and Sumner. Indeed, in the whole wordy canvass of 1896 I now recall but two instances of the professor or philosopher distinctly taking the floor; but both of those were memorable. They imparted an elevation of tone to discussion, immediately and distinctly perceptible, in the press and on the platform. I refer to the single utterance of Carl Schurz before a small audience at Chicago on 5 Sept. 1896 and to the subsequent publications of President Andrew D. White, in which, from his library at Ithaca, he drew freely on the stores of historical experience in crushing refutation of demagogical campaign sophistry.

What were the issues of the last Presidential canvass? On what questions did its debate turn? Three in number, they were, I think, singularly inviting to those historically minded. To the reflecting man the matter first in importance was what is known as "imperialism," the problem forced on our consideration by the outcome of the war with Spain. Next I should place the questions of public policy involved in the rapid agglomerations of capital, popularly denominated trusts. Finally, the silver issue still lingered at the front, a legacy from the canvass of four years previous. The debate of 1900 is a thing of the past. Each of those issues can now be discussed, as it might well then have been discussed, in the pure historical spirit. Let us take them up in their inverse order.

Silver and Trusts.— Shortly after 1870 the policy of demonetizing silver was entered on; and in 1873 the United States gave its adhesion to that policy. Thereafter, in the great system of international exchanges, silver ceased to be counted a part of that specie reserve on which drafts were made. Thenceforth the drain, as among the financial centres, was to be on gold alone. In the whole history of man no precedent for such a step was to be found. So far as the United States was concerned the basis on which its complex and delicate financial fabric rested was weakened by one-half; and the cheaper and more accessible metal, that to which the debtor would naturally have recourse in discharge of his obligations, was made unavailable. It could further be demonstrated that without a complete readjustment of our currencies and values the world's accumulated stock and annual production of gold, could not, as a monetary basis, be made to suffice for its needs. A continually recurring contest for gold among the greatest financial centres was inevitable. "A change which," in the language of Lecky, "beyond all others affects most deeply and universally the material well-being of man had been unwittingly challenged." The only question was, Would the unexpected occur? Then, if it did occur, what might be anticipated? Such was the silver issue, as it presented itself in 1896. On the facts, the weight of argument was clearly with the advocates of silver.

Four years later, in 1900, the unexpected had occurred. As then resumed, the debate was replete with interest. The lessons of 1892 and 1896 had a direct bearing on the present, and in the light shed by them the outcome could be

forecast almost with certainty; but it was a world question. Japan, China, Hindustan, entered into the problem, in which also both Americas were factors. It was a theme to inspire Burke, stretching back, as it did, to the Middle Ages, and involving the whole circling globe. Rarely has any subject called for more intelligent and comprehensive investigation; rarely has one been more confused and befogged by a denser misinformation. The discoverer and scientist, moving hand in hand, had during the remission of the debate, been getting in their work, and under the touch of their silent influence the world's gold production rose by leaps and bounds. Less than 10,000,000 ounces in 1896, in 1899 it had nearly touched 15,000,000; and in money value it alone then exceeded the combined value of the gold and silver production of the period.

So much for the silver question and its possible treatment. In the discussion of 1900 the last word in the debate of 1896 remained to be uttered. A page in history, both memorable and instructive, was to be turned. Next, trusts — those vast aggregations of capital in the hands of private combinations, constituting practical monopolies of whole branches of industry, and of commodities necessary to man. Was the world to be subject to taxation at the will of a moneyed syndicate? The debate over this issue, if debate it may be called, is still very recent. In it the lessons of history were effectually ignored; and yet, if applied, they would have been sufficiently suggestive. The historian was as conspicuous for his absence as the demagogue was in evidence.

The curious feature in the present discussion, that which in the mind of the student of things as opposed to words imparts a special interest to it, is that, while the trust of vast aggregation of capital and machinery of production in the hands of individuals intended to control competition is in fact the modern form of monopoly, is is in its methods and results the direct opposite of the old time monopoly; for, whereas the purpose and practice of that was to extort from all purchasers an artificial price for an inferior article through the suppression of competitors, the first law of its existence for the modern trust is, through economies and magnitude of production, to supply to all buyers a better article at a price so low that other producers are driven from the market. The ground of popular complaint against them is not that they exact an inordinate profit on what they sell, but that they sell so low that the small manufacturer or merchant is deprived of his trade. This distinction with a difference explains at once the wholly futile character of the politician's outcry against trusts. It is easy, for instance, to denounce from the platform the magnates of the sugar trust to a sympathizing audience; and yet not one human being in that audience, his sympathies to the contrary notwithstanding, will the next morning pay a fraction of a cent more per pound for his sugar, that by so doing he may help to keep alive some struggling manufacturer who advertises that his product does not bear the trust stamp.

As to the outcome of conflicts of this character history tells but one story. They can have but one result, a readjustment of industries. A single familiar illustration will suffice. Any one who chooses to turn back to it can read the story of the long conflict between the loom and the spindle. Formerly, and not so very far back, the distaff and spinning-wheel were to be seen in every house; homespun was the common wear. To-day the average man or woman has never seen a distaff, or heard the hum of a spinning-wheel. Ceasing long since to be a commodity, homespun would be sought for in vain. Yet the struggle between the loom of the manufacturing trust and the old dame's spinning-wheel was, literally, for the latter a fight to the death. The operator's time was worth absolutely nothing except at the wheel; she must needs work for any wage; on it depended her bread. A vast domestic, industrial readjustment was involved; one implying untold human suffering. The result was, however, never for an instant in doubt. The trust of that day was left in undisputed control of the field; and it always must, and always will be, just so long as it supplies purchasers with a better article at a lower price than they had to pay before. The process does not vary; the only difference is that each succeeding readjustment is on a larger scale and more far-reaching in its effects.

Such, stripped of its verbiage and appeals to sympathy, is the trust proposition. But the popular apprehension always has been, as it now is, that this supply of the better article at a lower price will continue only till the producer, the monopolist, has secured a complete mastery of the situation. Capital, it is argued, is selfish and greedy, corporations are proverbially soulless and insatiable; and, as soon as competition is eliminated, nature will assert itself. Prices will then be raised so as to assure inordinate gains; and when, in consequence of such profits, fresh competitors enter the field, they will either be crushed out of existence by a temporary reduction in price, or absorbed in the trust. All this has a plausible sound; and of it as a theory of practical outcome the politician can be relied on to make the most. But on this head what has the historical investigator to say? His will be the last word in that debate also; his verdict will be final. The lessons bearing on this contention to be drawn from the record cover a wide field of both time and space; they also silence discussion. They tend indisputably to show that the dangers depicted are imaginary. The subject must, of course, be approached in an unprejudiced spirit and studied in a large, comprehensive way. Permanent tendencies are to be dealt with; and exceptional cases must be instanced, classified, and allowed for. Attempts, more or less successful, at extortion in a confidence of mastery, can unquestionably be pointed out; but in the history of economical development it is no less unquestionable that, on the large scale and in the long run, every new concentration has been followed by a permanent reduction of price in the commodity affected thereby. The world's needs are continually supplied at a lower cost to the world. Again, the larger the concentration the cheaper the product; till now a new truth of the market place has become established and obtained general acceptance, a truth of the most far-reaching consequence, the truth that the largest returns are found in quick sales at small profits.

Does history furnish any instance of a financial, an industrial, or a commercial enterprise — a bank, a factory, or an importing company — ever having been powerful enough long to regu-

late the price of any commodity regardless of competition except when acting in harmony with and supported by governmental power? Is not the monopolist practically impotent unless he has the constable at his call? To answer this question absolutely would be to deduce a law of the first importance from the general experience of mankind. So doing would call for a far more careful examination than is now in my power to make, were it even within the scope of my ability; but if my supposition prove correct the corollary to be drawn therefrom is to us as a body politic and at just this juncture one of the first and most far-reaching import. In such case the modern American trust, also, so far as it enjoys any power as a monopoly, or admits of abuse as such, must depend for that power and the opportunity of abuse solely on governmental support and cooperation. Its citadel is then the custom-house. The moment the United States revenue officer withdrew his support the American monopolist would cease to monopolize, except in so far as he could defy competition by always supplying a better article at a price lower than any other producer in the whole world.

The Issue of Imperialism.— It remains to pass on to the third and last of the matters in debate during 1900, that known as imperialism. This was the really great issue before the American people then; and it is the really great issue before them now. That issue, moreover, I with confidence submit, can be intelligently considered only from the historical standpoint. Indeed, unless approached through the avenues of human experience, it is not even at once apparent how the question, as it now confronts us, arose and injected itself into our political action; and accordingly, it is in some quarters even currently assumed that it is there only fortuitously, a feature in the great chapter of accidents, a passing incident, which may well disappear as mysteriously and as suddenly as it came. Studied historically, I do not think this view of the situation will bear examination. On the contrary, I fancy even the most superficial investigator, if actuated in his inquiry by the true historical spirit, would soon reach the conclusion that the issue so recently forced on us had been long in preparation, was logical and inevitable, and for our good or our evil must be decided, rightly or wrongly, on a large view of great and complex conditions.

Leslie Stephen, in one of his essays, truly enough says: "The Catholic and the Protestant, the Conservative and the Radical, the Individualist and the Socialist, have equal facility in proving their own doctrines with arguments which habitually begin, 'All history shows.' Printers should be instructed always to strike out that phrase as an erratum, and to substitute 'I choose to take for granted.'" And elsewhere the same writer lays it down as a general proposition that: "Arguments beginning 'All history shows' are always sophistical." What is by some known as the doctrine of manifest destiny is, I take it, identical with what others, more piously minded, refer to as the will, or call, of God. The Mohammedans say: "God clearly calls us" to this or that work; and with a conscience perfectly clear proceed to rob, slay, and oppress. In like manner the political buccaneer and land pirate proclaims that the possession of his neighbor's territory is rightfully his by manifest destiny. The philosophical politician next drugs the conscience of his fellowmen by declaring solemnly that "all history shows" that might is right; and with time, the court of last appeal, it must be admitted possession is 9 points in the law's 10. It cannot be denied, also, that quite as many crimes have been perpetrated in the name of God and of manifest destiny as in that of liberty. That, at least, "all history shows." But, all the same, just as liberty is notwithstanding a good and desirable thing, so God does live and will, and there is something in manifest destiny. As applied to the development of the races inhabiting the earth it is, I take it, merely an unscientific form of speech; the word now in vogue is evolution, the phrase "survival of the fittest." When all is said and done that unreasoning instinct of a people which carries it forward, in spite of and over theories to its manifest destiny, amid the despairing outcries and long-drawn protestations of theorists and ethical philosophers, is a very considerable factor in making history; and consequently one to be reckoned with.

In plain words, then, and Mr. Stephen to the contrary notwithstanding, "all history shows" that every great, aggressive, and masterful race tends at times irresistibly toward the practical assertion of its supremacy, usually at the cost of those not so well adapted to existing conditions. In his great work Mommsen formulates the law with a brutal directness distinctly Germanic: "By virtue of the law that a people which has grown into a state absorbs its neighbors who are in political nonage, and a civilized people absorbs its neighbors who are in intellectual nonage — by virtue of this law, which is as universally valid and as much a law of nature as the law of gravity — the Italian nation (the only one in antiquity which was able to combine a superior political development and a superior civilization, though it presented the latter only in an imperfect and external manner) was entitled to reduce to subjection the Greek States of the East which were ripe for destruction, and to dispossess the peoples of lower grades of culture in the West — Libyans, Iberians, Celts, Germans — by means of its settlers; just as England with equal right has in Asia reduced to subjection a civilization of rival standing, but politically impotent, and in America and Australia has marked and ennobled and still continues to mark and ennoble extensive barbarian countries with the impress of its nationality."

The following quotation I must commend to the thoughtful consideration of those classified in the political nomenclature of the day as Anti-Imperialists. A most conscientious and high-minded class, possessed with the full courage of their convictions, the efforts of the Anti-Imperialists will not fail, we and they may rest assured, to make themselves felt. They enter into the grand result. Nevertheless, for them there is food for thought, perhaps for consolation, in this other general law, laid down in 1862 by Richard Cobden:

"From the moment the first shot is fired, or the first blow is struck, in a dispute, then farewell to all reason and argument; you might as well attempt to reason with mad dogs as with men when they have begun to spill each other's blood in mortal combat. I was so convinced of the fact during the Crimean War, which, you know, I opposed, I was so convinced of the utter uselessness of raising one's voice in opposition

to war when it was once begun that I made up my mind that as long as I was in political life, should a war again break out between England and a great power, I would never open my mouth on the subject from the time the first gun was fired till the peace was made, because when a war is commenced it will only be by the exhaustion of one party that a termination will be arrived at. If you look back at our history what did eloquence in the persons of Chatham or Burke do to prevent a war with our first American colonies? What did eloquence in the persons of Fox and his friends do to prevent the French Revolution, or bring it to a close? And there was a man who at the commencement of the Crimean War opposed it in terms of eloquence, in power, and pathos, and argument equal — in terms, I believe, fit to compare with anything that fell from the lips of Chatham and Burke — I mean your distinguished townsman, my friend Mr. Bright — and what was his success? Why, they burnt him in effigy for his pains."

Turning from the authorities and the lessons by them deduced from the record called history, let us now consider the problem precipitated on the American people by the Spanish war of 1898. The first and most important lesson is one which, in theory at least, is undisputed; though to live up to it practically calls for a courage of conviction not yet in evidence. That a dependency is not merely a possession, but a trust, a trust for the future, for itself, and for humanity, is accepted by us in this debate as a postulate. Accordingly, our dependencies are in no wise to be exploited for the general benefit of the alien owner, or that of individual components of that owner, but they are to be dealt with in a large and altruistic spirit with an unselfish view to their own utmost development, materially, morally, and politically. And, through a process of negatives, "all history shows" that only when this course is hereafter wisely and consecutively pursued, should that blessed consummation ever be attained, will the dominating power itself derive the largest and truest benefit from its possessions. As yet no American of any character, much less of authority, has come forward to controvert this proposition. But, assuming the correctness of the proposition I have just formulated, a corollary follows from it. A formidable proposition, I state it without limitations, meaning to challenge contradiction, I submit that there is not an instance in all recorded history, from the earliest precedent to that now making, where a so-called inferior race or community has been elevated in its character, or made self-sustaining and self-governing, or even put on the way to that result, through a condition of dependency or tutelage. I say "inferior race"; but, I fancy, I might state the proposition even more broadly. I might without much danger assert that the condition of dependency, even for communities of the same race and blood, always exercises an emasculating and deteriorating influence. I would undertake, if called on, to show also that this rule is invariable — that from the inherent and fundamental conditions of human nature it has known and can know no exceptions. This truth, also, I would demonstrate from well-nigh innumerable examples, that of our own colonial period among the number. In our case it required a century to do away in our minds and hearts with our dependential traditions. The Civil War and not what we call the Revolution was our real war of independence. And yet in our time of dependency you will remember we were not emasculated into a resigned and even cheerful self-incapacity as the natural result of a kindly, paternal, and protective policy; but, as Burke with profound insight expressed it, with us the spirit of independence and self-support was fostered "through a wise and salutary neglect." But, for present purposes, all this is unnecessary, and could lead but to a poor display of commonplace learning. The problem to-day engaging the attention of the American people is more limited. It relates solely to what are called "inferior races"; those of the same race, or of cognate races, we as yet do not propose to hold in a condition of permanent dependency; those we absorb or assimilate. Only those of "inferior race," the less developed or decadent, do we propose to hold in subjection, dealing with them, in theory at least, as a guardian deals with a family of wards.

What History Teaches.— My proposition then broadens. If history teaches anything in this regard it is that race elevation, the capacity in a word for political self-support, cannot be imparted through tutelage. Moreover, the milder, the more paternal, kindly, and protective the guardianship, the more emasculating it will prove. A "wise and salutary neglect" is the more beneficent policy; for, with races as with individuals, a state of dependency breeds the spirit of dependency. Take Great Britain, for instance. That people, working at it now consecutively through three whole centuries, after well-nigh innumerable experiences and as many costly blunders, Great Britain has, I say, developed a genius for dealing with dependencies, for the government of "inferior races"; a genius far in advance of anything the world has seen before. Yet my contention is that, to-day, after three rounded centuries of British rule, the Hindus, the natives of India, in spite of all material, industrial and educational improvements — roads, schools, justice, and peace — were in 1900 less capable of independent and ordered self-government, than they were in the year 1600, the year when the East India Company was incorporated under a patent of Elizabeth. The native Indian dynasties, those natural to the Hindus, have disappeared; accustomed to foreign rule, the people have no rulers of their own, nor could they rule themselves. The rule of aliens has with Hindustan thus become a domestic necessity. Remove it — and the highest and most recent authorities declare it surely will some day be removed — chaos would inevitably ensue. What is true of India is true of Egypt. Schools, roads, irrigation, law and order, and protection from attack, she has them all —

> "But what avail the plow or sail,
> Or land or life, if freedom fail?"

The capacity for self-government is not acquired in that school.

But of this England itself furnishes an example in its own history, an example well-nigh forgotten. In fundamentals human nature is much the same now as 20 centuries back. During the first century of the present era the Romans, acting in obedience to the law laid down by Mommsen — the law quoted by me in full, and the law of which Thomas Carlyle is the latest and

most eloquent exponent, the law known as the Divine Right of the most Masterful — acting in obedience to that law the Romans in the year of grace 43 crossed the British channel, overthrew the Celts and Gauls gathered in defense of what they mistakenly deemed their own, and, after reducing them to subjection, permanently occupied the land. They remained there four centuries, 100 years longer than the English have been in Calcutta. During that period they introduced civilization, established Christianity, constructed roads, dwellings and fortifications. Materially, the condition of the country vastly improved. The Romans protected the inhabitants against their enemies; also against themselves. During hundreds of years they benevolently assimilated them. Doubtless on the banks of the Tiber the inhabitants of what is now England were deemed incapable of self-government. Probably they were; unquestionably they became so. When the legions were at last withdrawn, the results of a kindly paternalism, secure protection, and intelligent tutelage became apparent. The race was wholly emasculate. It cursed its independence; it deplored its lost dependency. As the English historian (Green) now records the result: "They forgot how to fight for their country when they forgot how to govern it."

Man is always in a hurry; God never! is a familiar saying. Certainly, nature works with a discouraging indifference to generations. Each passing race of reformers and regenerators does indisputably love to witness some results of its efforts; but, in the case of England, in consequence of the emasculation incident to tutelage and dependency on a powerful, a benevolent, and beneficent foreign rule, after that rule ended — as soon or late such rule must always end — throughout the lives of 18 successive generations emasculated England was overrun. At last, with some half dozen intermediate rulers, the Normans succeeded the Romans. They were conquering masters; but they domesticated themselves in the British Islands, and in time assimilated the inhabitants thereof, Saxons, Picts, and Celts, benevolently or otherwise. But, as nearly as the historian can fix it, it required 800 years of direst tribulation to educate the people of England out of that spirit of self-distrust and dependency into which they had been reduced by four centuries of paternalism, at once Roman and temporarily beneficent. Twelve centuries is certainly a discouraging term to which to look forward. But steam and electricity have since then been developed to a manifest quickening of results. Even the pace of nature was in the 19th century vastly accelerated.

Briefly stated then, the historical deduction would seem to be somewhat as follows: Where a race has in itself, whether implanted there by nature or as the result of education, the elevating instinct and energy, the capacity of mastership, a state of dependency will tend to educate that capacity out of existence; and the more beneficent, paternal, and protecting the guardian power is, the more pernicious its influence becomes. In such cases the course most beneficial in the end to the dependency, now as a century ago, would be that characterized by "a wise and salutary neglect." Where, however, a race is for any cause not possessed of the innate saving capacity, being stationary or decadent, a state of dependency while it may improve material conditions, tends yet further to deteriorate the spirit and to diminish the capacity of self-government; if severe, it brutalizes, if kindly, it enervates.

CHARLES FRANCIS ADAMS,
Historian and Diplomat.

American Printing Trade. Although the printing trade had its inception in America considerably prior to the Revolutionary War, it was not until some time after the conclusion of that struggle for liberty that it began to assume the proportions of a national industry. In the year 1775, for example, there were less than 100 printing establishments upon American soil, and these were almost exclusively confined to the coast towns. Even as late as the year 1810 there were but 35 printing shops scattered about throughout the interior of the country, while, in 1775, with the exception of the two or three offices that were located in Massachusetts and Pennsylvania, the art of printing had no inland representation. A few years later a printing establishment was opened at Lexington, Ky.; another soon followed at Pittsburg, Pa., and the third office was finally located at Cincinnati, Ohio. In almost every instance these printing offices were established for the primary object of printing newspapers, although each of them not only possessed the necessary facilities for the production of jobwork, but were also able to print and bind books on the rare occasions upon which such contracts presented themselves.

From the earliest days in the history of the printing trade in America, New York, Philadelphia, and Boston have been the three great centers of this industry. Other seaport towns had their local shops, but the bulk of their business was small. In fact, during the first 50 years in the life of the new nation it was Philadelphia that took the lead in every branch of the printing industry, and, by the beginning of the 18th century the Quaker City presses, of which there were no less than 110 constantly in operation, were producing more English publications than any city in the world, with the single exception of London. It was here that Matthew Carey, the first great American publisher, established his plant, and with all its daily and weekly newspapers, and its book-printing and binding establishments, Philadelphia was indeed the most important center of the American printing trade.

Gradually, however, as the demands for printed works increased, other cities came into line, Albany, Hartford, and Worcester being among those that developed a comparative large trade. Their chief industry was in the printing of pamphlets. The newspapers of that day contained so little matter that they were easily read, and, as they were passed from man to man, their numerical circulation was extremely small. As the result, therefore, little effort was made to enlarge them, and persons who, like the politicians, wished to reach the general public were compelled to address themselves to the people through the medium of pamphlets. So far as actual literature was concerned the country was practically devoid of authors, and the books which were printed upon American presses were almost exclusively those which had been pirated from English publishers. Later some religious and technical books appeared, but it was many years before general literature began to display any marked degree of development.

In the beginning everything that was used

in the art of printing was imported from England. The American printers had English presses. It was from England that they obtained their type. Even the better qualities of printer's ink was imported, for the ink that was produced in this country was of such an inferior grade that it could be used only in the roughest kinds of jobs. From time to time various American printers made some slight improvements upon the old presses, but no great evidence of progress was shown until the establishment of a permanent type foundry.

Although it was the latter part of the 18th century before there was any permanent establishment for the making of type in this country, several attempts had previously been made to introduce such an innovation in the printing trade. As early as 1775 Benjamin Franklin had sent the complete equipment for a type foundry from Paris, but the attempt to establish this branch of the industry was not a financial success, and it was accordingly soon discontinued. Some ten years later a Scotch firm opened a foundry in Philadelphia, but it did not thrive, and the few other scattered efforts that were made to provide American workmen with American-made type met with the same fate. In 1796, however, two Scotchmen opened a type foundry in Philadelphia under the firm name of Binny & Ronaldson, and, as the time now seemed ripe for such an establishment, they were sufficiently successful to be able to continue operations. In 1805 another foundry was opened by the firm of Wing & White, in Hartford, but they found themselves unable to compete with the Philadelphia foundry until, in 1810, the establishment was removed to New York. Two years later the firm of David & George Bruce established a stereotyping plant in New York, and, when the already established foundries refused to supply them with type for their operations, they began to cast it for themselves, and soon became one of the most successful type-making houses in America. Their success, in fact, as much as the increasing demand for type, inspired others to follow their example. In 1816 a foundry was established in Boston; in 1817 another was opened in Baltimore, and, by 1830, there were no less than twelve foundries in full operation in various parts of the country. At the present time there are about thirty of these foundries in the United States, many of which are under the control of the American Type-Founders Company.

In the early days of the printing trade in America stereotyping was, of course, unknown, and the local publishers were accordingly compelled to recompose the type for each new edition that might be required. The introduction of stereotyping by the Bruces in 1813, therefore, suggested such economy that the enterprise could scarcely have failed to meet with favor at the hands of the printers. While the plaster process, the first method of stereotyping in vogue, was invented in England by Lord Stanhope, tidings of this great discovery were soon brought to this country, and David Bruce at once set sail for the old world for the express purpose of securing the information that would enable him to make practical use of the new invention in America. Although the stories that had reached this country had pictured the new discovery as a perfected invention, Lord Stanhope's experiments had actually by no means been concluded, and, as the result, Bruce found it impossible to acquire anything more than the most superficial knowledge concerning the process. Finding that all material facts were being withheld from him, and that it would be useless to attempt to persuade Lord Stanhope to disclose his secret, Bruce returned to the United States. So far from admitting his defeat, however, he promptly went to work, and, with the little information he had obtained, he managed by his own genius and mechanical skill to make a plate that was in every respect superior to any that had as yet been cast in England. Through his own diligence he had mastered the defects which Lord Stanhope had been unable to overcome, for his plate was not only perfectly level on both sides, but it was of uniform thickness in every part. In fact, so successful was he that an Englishman named Watts, who had succeeded in learning his process, went back to Europe with his knowledge. There he found scores of master-printers who, disgusted with the English invention, were glad to be taught how the American plates were made, and it was through his efforts that both Austria and Germany acquired the art of stereotyping.

From the day on which David & George Bruce opened their foundry in New York they had all the orders that they could fill, for American publishers were quick to appreciate the economical advantage of the new invention. It was the time when the public was just beginning to demand books, and as the plaster casts were not only made without great expense but also guaranteed plates of great durability, printers were eager to stereotype all books that might by any possibility require a second edition. From this simple beginning, therefore, came the great stereotyping industry of America. By 1850, the year in which the making of plaster plates attained its greatest development, there were more than 50 firms engaged in this business in the United States, while more than 1,000 men were employed in the work. Then came the modern improvements — the electrotyping for book-work and the introduction of the papier-mache process in the making of newspapers — since which time the making of plates has become practically an art by itself.

Prior to 1805 comparatively little printer's ink was made in this country. Although printers were supposed to know how to mix the compound, the preparations that they concocted proved such a poor substitute that all the good inks were imported. In 1805, however, two firms — one in Philadelphia and the other in Cambridgeport — began the manufacture of printing ink, and, since that time, the industry has been steadily extended until there are now about 35 firms engaged in this branch of the printing trade. About 1860 the cheapness of aniline colors inspired a more general use of colored inks, but as many of these tints soon lost their brilliancy they did not become very popular until the chemists had succeeded in correcting this fault.

The period between 1810 and 1833 witnessed many great improvements in the art of printing. One of the most important innovations was the substitution of iron for wood in the making of hand presses. Although wooden presses had been used since the time of Gutenberg they had always proved a handicap to good printing.

Even the strongest wood was weak, and as the machine was liable to give way in some part at any pull, the pressmen found it impossible to obtain a good impression, even when the type surface was no larger than 12 by 20 inches. As the natural result, all hand-presses were small affairs, and as they required the services of two expert workmen to keep them going the process was as costly as it was slow. In the adoption of the iron press American printers followed the example of their English brethren. The first iron press to be made in America was completed about 1820, but, sometime previous to that date, such presses had been imported from England. Recognizing the advantage of a machine that was capable of printing a sheet three times as large as the old press and with no greater muscular effort, American printers soon demanded them, but, in spite of this demand, it was several years before the wooden presses were relegated to the junk-heap, some of them having been in use, even in New York, as late as 1850. In the beginning presses were made by Turney, Worrall, Wells, and Smith, but gradually the business began to center with Hoe in New York and Ramage & Bronstrup in Philadelphia, until, finally, nearly all the presses were manufactured by these houses.

Another invention that proved an invaluable aid to the progress of the art of printing was the making of elastic rollers for inking the type. The original method of inking was a most laborious system, the application of the ink being made with balls of pelt. Early in the 19th century, however, an English compositor discovered that a composition of glue and molasses, long used in the making of pottery, could be applied in the inking of type, and from this idea was evolved the composition roller which was so necessary to the success of the first machine presses. This roller was first employed in this country about 1826. Another invention that played an important part in the production of cheap printing was the improved method of paper manufacture which came with the introduction of Fourdrinier's machine. This, too, was introduced in America soon after 1826, and, since that time the growth of the printing industry has been a steady and rapid evolution.

Of course, the great necessity under the new conditions was more rapid printing facilities, and this demand was met by the inventors about 1829. Some 15 years prior to that time a German printer named Konig went to England to produce a cylinder machine for the use of the London *Times*. While the press that he constructed was rather successful, he returned to Germany before it was perfected, leaving the English inventors to complete the improvement of his work. This they did in many respects, but the credit for the first actual success in the making of cylinder presses is due to the American manufacturers, firms like R. Hoe & Co., who took the somewhat unsatisfactory foreign machines and brought them to a state of comparative perfection. By depending only upon good material and thorough workmanship they produced cylinders that were so much more satisfactory than the foreign goods, that, in spite of the fact that the home product is cheaper, English printers have long found it expedient either to import American printing machines, or to make their own presses from American models.

After 1833, therefore, America needed no further help from England in the development of her printing industry. With the best of paper, ink, type, and presses, all made in this country, and with plenty of money to invest in manufacturing enterprises connected with this trade, it was unnecessary for her to turn to any foreign nation for assistance, and when, in 1830, the system of cloth book-binding was introduced, all the requisites for literary progress were in her own hands.

Of course, with the development of the power press the character of the newspapers of this country also began to change. Whereas they had originally been small and dull, having but little news in them, the ability to print many copies enabled them to increase their circulation as well as their size. In 1833 the New York *Sun*, printing a sheet 11½ by 17 inches on a hand press, could not produce more than 400 copies an hour. As the demand for the paper continued to increase, however, a cylinder press, propelled by a man at a crank, was introduced in 1834, and a year later, this was supplanted by a double-cylinder operated by steam power. As other papers in other parts of the country met with similar experiences, the demand for rapid newspaper presses continued, and, by 1845, it was found that even the double-cylinder machine was too slow for the requirements of the constantly growing circulation of the great dailies. See American Newspapers.

It was to comply with this demand that R. Hoe & Co., in 1847, invented the type-revolving rotary printing press, a machine in which the type was fastened to the cylinder and successively presented to each of the impression cylinders placed around it. For more than 20 years this press was able to meet every demand of periodical publications, but, in 1869, finding that it had at last become too slow, R. Hoe & Co. perfected their web-printing machine, a press which prints continuously from stereotyped plates on a cylinder against an endless roll of paper. In spite of the almost incredible speed at which this press can be run, other inventions, which have since been perfected, now enable it, not only to print 4, 8, 12, or even more pages, but at the same time, to fold, count, and paste them; to insert sheets or add the necessary covers, or even to print illustrations in many colors. In 1854 William A. Bullock perfected the first cylinder machine that was capable of printing a newspaper from a roll on both sides at the same time, but the other improvements have been the work of R. Hoe & Co., or some of their business rivals like Cottrell, Babcock, Campbell, Potter, Huber, Miehle, Joss, and others.

Great as has been the improvement in the making of machine-presses, however, the other branches of the art of printing have succeeded in keeping pace with it. In stereotyping, for example, the invention of the papier-mache process enabled printers to make a number of impressions of the same page of type, while the demand for a convex plate was met, in 1854, when Charles Craske, of New York, succeeded in stereotyping a curved surface.

The period between 1833 and the outbreak of the Civil War also witnessed many improvements in the art of printing, the most important being the introduction of fast printing in fine book and job work. The invention of the power

press had been a blessing to the newspapers, but, for a long time, book and fine job work was still done on hand presses. It was not until 1836 that Harper & Brothers introduced a power-press, although Daniel Fanshaw of New York, the printer of the Bible Society, had 10 power printing machines in operation in his shop prior to that time. These machines were manufactured by Daniel Treadwell of Massachusetts, and, although they were both bulky and inconvenient, they were the best presses on the market until the Adams press came to take their place. During all this period, however, it was believed that cylinder machines were incapable of doing fine work, and it was not until Francis Hart, of New York, had demonstrated the fallacy of this theory that the incredulous could be persuaded to make the change which the proper development of the trade had so long demanded.

To Joseph A. Adams belongs the credit of devising the American method of making-ready woodcuts, and he it was who first demonstrated the feasibility of the new process of electrotyping by making successful electrotype plates, in 1839. It was in 1838 that the type-casting machine was invented by David Bruce, and about 1850 that the method of printing illustrations on dry paper was discovered.

The art of engraving on wood was practiced until comparatively recent times, but the introduction of the art of photo-engraving destroyed its usefulness, for, while wood engravings were extremely costly, the new process made the cheapest of illustrations possible. Lithography, or the art of printing upon stone, has been employed in the United States since 1819. It was not until 1825 that its use became commercially practicable, but, since that time, this form of printing has developed so rapidly that, in 1904, the amount of such work done was estimated to be nearly $40,000,000, a production which required the employment of more than 9,000 persons.

One of the latest, and, unquestionably, one of the greatest improvements in the art of printing was the invention of the typesetting machine, which is now in such general use in all large establishments that it may be said to have practically supplanted hand composition. It is by such inventions, however, that the printing trade has been revolutionized until it has grown from the small proportions of a business which engaged the attention of less than 500 men to a great national industry, in which the capital invested, according to the 1904 estimate, is in excess of $300,000,000, that has an annual output that is valued at more than $350,000,000, and which gives employment to not less than 175,000 persons. ALBERT BUCKLEY NICHOLS,

The Herald Company of Binghamton.

American Protective Association, or "A. P. A.," a secret order organized throughout the United States and Canada. Its chief doctrine, as announced in its declaration of principle, is that "subjection to and support of any ecclesiastical power not created and controlled by American citizens, and which claims equal, if not greater, sovereignty than the government of the United States of America, is irreconcilable with American citizenship"; and it accordingly opposes "the holding of offices in national, State, or municipal government by any subject or supporter of such ecclesiastical power." Another of its purposes is to prevent all public encouragement and support of sectarian schools. It does not constitute a separate political party, but seeks to control existing parties, and to elect friendly and defeat objectionable candidates by the concerted action of citizens affiliated with all parties, much after the style of the American or "Know-Nothing" party. The order was founded 13 March 1887, and in 1900 claimed a membership of over 2,000,000.

American Psychological Association, a society founded in 1892 for the advancement of psychology as a science. Persons are eligible to membership who are engaged in this work. Membership, 135. Office of secretary, Columbia University, New York.

American Publishing. The book trade or publishing industry in the New World had its origin in a more remote period than is generally supposed. It began within 100 years of the invention of printing, and from the date of the first American book, 1535, to the year 1799, over 7,000 different books had been published, nine tenths of them however being pamphlets. The 19th century saw almost the full development of book publishing, the establishment of colleges and schools and the founding of many libraries, creating an ever-increasing demand for the best in literature.

Early American Books.— The first book printed on the American continent is said to have been "La Escalera Spiritual de San Juan Climaco," published in Mexico in 1535. It was a translation from the Latin into Castilian. Other books were printed on the first press set up in Mexico and six or seven books are known to have been published in Peru before 1600. In the United States the earliest publication was a pamphlet called "The Freeman's Oath," printed in Boston in 1639. This was followed in the year 1640 by the "Bay Psalm Book," printed by Stephen Daye at Cambridge, Mass. After its publication in the colony it was reprinted in England, where it went through 17 editions, the last one bearing the date of 1754. It was also a highly popular work in Scotland, 22 editions having been printed there, the last dated 1759. The first original American book published in this country was Mrs. Anne Bradstreet's "Poems," and this volume, issued in Cambridge, Mass., in 1640, was republished in London in 1650. Cambridge remained the only publishing town for a long time, and for 21 consecutive years issued about one volume a year. In 1653 Samuel Green published John Eliot's famous "Catechism" in the Indian language, followed in 1659 by the Psalms in Indian, in 1661 by the Indian New Testament, and in 1663 by the whole Bible in the Indian tongue. This was the first Bible printed in America.

Early Publishers.— In New York city the original book publisher was William Bradford, who became official printer in 1693, for "40 pounds a year and half the benefit of his printing, besides what served the public." In 1694 he issued the "Laws of the Colony," the first bound book published in New York. In 1738, Christopher Sauer established a publishing house at Germantown, Pa., and issued the first German Bible printed in America in 1743. The firm of Little, Brown & Company was estab-

lished in 1784 in Boston while in the following year in Philadelphia, Lea Brothers & Company and Henry Baird & Company began business. It was also in 1785 that S. E. Bridgeman & Company began publishing books at Northampton, Mass. The existing house of J. B. Lippincott & Company was established in Philadelphia in 1798. The firm of Harper & Brother began business in New York in 1817. From this date the publishing business had a rapid growth, among the firms established being the following in New York: Baker, Voorhis & Company, 1820; D. Appleton & Company, 1825; D. Van Nostrand, 1830; Ivison & Company, 1831; John Wiley & Sons, 1832; John F. Trow, 1835; A. S. Barnes & Company, 1838. In other cities the early firms included the following: Cincinnati, O., U. P. James, 1831; Springfield, Mass., G. & C. Merriam Company, 1831; Louisville, Ky., John P. Morton, 1825; Richmond, Va., J. W. Randolph Company, 1831; Mobile, Ala., G. H. Randall, 1831; Montgomery, Ala., Joel White & Company, 1833; Lancaster, Pa., John Baer's Sons, 1817.

The Early Book Trade.— As an adjunct to publishing, the selling of books originated in Boston as early as 1652, when Hezekiah Usher opened the first shop. Many colonial booksellers printed and published their wares. Benjamin Franklin (q.v.) was among the early book printers. In 1732, Richard Fry, an Englishman and bookseller of Boston, advertised: "Whereas it has been the common method of the most curious merchants of Boston to procure their books from London, this is to acquaint these gentlemen that I, the said Fry, will sell all sorts of accompt books, done after the most acute manner, for 20 per cent cheaper than they can have them from London. * * * For the pleasing entertainment of the polite parts of mankind, I have printed the most beautiful poems of Stephen Duck, the famous Wiltshire poet. It is a full demonstration to me that the people of New England have a fine taste for good sense and polite learning, having already sold 1,200 of these poems." The first convention of booksellers for the regulation of trade seems to have been held in Boston, 1724; it was for the special purpose of increasing the prices of certain works. Toward the close of the century bookselling began to take rank among the most considerable commercial pursuits, though it then only foreshadowed its present comparative importance. Works of standard character, involving large expenditures, were undertaken by publishers, who, in such cases, usually subscribed together as a guarantee for the printer's outlay. The trade was conducted upon established principles, and innovators were held in poor esteem. All these usages were, however, disturbed by competition, and after the publication of the Waverly novels, of which rival editions were issued, the individual members of the trade acted more independently of each other, and their customs afterward partook of a less narrow spirit. The American company of booksellers was founded in 1801. Books were formerly sold in sheets, to be bound as purchasers might desire, a practice which no longer obtains. The universal diffusion of education in America, and the inquiring mental character of its people, not only increased the circulation of books but reduced their price, and the old-fashioned veneration which literary works had once inspired experienced no little modification. Externals were of small consequence to the great body of readers, and works were purchased not so much for preservation as for immediate reading.

Statistics.— From 1825 to 1840 the number of American publications show an aggregate of 1,115. Of these 623 were original and 492 were reprints from foreign works. The population of the United States in that year was about 17,000,000. In 1853, 733 new works were published in the United States, of which 278 were reprints of English works, 35 were translations of foreign authors, and the remainder were original American works. The population of the United States had reached about 25,000,000, an increase of 50 per cent compared with 1840. The original American works published in 1853, compared with the 15 years ending in 1840, show an increase of about 800 per cent in less than 20 years. In other words, the original American publications of the book trade seem to have advanced about 15 times as fast as the population. In 1880, with a population of 50,000,000, the new books published during that year amounted to about 2,000 — nearly three times more than in 1853, whereas the population had only doubled. The total number of new books published in each year, according to the records of the "Publishers' Weekly" from 1881 to 1903 inclusive, were as follows:

NEW BOOKS PUBLISHED.

1881	2,991	1893	5,134
1882	3,472	1894	4,484
1883	3,481	1895	5,469
1884	4,038	1896	5,703
1885	4,030	1897	4,928
1886	4,776	1898	4,886
1887	4,437	1899	[illegible]
1888	4,631	1900	[illegible]
1889	4,014	1901	8,141
1890	4,559	1902	7,833
1891	4,665	1903	7,865
1892	4,862		

Included in these figures are different editions of the same book issued by different publishers. The total for 1903, of 7,865 books includes 2,072 new editions. Of the new books, 5,621 were by American, 1,356 by English and other foreign authors. The 888 books required to make up the total of 7,865, were imported "in sheets," i. e., they were printed abroad, and bound in this country. Fiction leads, with 977 American and 483 foreign books. Law comes next with 605 titles, all but three American; education holds third place, (627 titles) and religion and theology fourth, with 513 titles. The output for 1902 and 1903 may be compared as follows:

	1902.	1903.
Fiction, American	903	977
Fiction, Foreign	818	483
Law	622	605
Education	408	627
Theology	433	513

A more detailed classification of the output of books in the United States during a single

year will be found in the report for 1902, as follows:

BOOK PUBLICATIONS FOR 1902.

Classes	Copyright books by American authors including new editions.	Books by English and other foreign authors including new editions.	Books in English imported in editions.
Fiction	903	818	76
Law	622	2	16
Juvenile	388	39	87
Education	408	108	63
Theology and religion	433	78	128
Political and social science	223	8	40
Biography, correspondence	253	37	95
History	178	59	64
Poetry and drama	220	130	49
Literature and collected works	311	136	96

Works of reference	98	2	11
Totals	5,210	1,578	1,045
			1,578
			5,210
Grand total			7,833

Popular Books.— In 1903 there were 1,700 book publishers in the United States. While Boston and Philadelphia remain true to their earlier reputations as leading book centres, New York has become the largest book mart and the leading factor in the manufacture of books. Chicago too has assumed an important place in the book trade, while some hundreds of books are published annually in Cincinnati, San Francisco, Cleveland, and other smaller cities. The majority of American books are published by 100 firms in New York, Boston, Chicago, and Philadelphia. During 1902 and 1903 the historical novels enjoyed widespread popularity, and nine books of this class circulated to the extent of 1,400,000 copies. This enormous output, however, did not lessen the sale of older and more standard books. These were largely reprints. A popular work 75 years after its first publication is often found to have been reprinted 20 times by as many different publishers. Of the world's great standards, hundreds, and in some cases thousands, of editions have appeared. There is, nevertheless, a distinction to be made between the manufacturer of books who takes old works and reprints them, and the publisher who issues entirely fresh and original matter. Among early successful books Mrs. Stowe's "Uncle Tom's Cabin" had a phenomenal sale, 500,000 copies being sold in less than five years in the United States, and by April 1852 more than 1,000,000 had been reprinted in Great Britain. Of Longfellow's poems, without taking into account unauthorized English reprints, the American sales in 1839-57 amounted to 325,550; from the latter date till 1901, 220,000.

School Books.— No small factor in bookmaking during the 19th century was the phenomenal production of school and college textbooks. In fact, the publication of educational works has increased steadily. In 1902 the reports showed a list of 433 educational works, while in 1903 this was increased to 607. This is illustrative of the remarkable growth in schoolbook publishing. Of books for use in the public schools editions of 500,000 copies, intended for one year's consumption, are not an unusual event. Messrs. D. Appleton & Company for many years sold over 1,000,000 copies of Webster's "Speller" every year; and W. B. Smith & Company, of Cincinnati, Ohio, sold over 1,000,000 copies of the Eclectic Series during each year. The electrotype plates of schoolbooks, Bibles, prayer-books, and hymn-books, are very rarely changed, and enormous quantities are sold every year.

Miscellaneous Books.— In the United States many encyclopedias, dictionaries, the complete works of standard authors in definitive editions, anthologies of literature, etc., are sold by subscription; and the initial expense of such books being enormous, before a single copy of the book is made, the sales must be enormous also. Then there are many "books which are not books" — such as city directories, which are usually published by a company devoted exclusively to the publication of this one book; State directories, list of dealers in each business, and commercial agency reports (each of these agencies makes four revised editions of its books each year, each book measuring about 11x13 inches, and containing about 2,500 pages of matter in close print. There are also innumerable genealogies, indexes, catalogues, together with many other productions which are truly books, but which cannot be called literature.

Commercial Value.— In the publishing of books the following are the items of outlay which need to be taken into account: Copyright, paper, typesetting, author's corrections, electrotyping, press work, binding, advertising. Publishing means a great deal more than merely printing and binding a book. It means putting it where it is likely to sell. The machinery of distribution, which means the method of getting books finally into the hands of readers through the various middlemen, is vastly important. The manufacture of a book now demands the assistance of various branches of mechanical skill. Besides the paper-maker, the type-founder, and the printer, to whom it gives a large proportion of employment, it engages, exclusively, the bookbinder. Its material form has, till the present era of cheap publications, always borne a commercial value extravagantly disproportionate to its matter.

Copyright.— A common arrangement between the American author and publisher is a payment of 10 per cent royalty on the retail price of all sales; sometimes a cash sum is paid, and the publisher secures the copyright, which is granted for 28 years, subject to renewal by the author, his widow, or children for other 14 years. A condition is that a copy of a title-page must be registered with the librarian of Congress, and two copies of the book lodged there within ten days of publication. The entry fees are 50 cents for an American author, $1.00

AMOUNT OF MATERIAL CONSUMED ANNUALLY IN THE UNITED STATES IN THE MANUFACTURE OF BOOKS AND PERIODICALS.

for a foreigner, and 50 cents additional for a certificate of record. A copy of any new edition must also be sent to the librarian. (See COPYRIGHT.) By the provisions of the International Copyright Act (1886), a foreign author's rights are protected in Great Britain, Belgium, France, Germany, Hayti, Italy, Spain, Switzerland, and Tunis. Colonial authors can also secure copyright without publication in the United Kingdom, and a work copyright in the United Kingdom is copyright in Canada. American cheap reprints of British books are admitted to Canada subject to a customs duty of 12½ per cent, to be paid over to the British author, but the returns from this source have been very small.

Bookbinding.— Since 1885, in the book-making industry, many improvements have been made in wire-stitching machines. One of these machines will stitch anything from two sheets to a book two inches thick, and with several of them either round or flat wire may be used. There has also been introduced a noteworthy combination folding and wire-stitching machine, which, by a continuous and automatic operation, takes the sheets from the feeders, and folds, gathers, collates, covers, and wire-stitches them. Paper-cutting machines have been improved by the introduction of automatic clamps, indicators, and gauges. The invention of a steam rounding and backing machine has increased the capacity of from 500 to 1,000 books per day to a capacity of from 5,000 to 6,000 in the same time. The latest case-making machine feeds itself from a roll of cloth which it automatically cuts into pieces of proper size for use. The cloth is first covered with glue by contact with a cylinder revolving in a pot of glue. It is then cut by the machine and nicked in corner sections; boards are supplied from a holder and a back lining from a roll, both receptacles forming part of the machine. This process completed, the nearly finished product drops a little, the cloth is folded over the boards and back lining, and the binding, after passing through a case smoother, is delivered in a finished state. Among other inventions are a casting-in machine, for putting the body of a book into its cover, and a gathering machine. This latter invention promises important developments in economy.

Book Plates.— About the year 1804 the art of stereotyping was invented in England, and in a few years was introduced into this country. With the type-printed book under the old conditions a publisher did not dare print a large number of copies of any book unless he believed it would have a quick sale. Books were bulky, and took up too much space. Consequently, the types for a first edition were distributed when they left the press; then had to be reset with renewed chances of error in the second edition. Resetting for two or more editions added largely to the cost of the book and limited its supply. The process of stereotyping first used, known as the plaster process, served book printers for about 50 years. The practice of the art was brought to New York by David Bruce in 1813, but the first book stereotypes in America was the «Westminster Catechism.» made by J. Watts & Co. of New York in June of the same year. For the printing of books, all methods of stereotyping have been superseded by electrotyping, which was experimentally tried in New York as early as 1841, and was in general use before 1855.

Book Imports.— The summary of imports of books and other printed matter for 1902 and 1903 shows the following:

(FREE OF DUTY.)

Imported from	1902	1903
United Kingdom	$1,057,909	$1,327,75c
France	174,326	167,965
Germany	615,140	623,889
Other Europe	379,047	264,037
British North America	42,091	33,563
Other Countries	20,379	21,658
Totals	$2,288,802	$2,438,862

(DUTIABLE.)

Imported from	1902	1903
United Kingdom	$1,112,017	$1,181,049
France	76,201	82,800
Germany	261,464	307,961
Other Europe	83,059	96,381
British North America	48,228	46,127
China	3,308	3,728
Japan	15,256	21,117
Other Countries	5,869	5,266
Totals	$1,605,402	$1,744,159

The total imports for 1903 amounted to $4,183,021 as against $3,894,204 for 1902.

Book Exports.— The books and other printed matter of domestic manufacture exported from the United States during 1902 and 1903 represent the following:

Countries to Which Exported	1902	1903
United Kingdom	$1,094,341	$1,102,248
Belgium	25,184	27,251
France	70,143	49,852
Germany	199,060	193,125
Italy	17,317	27,038
Netherlands	11,695	10,735
Other Europe	35,867	33,294
British North America	1,362,903	1,557,331
Central American States and British Honduras	19,475	15,978
Mexico	220,129	152,409
Cuba	70,134	80,864
Other West Indies and Bermuda	31,517	32,316
Argentina	35,232	40,011
Brazil	30,927	40,199
Chili	44,488	37,582
Colombia	36,612	10,237
Venezuela	19,700	3,499
Other South America	47,115	61,951
Chinese Empire	30,740	25,750
British East Indies	29,796	22,826
Japan	59,897	50,083
British Australasia	239,677	191,031
Philippine Islands	140,881	52,159
Other Asia and Oceanica	23,258	20,698
British Africa	109,293	50,164
All other Africa	11,465	9,979
Other Countries	....	34
Totals	$4,016,845	$3,911,634

During the decade 1894 to 1904 the only striking change recorded in the book-publishing trade was the enormous and phenomenal circulation of a dozen popular novels. During this

period the advance in good taste and in artistic beauty of product was a marked characteristic of the industry. Fashions in bindings changed annually, but a widening range of materials and patterns, more daring use of designs and inks, and the invention and general use of automatic binding machinery supplemented improvements in printing, permitting lower prices for books and promoting phenomenal sales. It is a significant coincidence that the decade which witnessed extraordinary advance in all details of mechanical productions in this industry should be characterized also by the most noteworthy advance in the good taste and appreciation of the general public.

American Quarrying. See Quarrying.

American Railroads. The first railroads in the United States were built to carry stone, gravel, anthracite coal, and other heavy materials. These of necessity were short. One was built on Beacon Hill in Boston, in 1807; one in Delaware County, Pa., in 1809; and one at Bear Creek Furnace, Armstrong County, Pa., in 1818. Other short roads were simultaneously constructed, all having tracks composed of wooden rails. In 1812, Col, John Stevens, of Hoboken, N. J., issued a pamphlet stating "that trains of carriages would be drawn on railways at 20 or 30 miles an hour," and further said, "I can see nothing to hinder a steam carriage from moving on these rails with a velocity of 100 miles an hour." This was a daring prophecy; but in 1827 the Delaware & Hudson Canal Co. began the construction of the Carbondale R.R., extending from Hohendale, Pa., to Carbondale, a distance of 27 miles. Horses were the motive power for drawing the cars which were used in transporting coal from the mines to the canal. In 1828 this company sent Horatio Allen, a machinist and civil engineer, to England to purchase iron rails, and to order 3 locomotives of such pattern as he might determine upon after his arrival in England. The first of these made its trial trip on 9 Aug. 1829, and was the first locomotive ever run in America. Mr. Allen ran the engine himself, and would permit no one else on it, as he considered the risk of life and limb too great.

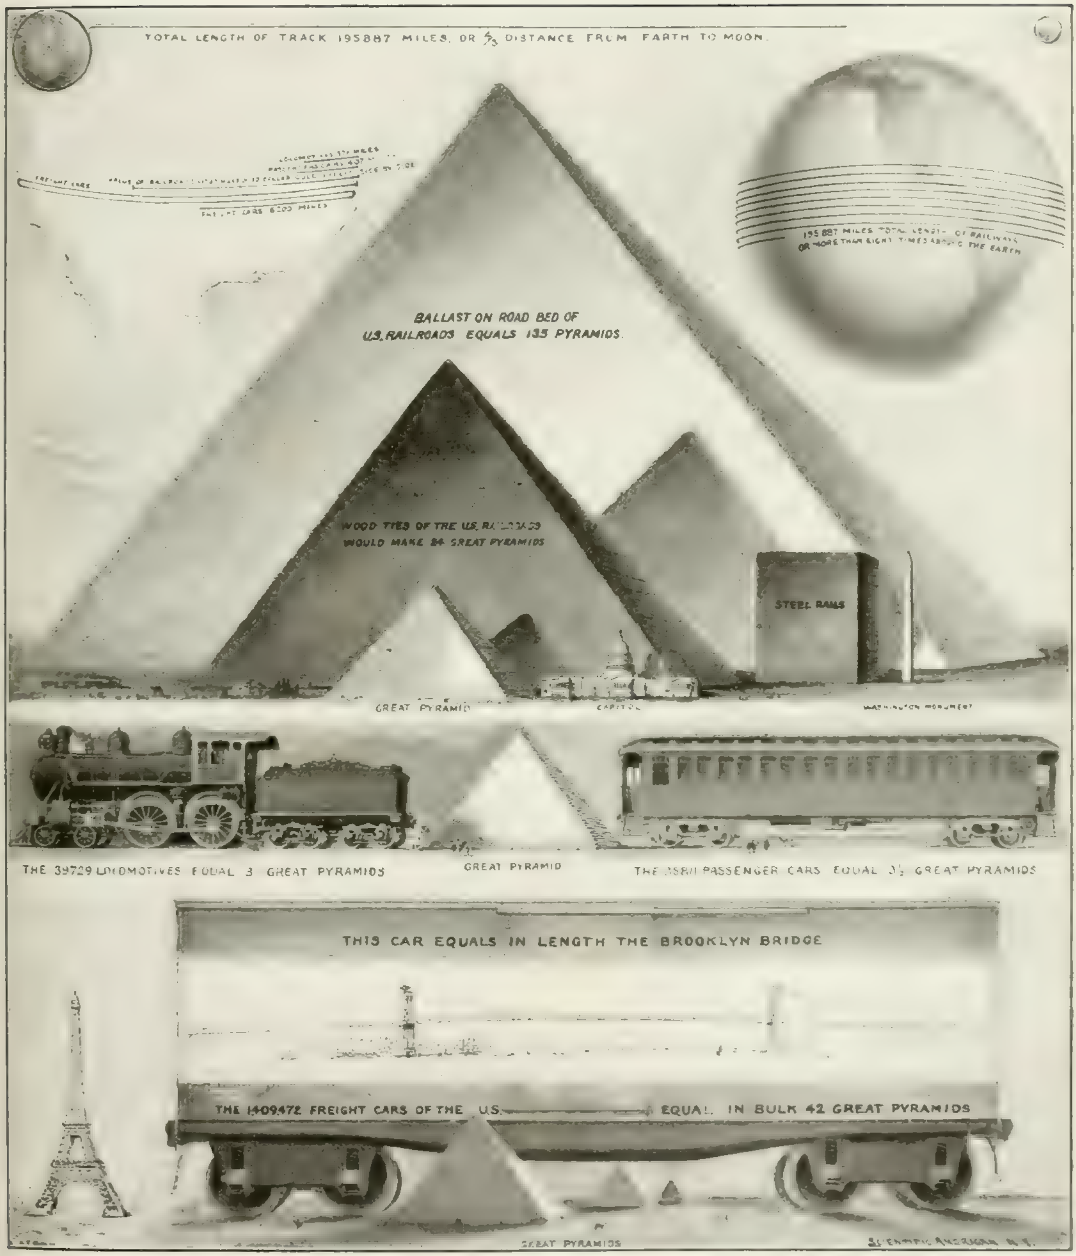
The Baltimore & Ohio R.R., the first undertaking to transport passengers, was projected in 1828, constructed in 1829, and opened for business from Baltimore to Ellicott Mills, 15 miles, in May, 1830. Horses were used, and where the change of teams was made, gave rise to the well-known relay station 9 miles from Baltimore. In 1830, Peter Cooper built a locomotive, the first ever constructed in the United States, and congratulated himself that he made better time than the horses on the Baltimore & Ohio R.R. This engine weighed less than a ton, the boiler was about the size of a flour barrel, and the flues were made of gun barrels.

In 1830 there were but 23 miles of railroad in use. During the succeeding 10 years the total mileage reached 2,818. The line from Albany to Schenectady, 17 miles, was opened in 1831. Five years later Albany and Utica had rail connection, and in 1842, Buffalo was reached. In the meantime lines had been built from New York and Boston to Albany, so that the then East and West were in easy communication by way of the railroads and the Great Lakes. In the year 1850, the length of the railroads in the United States aggregated 9,021 miles; in 1860, 30,635 miles; in 1870, 52,914 miles; in 1880, 93,296 miles; in 1890, 163,597 miles; in 1900, 193,346 miles. The present mileage of the railroad systems of the United States, in excess of 200,000, only partially indicates their magnitude, when it is remembered that the present total value of railroad assets ($13,000,000,000) is about one-seventh of the total present wealth of the United States ($90,000,000,000).

There are about 1,000 operating railroad companies in the United States; but the railroad system of the United States is conveniently divided into 7 groups, each group occupying a nearly distinct section of the country, the basis of the grouping being found in differences in production, density of population, and various social and ecomonic conditions prevailing in the 7 sections of the country. In each of these sections there is considerable unity in the operation and ownership of the railroad systems. These territorial groups are as follows: (1) The New England States; (2) the region west of New England and the middle Atlantic seaboard, north of the Ohio and James rivers, and east of Chicago and Saint Louis (trunk line territory); (3) the section south of the Ohio and James rivers and east of the Mississippi (southern territory); (4) the region west and north of Chicago and Saint Louis, including the chief grain-raising States of the United States (granger territory); (5) south and west of Saint Louis (southwestern territory); (6) west of the granger and southwestern territories (trans-continental or Pacific lines); (7) a subdivision of lines within the trunk-line territory whose business consists chiefly of transporting anthracite coal from the Pennsylvania mines to the seaboard.

This grouping of the American railroads into 7 systems, based upon physical differences in territory and economic conditions, is not entirely satisfactory, as it gives little or no information regarding ownership and management. A grouping along this line would be as follows: (1) The Boston & Maine, 3,283 miles; (2) New York, New Haven & Hartford, 2,027 miles; (3) the Vanderbilt roads, 20,798 miles; (4) the Pennsylvania system, 19,301 miles; (5) the Philadelphia & Reading system, 2,145 miles; (6) Morgan roads, 11,229 miles; (7) Morgan & Atlantic Coast Line Company roads, 10,071 miles; (8) Illinois Central, 5,380 miles; (9) Seaboard Air Line, 2,611 miles; (10) Gould roads, 15,504 miles; (11) Moore roads 13,003 miles; (12) Chicago, Milwaukee & Saint Paul, 6,604 miles; (13) Chicago Great Western, 956 miles; (14) Hawley roads, 2,376 miles; (15) Wisconsin Central, 978 miles; (16) Harriman roads, 16,468 miles; (17) Morgan-Hill roads, 24,711 miles; (18) Atchison, Topeka & Santa Fé, 7,876 miles. This classification, subject to constant change by transfers of ownership, shows that four-fifths of the railroad mileage of the United States is now in the hands of a few large interests and capitalists, between whom there is developing a community of interest or harmony of action that is restraining competition in rate-making.

The United States government has sought to supervise or regulate the entire business of rail transportation in order to establish and maintain equitable relations between the carriers and



RAILWAY STATISTICS OF THE UNITED STATES.

the people served. This result cannot be attained solely by statutory prohibitions. In America, laws to be enforced must give expression to public opinion and in order to make unjust discriminations impossible, the public must declare that it is as much a crime for public carriers to deny to one individual or community advantages to which they are justly entitled, as it would be for the government to show favors to some citizens, and discriminate against others. The problem is a continuing one, the specific necessity for government regulation varying from time to time. In 1870 it was necessary to secure cheaper rates to the seaboard for the agricultural products of the Central States; during the period from 1870 to 1890 it was necessary to adjust the rates charged at small local towns and large cities; at the present time it is imperatively necessary to secure relatively reasonable rates for rival areas of production and for rival economic interests in the same area of production. In the last few years new ideas have led to the betterment of railroad management and operation and the railroad personnel has been educated to a high standard. The system of to-day is a development resulting from 75 years of experience. From the first crude plant by gradual stages has been evolved the modern economical transportation machine of to-day. From the first crude rate sheet has been evolved the present successful, if complicated scheme of charges, successful because it moves the traffic to the satisfaction of the shippers, the benefit of the country at large, and produces a profit to the corporation owning the properties. See RAILWAY SYSTEMS, AMERICAN.

EDWARD S. FARROW,
Consulting Railroad and Mining Engineer.

American Republics, Bureau of. The Pan-American Congress held in Washington in 1889, though ostensibly convened merely to consider arbitration and the improvement of commerce between the republics of the western hemisphere, had a much broader object in view: to express in practical form the solidarity of American interests, and devise means to protect them. Believing that a closer union between us is possible only through confidence born of closer intimacy, the Congress created the International Union of American Republics and organized the Bureau of American Republics (with a supervisory International Executive Committee) to effect that purpose.

The Bureau's original function of publishing tariff data, port regulations, trade statistics, etc., was soon extended to the diffusion of all sorts of exact knowledge concerning the American republics, showing their natural solidarity and mutual protective necessities. To this end it publishes a monthly bulletin in English, Spanish, Portuguese, and French, now in its 11th volume; handbooks to the Central and South American states; their tariff, immigration, and other laws of general interest, and a great variety of information otherwise inaccessible on their commerce, industries, and general conditions; also an alphabetical code of commercial nomenclature in parallel English, Spanish, and Portuguese columns comprising over 50,000 dutiable commodies, for the use of customs and consular officers and shippers. In 1000 it began compiling from the best sources special large-scale maps of various republics, containing all economic data, lines of rail and wire, mines, areas of cultivation, etc. As a further instrument it has built up a library of 'American' of nearly 10,000 volumes, and a valuable collection of maps and photographs, in the subject-catalogues of which are noted all the works and articles on America, and cognate maps, in Washington libraries. It also receives all official documents published by American countries.

American Revolution. See UNITED STATES — AMERICAN REVOLUTION.

American River, in north central California, is formed by the union of its northern and southern forks near the western boundary of the county of El Dorado, whence it flows southwest between the counties of Placer and Sacramento and falls into Sacramento River near the city of Sacramento. For about six miles it has been rendered navigable for small steamers. The north fork, considered by some as the true American River, rises among the hills at the base of the Sierra Nevada, flows west-southwest, forming the boundaries between Placer and El Dorado counties for 100 miles, and unites with the south fork 30 miles above the city of Sacramento. The south fork flows from Bonpland Lake through El Dorado County, and forms part of the division between the counties of Sacramento and El Dorado.

American Scenic and Historic Preservation Society, a national organization established in 1895 for the protection of American scenery and the preservation of American landmarks.

American Shipbuilding. The inception and development of this industry in America is primarily due to the enterprise of the early colonists of New England, who thus wove into the fabric of a history of isolated colonization, replete with incidents of hardships and self-sacrifice, the magical thread of commerce which connected them with the outside world.

The first effort was inspired by the desire of the members of the Church of England Colony, established at Sagadahoc, Maine, in 1607, to return to the mother country after the discouraging experiences of a hard New England winter. Thus, at the mouth of the Kennebec River, near one of the most important shipyards of the present time, the keel of the first American-built ship was laid, a little two-masted vessel about 60 feet long, which was named the "Virginia." From that time up to 1630, a few small vessels were built for various special purposes; but, shipbuilding did not assume the dignity of an industry until the trade of Brazil and the Dutch West Indies, monopolized by the Dutch West India Company, was thrown open to the colonists of New Amsterdam. This gave an impetus that was felt all along the coast. Boston and Salem builders produced several vessels ranging in size from 150 to 300 tons, which engaged in profitable trade with Spanish ports; while the shipping owned in the port of New Amsterdam increased in less than 20 years, from a fleet of 15 or 20 small vessels, to one of 60 good-sized ships, and over 100 sloops, engaged in both foreign and coast-wise trade, and from this time up to the middle of the 18th century, the industry grew steadily under impulses from one source or another. New York (New Amsterdam) was engaged in an extensive ex-

porting trade of flour and biscuits, while Massachusetts employed at least 1,000 vessels in the development of her fishing trade. The period from 1750–70 may, therefore, be considered the first epoch of the industry. In the latter year, the American vessels represented a tonnage of about 400,000, approximately one-third that of Great Britain, and nearly one-half of this amount was turned out of the shipyards of Massachusetts. By this time, however, Philadelphia had become a big center of activity. It was the most accessible port to the West Indies, our principal market at that time, and consequently turned out a large proportion of the 400 or more vessels built annually in the country.

The beginning of the Revolution, therefore, found the industry in a most flourishing condition, and although during the following war the merchant marine and the fishing and whaling fleets of the country were practically annihilated, the demand for privateers and vessels of war served to sustain the effort until the close of hostilities allowed its redevelopment, so that at the close of the 18th century, the tonnage of American shipping amounted to nearly 700,000. From 1800 to 1812, however, the commercial hostility of Great Britain practically manifested by the exclusion of the West Indian trade from the Americans, the seizure and confiscation of their ships, and the detention of a large number of them in various ports, for alleged evasions of British laws, prevented the much greater development probable under different conditions.

The War of 1812 gave the finishing stroke and caused a sharp decline in the industry until 1815, when a new impulse was given by a rapidly increasing coast-wise trade, and the demand for a larger number of packets in the line of transatlantic passenger transportation, due to the increased emigration from Europe to America at the close of the war. The annual tonnage increased steadily from about 50,000 in 1820, to about 600,000 in 1855. Several packet lines were established between New York, Philadelphia, and Boston and British and French and other European ports, and also a great many lines touching at the important ports along the coast from Portland, Maine, to New Orleans, La., and the gulf ports of South America and Mexico. The vessels were built on speedy lines; had roomy accommodations for passengers; ranged in size from 500 to 1,000 tons, and marked one of the most prosperous periods of the industry. About the year 1840, English steamers were placed in competition with those sailing packets, and aided by their superior carrying capacity, slowly but surely supplanted them in the course of a few years.

The vessels thus thrown out of the packet line service were converted into freighters, and caused a slight decline in the industry, which, however, was relieved about the year 1835 by the demand for large and swift-sailing vessels for the Chinese tea trade. This inaugurated the era of famous clipper ships, the construction of which being still further stimulated by the Californian gold discoveries of '49, extended the period of their maximum usefulness to the beginning of the Civil War in 1860.

These vessels represented the highest skill of the American naval architect. The shipyards of New York, Boston, and Philadelphia built them in sizes ranging from 750 to 2,400 tons.

Their lines were laid down sharp, and under their lofty masts and enormous spreads of canvas, they made the best records ever made by sailing vessels, and the tonnage of American shipping very nearly equalled that of Great Britain.

The Civil War, however, terminated their career. English-built Confederate privateers, running under steam, swept the seas, and American ships representing hundred of thousands of tonnage were either destroyed or were compelled to seek protection under foreign flags.

At the end of that war, America was no longer a maritime nation. The events of that war had developed new principles and new methods of shipbuilding. The advantages to be derived from the use of iron as a material of construction had been demonstrated beyond a doubt sometime previously, and while the industries of America were paralyzed by the internecine conflict, the English shipyards had taken full advantage of their opportunity, and backed by governmental subsidies, had re-established Great Britain's old-time supremacy of the sea.

From 1860 to 1882, the stagnation in the American effort was extreme. In 1855 the number of vessels turned out of the American yards amounted to 381 ships and barks, and 126 brigs, while in 1885 only 11 ships and barks left the ways.

The seriousness of the situation was recognized by the American capitalists as early as 1870. It was plain that a great producing nation could not be truly great, or develop itself to an extent commensurate with its vast natural resources, without the possession of an ample merchant marine, and they decided to revive the shipbuilding industry. Accordingly, 4 steamers, the Ohio, Indiana, Pennsylvania, and Illinois, were built by the Cramp Company, of Philadelphia, for the transatlantic trade. They were unquestionably as fine as any vessels of their time, but they were unable to compete with the British vessels which operated under larger subsidies.

It was apparent that adequate governmental subsidies were necessary to sustain the effort of private capitalists, and that the growth of the British merchant marine was directly due to such liberal assistance.

Therefore, steps were taken by the various steamship companies, to obtain large concessions from the government, and the Pacific Mail Steamship Company, which was already receiving a subsidy of $500,000 per annum, for a monthly mail service to Japan and China, offered to double the service for an additional $500,000 per annum. A bill granting this subsidy was passed by Congress in 1873, but disclosures confirming the fact that a million dollars had been spent by the company to influence a favorable vote in Congress, and the subsequent failure of the company to comply with the requirements of the bill, led to the abrogation of the new contract by the government. The total subsidies paid to the Pacific Mail Company during its 10 years of contract service amounted to $4,583,000; but, as no increase in the Oriental trade of the United States could be traced directly to the influence of a subsidized mail service, the resultant effect was a steady decline of the merchant marine.

Another attempt to ameliorate these conditions and affect a revival was made when the steamships New York and Paris, of the Inter-

THE "MASSACHUSETTS."

ONE OF THE LARGEST CARGO CARRIERS EVER BUILT FOR THE ATLANTIC TRADE IN AMERICAN SHIPYARDS.

THE MINNESOTA, THE LARGEST VESSEL BUILT IN AMERICA

Length, 630 feet; Breadth, 73 feet 6 inches; Molded Depth, 56 feet; Displacement on 33 feet draft, 33,000 tons; Speed, 14 knots.

national Navigation Company's line, were admitted to an American register on the condition that two other vessels, their equal in every particular, should be built in American ship yards. The government granted to these vessels a payment of $4 a mile for carrying the mails upon the condition that they were capable of maintaining a sustained speed of 20 knots an hour.

The result of this agreement was the construction of the steamships St. Louis and St. Paul in 1895, and the effective application of the system of mail-carrying contracts.

At the present time the subsidies for carrying the mails are defined on a mileage basis. It amounts to $4 per mile for first class steamers; $2 a mile for second class steamers; $1 a mile for third class steamers; and 66 2/3 cents per mile for fourth class steamers. In addition to this the post-office department pays American mail steamships $1.60 a pound for first class matter, and 8 cents a pound for all matter below that grade.

The first general subsidy measure designed to establish a system of direct navigation bounties was introduced in the United States Senate in 1898, and was passed by that legislative body in March, 1902. It consisted of four titles: "Ocean mail steamers," "general subsidy," "deep-sea fisheries," and "general provisions." Payments for carrying mails were based upon speed and tonnage instead of mileage, and the ocean mail steamers were divided into seven classes on this basis. For 100 miles sailed, steamers of the first class received 2.7 cents per gross ton; those of the second class, 2.5 cents; third class, 2.3 cents; fourth class, 2.1 cents; fifth class, 1.9 cents; sixth class, 1.7 cents; and those of the seventh class, 1.5 cents. The section entitled "general subsidy," provided for the payment of a bounty of 1 cent per gross ton for every 100 nautical miles sailed, to all vessels not receiving the mail subsidy, and was intended to offset the alleged greater cost of construction, and the greater expenses incurred in the navigation of American vessels. Under the title "deep-sea fisheries," provision was made to grant a bounty of $2 per gross ton per annum on American vessels engaged for at least three months in deep-sea fishing, and $1 per month to each sailor employed on such vessels. This measure was brought before the House during the last session of the Fifty-seventh Congress; but was adversely reported upon by the committee in charge and failed to become a law.

The period of great internal development of the country is practically at an end. The great railroad systems are practically built, and the vast accumulations of wealth in the country are seeking investment. If it is demonstrable that the margin of profits on present investments can be enhanced or even prevented from declining by investments in ships, such investments will be made and the industry will grow steadily but surely under the normal conditions of trade.

In this connection it is interesting to note the evolution of that distinctly American type of vessel, the "schooner." From a handy two-masted craft of about 100 or 150 tons, extremely serviceable in the coast-wise trade, it has been developed to the mammoth "seven master" of the Thomas W. Lawson type. The development of the larger schooners appears to have been along the lines of maximum carrying capacity at the minimum operative expense. Yet, since the building of the Thomas W. Lawson, in 1902, no effort has been made to duplicate her, although she has made several fast trips from Chesapeake Bay to Boston, and they were undoubtedly remunerative.

In fact only one six-masted schooner is under construction at the present time (1905), and no seven-masted schooner is even under contemplation.

The reasons for this are quite clear. Her extreme length of 395 feet makes her unavailable for the general coasting trade, as she is unable to load for crooked river ports, and is a misfit at many of the wharves at other places.

It is, therefore, apparent that in the matter of size the sailing vessel has reached her limit, and is already showing a tendency to go back to the less unwieldy five-master, well adapted, not only to the coast-wise trade, but also to the trade with foreign countries, involving extended deep-sea voyages.

For detailed information relative to the development of the American shipbuilding industry during the last decade in special lines, consult the articles under the titles NAVAL CONSTRUCTION; SAILING VESSELS; SHIP; SHIPBUILDING; and STEAM VESSELS, in this encyclopædia.

American Silkworm. See SILKWORM.

American Social Science Association. See SOCIAL SCIENCE ASSOCIATION, AMERICAN.

American Society of Civil Engineers, an association organized 5 Nov. 1852, in the City of New York, its object being the professional improvement of its members, the encouragement of social intercourse among men of practical science, the advancement of engineering in its several branches, and of architecture, and the establishment of a central point of reference and union for its members. Among the means to be employed for attaining these ends are periodical meetings for the reading of professional papers, and the discussion of scientific subjects, the foundation of a library, the collection of maps, drawings and models, and the publication of such parts of the proceedings as may be deemed expedient.

The early life of the Society was a struggle for existence and it was not until 1867 that the organization had a permanent headquarters, and began its work in earnest. The first publication was the address of President James P. Kirkwood, delivered 4 Dec. 1867, and printed in Vol. I. of 'Transactions' bearing date of 1872. The first Annual Convention was held in New York 16 June 1869, 55 members being present. The second and third conventions were also held in New York, but the fourth was held in Chicago and the annual conventions are now held at widely separated points. In 1869 the membership of the Society was 160; the membership in 1904 is over 3,200. The society has a splendid library of over 50,000 volumes, thoroughly classified and indexed and which is kept up to date by new additions. A monthly publication of 'Proceedings' is issued in which are printed the professional papers in advance of their presentation at the semi-monthly meetings. These papers with all the discussion to which they give rise, are subsequently printed in 'Transactions,' two and sometimes three volumes of which are issued an-

nually. The last report of the Secretary shows the assets of the Society to be over $235,000.

The organization is in no sense a local one, and it has never had any subsidiary branches or been affiliated with other organizations. Its membership is made up of practitioners engaged in all branches of Civil Engineering, the broadest interpretation of that term being used. From the beginning, admission to its privileges has been dependent solely upon professional experience and personal character.

That the Society is beneficial to the profession is evidenced by the eagerness with which membership in it is sought. The reasons for this are apparent, inasmuch as among its objects are to assist the young engineer professionally during the earlier years of his career, and, when he has proved himself worthy, to stamp him as one qualified to direct "the great sources of Power in Nature for the use and convenience of Man."

That its influence is far-reaching is shown by the fact that it has members in 51 of the 54 subdivisions of the United States, as well as in 31 foreign countries. This foreign membership constitutes 9½ per cent of the total list.

CHARLES WARREN HUNT,
Secretary of the Society.

American Society of Mechanical Engineers, a professional organization composed of engineers practising principally in the department of generation, distribution and utilization of mechanical power. It is one of four organizations of engineers, national in its character and with a considerable foreign membership also, which exists for the purpose of the reading and discussion and publication of papers on engineering subjects and for the advancement of the profession of engineering in any direction within its scope.

The society was formed in 1880 by a group of persons in and near New York city, who recognized that the existing societies of mining and civil engineers did not naturally and instinctively offer a scope for the developing strength of mechanical engineering in the United States. Its first meeting was held in New York city in the autumn of 1880. Since that two meetings have been held each year; the annual meeting in the city of New York, and the other meeting in various cities of the Union; meetings have fallen in Boston, Providence, Philadelphia, Altoona, Pittsburg, Cleveland, Nashville, Richmond, St. Louis, Chicago, and San Francisco.

These meetings last three or four days and are always made the occasion of visits to important engineering enterprises in the city which is entertaining the society. Usually from 15 to 20 papers are read and discussed at each of these meetings and the papers with their discussions are issued to all members in the form of an annual volume, averaging a thousand pages and copiously illustrated. These volumes which are designated 'Transactions' are an accumulation of most valuable professional literature, results of tests and experiments, researches into new fields and are filled with recorded data of observation.

The society was incorporated as a national organization under the laws of New York State in 1881, and has maintained its executive offices in New York city. For seven or eight years its headquarters were in office buildings in the business district, but in 1889 the movement was started of having its library of professional literature open in the evenings and for this purpose the society rented quarters in the Mott Memorial Library building, Madison Avenue near 27th Street. The success of the evening opening of its library warranted the step which was taken in 1890 of purchasing the property which had been altered by the New York Academy of Medicine for this purpose and which included not only a library space and equipment, but a convenient auditorium of small size for the holding of meetings. The society expects to be a participant in the provision of a wealthy engineer and donor whereby three of these national societies will be accommodated in a special building designed specifically for the needs of organizations of this class.

In addition to the publication of an annual volume the society conducts a free public reference library of engineering. This library is particularly rich in the current contributions to other scientific and engineering societies both in English and in other languages and in periodical literature published through the journals of technical journalism, both at home and abroad. This class of literature is of special significance in lines in which progress is as rapid as in the industrial departments of engineering. The library contains (1904) over 9,000 books and 3,000 pamphlets. It has also a valuable collection by bequest of antiquities in engineering and scientific matters, and obtains by exchange the scientific publications of the United States Government and corresponds with the important technical societies of Europe and the continent. The cosy auditorium and the library exhibit much material in portraits, busts, and memorials of engineering achievement. It is specially rich in drawings and other documents belonging to the work and history of Robert Fulton and early steam navigation.

The society has also discharged a valuable function by the service of professional committees on special subjects. These professional committees have mainly been concerned with the work of formulating the best procedure in various lines, with a view of having such procedure a species of standard whereby uniformity might be secured. Committees of the society have reported on uniform methods for conducting tests of boilers, on uniform methods of conducting tests of engines; on uniform standards in structural material, and have prosecuted research on the fire resisting properties of material, advisable methods for conducting tests of strength and similar problems.

These reports are made by the best experts connected with the society, and while the society officially never adopts their recommendation by legislative action, these recommendations carry great weight by reason of the sources from which they come.

The society is governed by a council, consisting of a president, six vice-presidents, nine managers, a secretary and a treasurer.

F. R. HUTTON,
Secretary of the Society.

American Society of Naval Engineers, organized 1888 for the purpose of publishing a quarterly journal covering the general field of

marine engineering and naval architecture with cognate subjects bearing on these. The publications of this society are regarded as works of reference by the marine-engine builders of the world, as well as by the admiralty officials of the various countries. During the existence of the society special effort has been made to cover every distinct feature of marine engineering design. While the council of the society has been exceedingly conservative as regards admitting original material to the columns of the 'Journal' of the society, special encouragement has been given to naval officers to take up original work, and to particularly note the engineering weaknesses of warship construction, so that each new type of war vessel, at least as far as machinery design is concerned, will be a distinct improvement upon its predecessor. Subscribers to the 'Journal' are members. Office of secretary, Washington, D. C.

American Street Railways. As far back as 1630 an enterprising mine owner at Newcastle-on-Tyne, finding the roads between his mines and the river so bad as to seriously interfere with the hauling of coal, conceived the idea of laying in the road wooden rails, and running thereon cars with wooden wheels. From that time to the present the transportation of goods and passengers has been a leading industry. The idea of the street railway grew out of the steam railroad agitation, when the first steam railroad was built in the United States in 1829. This idea rapidly materialized and the first street railway was built in New York City in 1832, the tracks being laid on Fourth Avenue from Prince Street to Harlem, the rail consisting of strips of flat-iron laid on granite blocks. The cars resembled the stage coach then in use and were mounted on flanged wheels. This road being a financial failure, it was not until 1836 that the next street railway was built in Boston. After this time street railways were built in all large American cities, and between 1860 and 1880 the horse railway had become an established institution. As cities grew and distances became longer, there was created a need of a motive power to draw the cars faster than horses could transport them. In some cases steam locomotives were used in the suburbs of large cities, but this was considered impracticable on account of the noise, dirt, and danger.

Numerous systems of propulsion were proposed and large expenditures were made in tests and trials. The first practicable method found was that of drawing the cars by an endless wire cable, and this method was first used in San Francisco in 1873 with much satisfaction where it was well suited for roads with heavy traffic and steep grades. This system was used in nearly all the large cities during the next 10 years. It was soon conceded, however, that the cable system was not the ideal one for moving cars as there were certain mechanical difficulties in its operation which were extremely burdensome, and experiments were continued with other systems between 1880 and 1890, resulting in the use of electric motors. The names of Edison and Thompson are identified with this work. The first street railway to be entirely equipped with electric cars and successfully and continuously operated, was a road 12 miles long, in Richmond, Va., built in 1888. As soon as this road demonstrated that the electric motor could pull street cars reliably and economically, horse roads all over the United States were changed to electric roads, and many new roads and extensions were built into the suburbs of the great cities.

The electric railway, a distinctly American institution, has now spread all over the world. In the United States there are more than 25,000 miles of electric railway track, covering an investment of more than $2,200,000,000, employing more than 150,000 persons and daily transporting about 15,000,000 people. Besides the transportation of passengers, express and freight cars, mail cars, parlor cars, and even funeral cars, are familiar sights on the street railways of American cities. Interurban electric railways have been built in the outskirts of the large cities, and between towns, on a large scale, and there are now very few towns of more than 5,000 inhabitants which are not connected with their neighbors by means of an electric railway.

Many problems in electricity have been developed in keeping pace with the street railway, the latest of which is the alternating current. It is readily seen that an alternating current system of electric traction which would permit the use of a high transmission line potential and avoid the transformation to direct current by means of the rotary converter, would give an impetus to the electrical solution of transportation problems greater even than that which followed the introduction of the rotary converter. That the direct current, because of its limitation as to voltage, is inadequate as a system for the distributing of power over a wide area, is now firmly established. The alternating current system, permitting a change of potential by means of the simple and efficient static transformer, has already successfully met the requirements of transmission and distribution of electric power. The necessity of using direct current for the operation of cars has, however, greatly restricted its application to general railway service, involving, as it does, the introduction of the rotary converter with its auxiliary apparatus, increasing the cost both of installation and operation and reducing the commercial efficiency of the system as a whole.

Catenary line construction is intended for high tension trolley roads, operated at potentials up to 6,000 volts or more. It is especially designed for use in conjunction with single phase alternating current railway equipment, and marks one step further in the movement to secure a greater degree of economy and efficiency in the operation of electric trolley lines. The employment of high tension currents for traction purposes necessitates the use of an improved trolley equipment, possessing an efficiency and a reliability of a high order. The speed attained upon interurban lines makes it difficult to obtain satisfactory service with a trolley wire which dips between supports and sags and sways with every impulse. Increased precautions against accidents and faulty construction are also necessary because of the increased liability of damage from any diversion of the line current from its proper channel.

In late years there has been a rapidly increasing demand for a controlling system applicable to trains of motor cars as well as to cars operated singly. This demand has been met by the development of the unit switch system of multiple control, which consists of a skillful

combination of electro-magnetic and pneumatic devices, each applied to those operations in which experience has shown it to be most effective. The construction is noticeable for the liberal design of its working parts and contacts, and the great margin of power available for their operation; while the general design and simplicity of operation insures great reliability of service and low cost of maintenance. See STREET RAILWAYS.

EDWARD S. FARROW,
Consulting Railroad and Mining Engineer.

American Sunday-school Union, a religious association having for its object the organization and support of Sunday-schools in needy neighborhoods, or those where religious sentiment is too divided to sustain denominational ones; the publication of religious juvenile literature, etc. It is not a union of churches, but of Christians of various denominations, requiring no common creed but a desire to save souls and promote the study of the Bible; and is managed entirely by laymen, though employing both ministers and laymen as officials and in its work, which of course includes the maintenance of missionaries to organize schools and enliven religious sentiment. It has had but six presidents in nearly 80 years of work,— Alexander Henry, John McLean, John A. Brown, Robert L. Kennedy, William Strong, and the present president, Morris K. Jesup. It has also a board of managers, the members elected for one, two, and three years; and an executive committee. Its headquarters are at Philadelphia, where it first came into being. Its germ was the First-Day Society, founded in 1791, whose managers petitioned for free schools in Pennsylvania; this led to the formation of the Philadelphia Sunday and Adult School Union in 1817, which later united with similar societies and changed its name to the present title in 1824. In 1821 the Philadelphia union published one book and supported one missionary; in 1902 it maintained nearly 100 permanent missionaries and published several thousand books and other publications. Its income is about $125,000 a year, and it organizes on an average about 1,350 Sunday-schools annually.

American University, The. Prof. Ladd of Yale University, in an essay originally read before the "Round Table" of Boston, about 1888, says: "Any one possessed of the requisite information knows at once what is meant by the university of France, the English universities, or a German university; but no one can become so conversant with facts as to tell what an American university is." And again: "— it is scarcely less true than it was a score of years ago, that, although there may be universities in America, no one can tell what an *American* university is."

While not so accurate at the present day as when first made, it is still true enough, if one fail to free himself at the very start from dependence upon the name as necessarily indicative of the thing. It is incontestable that within recent years the conception of the natural and necessary relation of the "university" to the "college" has become much clearer, and that many and important changes of organization and administration have resulted, so that it is certainly easier than it was in 1888 to define, or at least to describe, the American university. However, there remain difficulties of many kinds; and it still is, and will undoubtedly be for years to come, if not actually impossible, at least very difficult, to give a definition broad enough to include all institutions of learning in the United States which possess true university character, and precise enough to exclude all others.

The first difficulty is this: The names "university" and "college," as used in the official titles of institutions, are absolutely worthless as indications of the character of these institutions. Among the scores of titular "universities" in this country most are merely colleges, some good, some indifferent, some so badly endowed and organized as to be not even good high schools. On the other hand, Bryn Mawr "college" has never assumed, even in informal use, the name "university," yet offers true university instruction of the highest order in most of the subjects covered by the *philosophische Fakultät* of a German university; and even Harvard and Columbia, though they have now acquired a true university character, of a very elaborate type, and are habitually spoken of as such, have retained in their corporate titles their ancient designation of "college." It happens that in the most eastern States the word "university" is much less used as a title, the higher institutions of learning having mostly been founded while the English influence was still strong, many of them indeed in colonial times, under direct English authority, and so having adopted the peculiarly English name of "college." In the newer States more ambitious plans prevailed, and the consideration of conditions in non-English European countries — notably those of Germany, where the universities had obtained a more commanding position and influence than elsewhere by the beginning of the 19th century — led to the choice of the name of apparently greater dignity. This consideration seems also to have been paramount with the founders of the countless purely sectarian institutions which sprang up all over the country, and still lead a precarious existence, striving to hold the attention of their brethren in the faith by promiscuously showering down honorary degrees. Yet it would be grossly unfair to assume that in all cases the name of university was adopted out of pure conceit; in many the choice of name was the proclamation of a purpose sincerely cherished, and resolutely carried forward, amid difficulties of which the European critic can form no conception, to a realization more or less complete. It will be necessary then to get rid of this first difficulty by ignoring completely tne difference in title. If we shall succeed in describing the thing, though we may be ever conscious of the un-

fortunate ambiguity of terms, now doubtless too firmly fixed in official and legal use to be easily changed, we may rest content.

Another difficulty is this. It is now clearly seen that, as institutions, the college and the university, having very different functions, demand a different organization and administration. Yet the full recognition of this fact is comparatively recent, and the logical consequences have been reached in only a few instances. The circumstances of foundation and the necessities of the hour have made it practically impossible for the university and the college in the United States to exist apart. There are still but two institutions which may be called even fragmentary universities entirely unconnected with a college: The Clark University of Worcester, Mass., and the Catholic University of America at Washington. Down to 1876, when the Johns Hopkins University was opened, whatever real university instruction was offered was organized at a college already existing, and even the founders of the Johns Hopkins, though their chief purpose was avowedly to provide for university instruction of the highest grade, felt it necessary or at least advisable to organize a college also. The wide scope planned for Cornell University, opened in 1868, from the first necessarily included a college, nay, many colleges, as part of the scheme. In all discussion of the American university, therefore, in this article it must be borne in mind that the term (with the two exceptions noted above) is used to include only certain parts of institutions whose organism is often highly complex, and that probably no two institutions coincide in theory or even in practice, though certain principles and practices are common to those of more complete type.

What then is that American university, a description of which is here undertaken, if it does not anywhere exist in completeness and exactness, unobscured by contact with institutions of different character and divergent aims? It will be least misleading to say at the outset: It is nowhere. In so far, therefore, Prof. von Holst's famous pronouncement is right: a university in the European sense does not exist in America. And yet, from Harvard on the Atlantic tidewater to the University of California, which looks out through the Golden Gate upon the Pacific, and from Minneapolis to New Orleans, will be found many institutions which offer training in the methods of scientific research, opportunities for the prosecution of such research, and abundant facilities in the way of libraries, museums and laboratories, to those individuals who have had such preliminary training as to be able to profit fully by these advantages, and which certify by the formal bestowal of a particular degree or degrees that the individual receiving one of them has proved himself or herself to have acquired the methods and habits of such scientific research. This is equivalent to saying, in the technical language in vogue in the United States, that these institutions offer to graduate students courses leading to advanced or higher degrees. Where such courses are well organized and equipped and successfully maintained, there is a university at least in part, and, it may be, in the whole. Whether the institution do only this, or this and many other things besides, and whether it be called university or college, may be important questions from some points of view; for the point of view of this discussion the existence of such organization for research work by graduates is the test, and it is its purpose to describe as clearly as possible such organization of this character as may be found in the United States of America. Apparent or evident divagations from this strict purpose will perhaps find readier pardon from the foregoing allusions to some of the difficulties in the way.

It has often been remarked by observant foreign travelers in the United States that among this young people many institutions change less rapidly than in the older nations of Europe. This conservatism, in large part an English trait persisting through many generations, is particularly observable in the field of education; experiments are carefully tried, downright innovations still less willingly adopted. Only where occasion is offered for new foundations are we apt to find a ready breaking with traditional forms. When, on reviewing the American institutions of learning to discover which of them give the opportunities for training in the methods of research that we have taken as our standard of measurement, we find them to be almost without exception colleges, or technical schools, or professional schools as well, or all of these together, we also find that they were generally colleges first of all, and that training in research was made a part of the system only later, very gradually and hesitatingly, the two institutions which disclaim all "college" work being almost the youngest, and one of them not yet displaying a very encouraging vitality. We find also that one of the oldest and most famous colleges of all, Yale, was also the first to institute regular courses of instruction for those who wished to pursue their studies after receiving the degree of bachelor of arts.

The union of college and university may fairly be called the typical American form of organization for the higher education. Only in the institutions of comparatively recent origin do we find that university organization was attempted from the first. The professional and technical schools have generally occupied a position of great independence toward the institution as a whole, in many cases having hardly more than the name in common, but possessing their own budgets and boards of trustees, sometimes even being administered as proprietary schools, wherein the professors divided among themselves the fees paid by the students. The medical schools have been the most independent in this respect. It should be borne in mind that in the case of such complex institutions the name "university" is applied to the whole, so that, theoretically at least, the university may include the equivalent of a German university, *technische Hochschule* (formerly called *Polytechnicum*), *landwirtschaftliche Hochschule* or agricultural college, and *Gymnasium*. Passing under review the many types of organization wherein university and college are united, we find that in most cases the graduate and undergraduate work are carried on by the same individuals, so that, instead of a university and a college being in alliance, so to speak, as might be said if the body of instructors of each

part were composed of quite different individuals, with one governing body for the whole, we have to do really with a complex and overlapping structure. Herein lies, it must be said, one of the greatest disadvantages for the American university, though there are valuable compensations. The American university professor is rarely able to devote himself exclusively to advanced scientific work with well-prepared students, but must, in most cases, carry on a good deal of mere class work as well, which cannot but prove detrimental to the progress of his researches.

The State Universities.— At the present time, in each of 29 of the States of the Union, there is maintained a single "State university," supported exclusively or prevailingly from public funds, and managed under the more or less direct control of the legislature and administrative officers of the State. In some cases private benefactions have notably supplemented the support given from public revenues. These States are the following: Alabama, California, Colorado, Georgia, Illinois, Indiana, Iowa, Kansas, Louisiana, Maine, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, North Carolina, North Dakota, Ohio, Oregon, South Carolina, South Dakota, Tennessee, Texas, Virginia, Washington, West Virginia, Wisconsin, Wyoming.* The organization of these institutions, while more similar than that of the universities which are autonomous corporations, yet shows many points of divergence; and their extent and standards of scholarship vary even more widely. The larger among them exhibit a very complete development of technical and professional schools, with the exception of schools of theology, which naturally have no place in a country where State aid is not extended to religion. The professional schools of law and medicine, however, are generally supported, at least in greater part, by the fees received from students, and up to the present time none of them has been put on a true university basis. Otherwise, the sources of income of these universities are mainly the following: (1) The proceeds of land-grants made in 1862 by the Federal government, in accordance with the famous "Morrill Act" of 1862, for the maintenances of colleges whose leading object should be instruction in those branches of learning relating to agricultural and mechanical arts, including military tactics, and not excluding other scientific and classical studies. (2) State taxation, whether by way of annual appropriations from the general taxes of the state, or by continuous appropriations from a permanent special tax. (3) Tuition fees (only in some of the universities, while in many instruction is entirely gratuitous). (4) Private gifts and endowments — the least common source of revenue, although some brilliant exceptions are to be noted.

The universal verdict of public opinion, in the States where such institutions are maintained, is that they, as State organizations supported directly by public taxation from which no taxable individual is exempt, should be open without distinction of sex, color or religion to all who can profit by the instruction therein given. Each forms the uppermost division of the general system of public education of the State in which it is maintained, and is managed with a view to completing the scheme of instruction begun in the primary and carried on in the secondary schools. Control is vested in a board of public officials, generally called "regents." For example, the board of regents of the University of Minnesota consists of the governor of the State, the superintendent of public instruction, the president of the university, and seven members appointed by the governor and confirmed by the senate. In Michigan the regents are elected by popular vote for terms of eight years — an unusual feature. The composition and mode of choice of these boards varies greatly in different States, and not less their fitness for the responsibilities entrusted to them. In some States, as in Michigan and Wisconsin, the result of many years' endeavor has been, though after many vicissitudes and bitter struggles, the creation of noble schools of training; in others the constant changes in political complexion of the legislature, and the self-seeking of party leaders, have made the universities mere shuttlecocks of public or party opinion, and not only has their development been hindered, but in some cases their usefulness deliberately crippled. Instances are not unknown where particularly able and courageous professors, who would not cut their scientific opinions after the prevailing fashion in politics, have been driven from their chairs, even by outrageously underhanded methods. Of the State universities the most prominent and successful are those of Michigan, Minnesota, Wisconsin, and California. The first mentioned is the oldest and perhaps the best known. Under the direction of a series of singularly able men it has grown, since its foundation in 1837, into a position of commanding importance. The three others, while considerably younger, have shown a surprisingly rapid growth. See STATE UNIVERSITIES.

Contrast with European Universities.—The foregoing account of the chief types of university organization in the United States will, it is hoped, have made clear most of the details in which their structure is peculiarly American. The older institutions, starting from the English type of college, never developed in the direction of universities of Oxford and Cambridge, where the idea of the university as a great teaching body was lost in the excessive development of the college as a place of residence, and of the university as primarily a congeries of colleges. The early mediæval universities of Europe, on the continent as well as in England, generally provided for their students places of residence in buildings set apart for this purpose, instruction of the lower grades in connection with these residence halls, and higher instruction independently of them. On the continent, however, especially in France and Germany, the residential feature rapidly became less important, and finally, with a few unimportant exceptions, disappeared altogether, so that the entire resources of the universities, though often scanty enough, could be turned to account for the work of instruction. In England exactly the opposite occurred; the residential halls became, through the impulse of successive pious foundations, the important factors in the university life, even attaining corporate independ-

* The University of the State of New York is not a university at all, but rather a State board of education, with supervision of all instruction given in the State. The "University of France," as constituted under Napoleon I., is closely analogous to it.

ence and ultimately great wealth, and gradually assumed most of the instruction of the students, though the examinations and the award of degrees remained the prerogatives of the university as a whole — conditions which made directly for the fixity of residence characteristic of English universities, and adopted as a matter of course in the American colleges patterned after the English model. If the establishment of Harvard and Yale colleges had been followed at brief intervals of time by the foundation of other residential colleges in Cambridge and New Haven, and if there had existed in the colonies an established church with a prestige such as that possessed by the Church of England in the home country, keeping the colleges under its control, a state of affairs similar to that at Oxford would doubtless have resulted. The scanty population and limited means of the colonies, and their independence of the Church of England, prevented such a result, fortunately, on the whole, for the educational welfare of the country at large. Yet the residential feature has persisted throughout the history of the American college; though abandoned here and there, as at Columbia and the University of Pennsylvania, it has been restored at the latter, has again been adopted in principle, if not yet in practice, at Columbia, and deliberately introduced, in various forms, at many new institutions, even in some which at first had made no provision for students' residence. The American institutions differ furthermore from the English universities in this, that their growth has been so largely in the direction of professional and technical schools, though these have been thus far in less than a half a dozen instances placed on a real university basis.

The points of difference between the American and the continental European universities are not less apparent. Taken as a whole, the American institutions exhibit only a portion of what in Europe is thought necessary to the constitution of a complete university, viz., the traditional four faculties of theology, law, medicine and philosophy, because, although all four may be in existence (as for example at Harvard), they are not all organized and administered on the same plane; but on the other hand they include elements which in Europe are sharply marked off from the universities, namely, technical schools, and undergraduate schools, which in some cases correspond fairly well to the lycée or gymnasium of France or Germany, in others to the last two or three years of these institutions and the first year of the university or technical school. If we separate the strictly graduate schools of the American universities from the remainder of their respective institutions, we shall find them in general covering pretty nearly the ground of the "philosophical faculties" of Germany, and more or less closely approximating them in methods of work. A decided point of difference, however, consists in the comparative infrequence of migration on the part of students from university to university, which is so nearly the universal rule in Germany.

Present Day Problems.— When the problems of education are all solved, education itself will be dead, and the need of it greater than ever. The entire range of education in the United States has been in a state of rapid transition for many years already, and nowhere have the changes been more constant than in the domain of college and university education. From the establishment of graduate courses at Yale in 1847 until the present day, probably no year has passed without seeing some new experiment tried, some old institution reorganized or new one founded. If the new institutions have often shown too little willingness to profit by the experience of others, or to adopt the ways and means of other lands, it must be remembered that the educational problem has been but one of many with which the leaders of thought in this country have been confronted, and that in the attempt to conform institutions to the spirit of the country it has been necessary first to discover, often at great pains and heavy cost to the experimenter, what that spirit was.

Naturally the most important question has been and still is that of organization. It has doubtless become apparent from the foregoing description that no two universities are just alike, and that the differences do not by any means concern unimportant points. Every possible variety of organization and administration seems to the observer — especially the foreign observer — to have been tried, except that of a consistent and rigid adherence to forms sanctioned by centuries of permanence in Europe.

The vacillation has come from uncertainty as to the true purposes of the university. In Europe these purposes were long ago settled: the university exists to train servants of the state, or, as prevailing in England, to train up a race of gentlemen who shall never forget the obligations of their caste. It is the glory of Germany that she has seen more clearly than other nations how truly the highest scientific training is none too good for her public servants.

The wholly different conditions prevailing in the United States have been reflected in the organization of our universities and colleges. There is no state religion, and the national Constitution forbids the patronage or proscription of any sect; consequently the theological faculty, originally the most important in the universities of western and northern Europe, found no state recognition. The practice of the law was subject to few restrictions, and indeed in at least one State is still open to every citizen of mature age, so that the schools of law, when they began at all, grew up mostly on a basis of private organization, with purely practical training as their object, and often underbid one another in their eagerness for students. With such exceptions as the nature of the profession brings with it, the regulation of the study and practice of medicine went the same course, proprietary schools being the most frequent form of organization for instruction in the healing art. As for the faculty of arts or philosophy, which, originally preparatory for one of the others, had in Germany been put on a par with them and made the doorway to the new profession of teaching in the State schools, its ground was partially covered by the curricula of the best colleges. The character of these colleges, however, resembled more nearly that of the German philosophical faculty of two centuries ago. The state systems of education did not at first include more than elementary schools, so that there was no great incentive for prescribing a college course for those persons who wished to teach in them; nor would such a regulation have been popular in intensely

democratic communities, or, in the poverty of many of the states, easily possible of fulfilment. Under these circumstances the European conception of a university was lost; and when it began to be regained, different systems, imperfect and incongruous it is true, but still in many ways useful, had grown up to fill the needs which are supplied in Europe by the university. Other needs had made themselves felt in America even more keenly: the needs incident to the rapid settling and exploitation of a new country, where vast distances and a phenomenal growth of population made imperative some provision for training in the technical professions and mechanical arts. It is not strange, then, though it has been unfortunate for the country at large, that the last need to be recognized in education has been the need of thorough training in the humanities and in pure science, in what has been admirably well called "disinterested scientific thinking, as distinguished from technical or commercial science."

American educators are not yet at one as regards the true function of the university. In general, two opposing views are chiefly held. The purpose of the Leland Stanford, Jr., University is declared to be: "To fit young persons for success in life." An admirable purpose, no doubt, but one which the university must share in common with many other institutions. Of a like breadth of conception is the avowed purpose of Ezra Cornell: "I would found an institution where any person may find instruction in any study." The brilliant history of Cornell University is chiefly due to the wisdom of the men who have seen what limitations should be put upon this great plan. This view of the true function of a university is chiefly prevalent in the West; one sometimes hears it said that the western universities exist solely for the sake of the students, while some of the eastern universities seem to think that the students exist chiefly for the sake of the universities or of science at large. The universities of private foundation are proceeding more and more on the assumption that their function is to train, in their graduate departments or faculties of philosophy, specialists, as teachers, and to a less extent as investigators; those which have raised some of their professional schools to true university rank by refusing admission to all who have not received a non-professional degree aim not merely to instruct the future physicians and lawyers in the technique of their professions, but to give them true scientific insight and philosophic grasp. Until there is agreement as to the true function of a university, there cannot be agreement as to their organization and administration. Whoever holds to the Stanford idea will wish to see all departments of instruction put on precisely the same plane; whoever believes that scientific research is the highest and noblest aim of education will demand for the university an organization which shall emphasize this, leaving to other institutions the teaching which is entirely practical.

As a whole, American universities seem to be trying to do too many things at once, generally with an altogether inadequate equipment of instructors, and with an insufficient endowment Each university aims to cover the entire field of instruction; the result is that the professors, who are, except in the professional faculties, almost always college instructors as well, are cruelly overburdened with teaching and administrative duties, with the inevitable result that few of them can carry on much research. The organization of most of our universities is too complicated. Many professors have to attend two, three, or even four faculty meetings each month, and serve on committees without number; some of them are even expected to do purely clerical work.

Perhaps the most important of American university problems at present, as bearing directly upon the necessary organization and determining it, is the relation of university or graduate work to undergraduate work and to professional training. With the very liberal regulation, often lack of regulation, exercised by the State governments over the practice of the professions of law and medicine, the number of practitioners has inevitably become excessively great. The need of stricter control has been seen, and many States have increased the requirements for admission to practice. That any of the States will require a complete collegiate education as a preliminary to admission to practice is a very remote possibility. It rests with the universities to raise the plane of their professional schools so that only the fittest will survive. Experience has shown that raising the standard of an institution is surely followed in a few years by an increase in numbers as well as in the quality of students entering. A beginning has already been made, as indicated above, for the professional schools of law and medicine. As for the technical schools, most of them, whether connected with the universities or not, have been too ready to admit students on very slight requirements. Perhaps in time the best of these will see that a good preliminary training ought to be demanded of their students, and so put themselves also on a university level.

Enough has been said, it is hoped, to show that there is little chance of re-establishing in any American university the traditional four faculties, unaccompanied by any other departments of instruction. If means were abundant, it would perhaps be advisable to separate entirely from the universities the technical schools, except such as should be willing to demand a preliminary degree for admission and to develop more fully the theoretical and research side of their teaching. At present undue prominence is given to the technical schools in many institutions, largely because they are the best paying parts, and the tone of the whole institution, as an organization that should exist as largely for the advancement of research as for any other cause, is distinctly lowered thereby.

The graduate school, or faculty of philosophy, bears closer relations with the collegiate course than can be borne by any professional faculty. The overburdening of professors alluded to above might be remedied by the appointment, where endowments would allow, of professors exclusively for graduate work on the lines of the faculty of philosophy, who should be able to engage in extended research work with advanced students. Hitherto no institution has been in a position to do this in any large degree. Nor has it been possible to try on a really instructive scale the experiment of a university without college or technical schools. Whether such a university could properly maintain a faculty of theology, it is hard to say.

The Union Theological Seminary in New York, while under Presbyterian management, is in many respects a real university faculty, and the same may be said of some few others. The relations between Columbia and the Union Seminary have become close, with the good result that many students of the latter attend courses at Columbia under the faculties of political science and philosophy, and are eligible for Columbia degrees.

Concerning the precise relation to be borne by the graduate work to that of the college, no general agreement has yet been reached. Even where the two are carefully separated, no such great dissimilarity in methods exists as prevails in Germany between the gymnasium and the university. Where, as at Harvard, the lines of demarcation are partly obliterated, the change from one method to another is very gradual. Johns Hopkins aims above all at producing specialists, and even her college courses are largely shaped to this end. The results certainly justify her policy.

The preparation which the candidates for admission to the graduate schools bring with them is naturally very varied. For many kinds of advanced work, the general training given in the college is not enough; so that the student, in order not to lose much valuable time afterward, has to begin his special studies before receiving his first degree. This is encouraged by the system in vogue at Columbia, especially in the case of students looking forward to medicine or the law. A tendency to over-early specialization is showing itself in many places; the students are naturally anxious to begin the active duties of life as soon as possible, and are unwilling to postpone the acquirement of the professional degree until the 25th or 26th year of their age. A remedy for this has been sought in several directions, but none of the plans tried has been successful enough to prevail over the others. The trouble seems to lie largely in the loss of time during the earlier school years. The pupils are not taken in hand early enough, nor do they receive severe enough training. With the improvement in organization and methods which is everywhere noticeable, it ought to be possible after a few years to send young men and women to college at 16 as well prepared as they are now at 17 or 18. With this done, the college course might well be shortened to three years.

It may be asked, what of the *Lehrfreiheit* and *Lernfreiheit*, the freedom for teacher and learner, as they are claimed for the universities of Germany, in those of America? As for the first, the American university professor has little cause for complaint; whatever may have been the case 25 years ago, he may now teach what he likes nearly everywhere, though now and then the regents of a State university, or the religious body controlling a divinity school, raise noisy protest. In one respect there is yet much room for improvement: as yet no serious effort has been made to introduce one of the most valuable features of the German university system, the system of *Privatdozenten*. It is not yet possible for a young man of ability to secure the right of lecturing at a university by merely proving that he is competent to do it. The introduction of this custom has been several times attempted, but so far with quite insignificant results.

As for the *Lernfreiheit*, that too has become naturalized among us; even the undergraduate enjoys a large measure of it, largest in those colleges where the elective system has taken firm root. One development of it, the migration of students from one university to another without loss of standing, is still unsatisfactory. The custom is highly desirable, and is steadily gaining ground in America; it is much commoner from the colleges to the purely professional schools, students of law and medicine naturally seeking the large cities; the chief obstacles to its adoption are the differences between the various universities in the matter of organization and of requirements for degrees, and the close connection between college and university which lead the college graduate in many instances to remain for graduate work where he has taken his bachelor's degree, out of pure attachment to his alma mater.

It is interesting to observe how rapidly the spirit of independence with responsibility is developing among the graduate students. At 22 or more institutions which maintain graduate schools the students in these have formed themselves into associations for the furtherance of their mutual interests, and these clubs have formed a national federation which holds annual meetings, where papers are read, and questions affecting the whole range of graduate work are discussed. The interest shown in these proceedings, and the intelligent spirit in which many important questions are approached, make these associations into a most valuable adjunct to the work of the graduate schools. At the fourth annual convention, held at Cambridge, Mass., in December, 1898, addresses were delivered by President Eliot and Prof. J. W. White, of Harvard, and papers were read, followed by animated discussion, on the following topics: The migration of students; the regulations concerning major and minor subjects; specialized scholarship *v.* preparation for teaching, as a basis for graduate study; the master's degree; graduate studies in European universities; the regulation of graduate to undergraduate courses. The federation of graduate clubs also carries on a determined opposition to the practice of conferring the Ph. D. *honoris causa*.

A project vigorously advocated by many eminent American educators is the foundation of a national university for the United States, to be situated at Washington, to be controlled by a board of regents under the chairmanship of the President of the United States, and to be constituted on the true university basis of admitting to any of its schools only those who have received the preliminary training shown by the possession of a bachelor's degree. The plan is an alluring one from some points of view. (See NATIONAL UNIVERSITY.) To add another institution of learning to those that swarm in the United States, unless the new comer should at once outrank them all in the magnitude and completeness of its equipment, and unless its rise should imply the setting of a number of the minor lights, would be a very doubtful service to the cause of university education. So far no endowments at all comparable with those of half-a-dozen of the universities already existing have appeared; and it is extremely doubtful whether congress could be depended upon to give the institution the thoroughly adequate sup-

port without which it must remain at best one additional "torso of a university."

Amerind, a word suggested by Maj. J. W. Powell to describe the American Indians as distinguished from other Indians.

Amerling, ä'mėr-lĭng, **Friedrich,** Austrian painter: b. Vienna 1803; d. there 1887. He studied painting in Vienna, and also in London, Paris, and Munich, and spent some years in Italy. Upon his return to Austria he was selected to paint a portrait of the Emperor Franz I., and from that time ranked as the most prominent portrait painter of that country. His portraits number about 1,000, and are distinguished by brilliant coloring, but sometimes fail of definiteness of characterization. Consult: Bodenstein, 'Hundert Jahre Kunstgeschichte Wiens' (1888); and Frankl, 'Life' (1889).

Amersfoot, a town in Holland, in the province of Utrecht, and 12 miles northeast of the town of Utrecht. By the Eem, on which it stands, it has a navigable communication with the Zuyder Zee. It manufactures woolen goods, tobacco, glass, and silk-yarn, and carries on an extensive trade in grain. The Roman Catholic church of St. Mary, built in the 14th century, has a Gothic tower 308 feet high, considered to be one of the finest in Europe. There is a college of the Jansenists in the city, it being one of the chief centres of this sect, which does not now exist outside of Holland. The Grand Pensionary of Holland, Jan von Oldenbarneveldt, commonly called Barneveldt, was born here. Pop. (1902) 20,500.

Ames, Adelbert, American soldier and Reconstruction official: b. Rockland, Me., 31 Oct. 1835. Graduating at West Point in 1861 he was assigned to the artillery and served through the Civil War with distinction: was wounded at Bull Run and brevetted for gallantry there; took part in nearly all the battles of the Peninsular campaign, in Fredericksburg, Chancellorsville, Antietam, Gettysburg, and before Petersburg; was brevetted colonel, was brigade and division commander at times, brevetted major-general of volunteers for conduct at the capture of Fort Fisher, and major-general in the regular army for general conduct in the war. In 1866 he was made lieutenant-colonel. From 1868, when he was appointed provisional governor of Mississippi (extended the next year to the 4th military district of the States lately in insurrection), to 1876, he was in the thick of the "carpet-bag" troubles; upheld by United States troops, the negro vote, and a small section of whites, mostly recent immigrants, and bitterly fought by the mass of the white inhabitants. Mississippi was among the last of the revolted States to accept Reconstruction or the War Amendments as fixed facts. The preponderant negro population and the backwardness of much of the white made the race problem more acute there than anywhere else in the South; the elements at Ames' disposal were unfit to base even a decent civilized structure upon, and they frightfully plundered and misgoverned the State; on the other hand, according to his side, the white portion would not do its best to reduce the evils by co-operating in good faith with the administration, and simply defied all orders: and the State went into anarchy tempered by local vigilance committees. He held an election for a legislature 30 Nov. 1869, convened it 11 Jan. 1870, was elected United States Senator for the unexpired term from 4 March 1869, and in 1873 was elected governor of Mississippi and resigned his seat in the Senate — the whites regarding all these elections, under the conditions, mere military usurpation and illegality. His governorship was charged with sacrificing the civilized interests of the State to the blacks, and on 7 December there was a bloody race riot at Vicksburg, followed by others through the State. Ames sent to Washington for more troops to maintain order, the white party countered with fresh charges, a congressional investigating committee was appointed, and for two years the State had — like several Southern States through this period — a formal government perfectly powerless, and a real government consisting of the rough consensus of interest among the larger white landowners. In November 1875 these recovered control of the State by suppressing the negro vote wherever troops were not actually present. The legislature which met in January impeached Ames and all his executive officers; the State Administration was paralyzed; the national administration was sick of upholding impossible local governments; and Ames finally agreed to resign if the impeachment were withdrawn. He at once removed to New York; later to Lowell, Mass. In the Spanish-American war he was a brigadier-general of volunteers.

Ames, Charles Gordon, an American clergyman, editor, and lecturer: b. Dorchester, Mass., 3 Oct. 1828. He graduated at the Geauga Seminary, Ohio; was ordained in 1849 as a Free Baptist, but later became a Unitarian and pastor of the Church of the Disciples, Boston. He was editor of the Minnesota *Republican*, the first Republican paper in the Northwest, in 1854, and the *Christian Register* of Boston, 1877–80. He wrote 'George Eliot's Two Marriages' (1886); 'As Natural as Life' (1894); 'Poems' (1898); etc. He has preached and lectured in 20 States, and has always been deeply interested in social and philanthropic questions.

Ames, Eleanor Maria (EASTERBROOK), pseudonym "Eleanor Kirk," author: b. Warren, R. I., 7 Oct. 1831. Besides numerous contributions to newspaper and periodical literature, she has published: 'Up Broadway, a Life Story' (1870); 'H. W. Beecher as a Humorist: Selections' (1887); 'Information for Authors' (1888); 'Periodicals that Pay Contributors' (privately printed); editor 'Eleanor Kirk's Idea,' a monthly magazine.

Ames, Fisher, American orator and statesman: b. Dedham, Mass., 9 April 1758; d. there, 4 July 1808. His father died when he was six. A precocious scholar, he graduated from Harvard at 16; taught school some years to support his impoverished family, cultivating himself by wide reading and profound study of the classics and the Scriptures; studied law, and began practice in Dedham in 1781. He made a reputation as "Brutus" and "Camillus" in the Boston papers, was sent to the legislature in 1788, won laurels, and was elected to the convention to ratify the Federal Constitution. His speech there on biennial elections gave him fresh repute as one of our foremost orators. In December he was elected (Federalist) Representative to Congress, and re-elected through Washington's administration to 1797: he was chosen to pronounce the congressional address to Washington on his retirement; and on 28 April 1796 delivered his masterpiece of eloquence and effectiveness, on the appropriation to carry Jay's treaty of 1794 into effect,— so impressive that the other party protested against taking a vote until after an adjournment, because the House was too excited to decide rationally. Retiring from public life on account of feeble health, he spent his later years mainly on his Dedham farm, though writing papers in 1798 to urge the Federalists to resist French aggressions, which was pouring oil on a conflagration (see ADAMS, JOHN; ALIEN AND SEDITION LAWS, and the names of the various political parties of the time), serving for a time on the State Council, and delivering a eulogy on Washington before the legislature. He declined the presidency of Harvard in 1804. He was an orator by inspiration, studying his subject and taking notes to expand on the moment, and full of flashing epigrams and pregnant laconics. A large public school in Dedham Centre commemorates his name. ('Works and Life,' 1 vol. 1809; 2 vols. 1854, by his son Seth; selected speeches, four new, 1 vol. 1871, by his grandson.)

Ames, James Barr, professor of law: b. Boston, 22 June 1846. Graduated at Harvard in 1868, the Law School, 1872. Instructor in history, Harvard, 1872–3; associate professor of law, 1873–7; professor of law since 1877, and dean of the law school since 1895. He is the author of numerous articles in the 'Harvard Law Review' and other legal periodicals, and has compiled collections of cases on torts, pleading, partnership, notes and bills, and suretyship.

Ames, Joseph, painter: b. Roxbury, N. H., 1816; d. New York, 30 Oct. 1872. Though wholly self-taught he early began portrait-painting, opened a studio in Boston, and had success enough to obtain means to go to Rome and study. While there he painted a fine portrait of Pius IX. He was elected member of the National Academy of Design, 1870, and soon had more orders than he could fill. Some of his best known portraits are those of Ristori, Prescott, Emerson, Rachel, and President Felton of Harvard. 'Maud Muller' and 'The Death of Webster' are his best known ideal paintings.

Ames, Joseph Sweetman, professor of physics: b. Manchester, Vt. 3 July 1864. He graduated at Johns Hopkins in 1886 and is professor of physics there. He is author of 'Theory of Physics' (1897); 'Manual of Experiments in Physics' (1898); 'Free Expansion of Gases' (1898); 'Induction of Electric Currents' (2 vols. 1900); editor 'Scientific Memoir Series,' 'Fraunhofer's Papers'; assistant editor 'Astrophysical Journal,' 'American Journal of Science.'

Ames, Mary Clemmer, American journalist and author: b. Utica, N. Y., 1839; d. 18 Aug. 1884. Educated in Westfield, Mass., she began very young to write for the Springfield *Republican;* then removed to Washington and became for many years a regular weekly correspondent of the New York *Independent,* her 'Woman's Letter from Washington' in which made her one of the best known and most influential woman writers in the country. Her style, especially on attractive masculine personalities, was somewhat Oriental; but she was honest and sincere in a time of pervasive lobbyism and self-seeking. She wrote also biographical sketches of the Cary sisters, Emerson, Longfellow, Charles Sumner, Margaret Fuller, and George Eliot; 'Ten Years in Washington' (1871); 'Outlines of Men, Women, and Things' (1873); the novels 'Victoria' (1864), 'Eirene' (1870), and 'His Two Wives' (1874); and a volume of poems (1882). She married early Rev. Daniel Ames, and was divorced; in 1883 Edmund Hudson, proprietor of the 'Army and Navy Register.' Her home in Washington was long a social and literary centre. (Works, Boston, 1885; memorial by her husband, 1886.)

Ames, Nathan P., American manufacturer: b. 1803; d. 23 April 1847. In 1829 he established cutlery works at Chicopee Falls, Mass., which attained a national reputation, their swords especially being largely bought by the United States. In 1834 he removed the works to Cabotville (Chicopee), where he lived and died; and incorporated with others the Ames Mfg. Co., which in 1836 added a bell and bronze cannon foundry that had equal fame and furnished the larger part of the government's brass cannon in the Civil War, as well as the bronze statues of De Witt Clinton in Greenwood Cemetery, Brooklyn, N. Y., of George Washington in Union Square, New York, and of Benjamin Franklin in School Street, Boston. The works supplied the British government just before the Crimean war with machines for making muskets.

Ames, Oakes, manufacturer and promoter: b. Easton, Mass., 10 Jan. 1804; d. 8 May 1873. The son of a blacksmith who had become a manufacturer of highly reputed picks and shovels, he trained himself in his father's works, and with his brother joined the firm as Oliver Ames & Sons. The opening up of California in 1848 and Australia in 1851 by the gold dis-

coveries created an immense demand for their goods in mining, settlement, and railroad building, which raised the firm to the front rank in business and wealth; and in the Civil War they had great contracts for shovels, swords, etc. Mr. Ames was in the Massachusetts executive council 1861, and congressman 1862 till death. In 1864 the failure of attempts to carry through the nationally exigent Pacific Railroad led President Lincoln's government to call on Mr. Ames to undertake it. He risked financial ruin if it failed, investing $1,000,000 and making his whole fortune responsible for the rest: it could not be expected that he should forego a corresponding profit if it succeeded. The work was finally accomplished by organizing a construction company (see CREDIT MOBILIER OF AMERICA), which paid itself largely in stock and bonds of the Union Pacific, practically making the two companies one, and enabling the former to charge the latter its own prices for work and supplies, the government paying the bills. Credit Mobilier stock became enormously valuable, and the directors were charged with cheating the government and using the stock to buy congressional support for the fraud. Mr. Ames' anomalous position as congressman, director in both companies, contractor for immense supplies to the railroad, and the ablest manager of the whole enterprise, caused the chief fury of the assault to fall on him; and in the tremendous public scandal and investigation which followed he was censured by the Forty-second Congress and died shortly after. His son Oliver (q.v.), however, induced the Massachusetts legislature to re-examine the case, and on 10 May 1883 (the 14th anniversary of the completion of the railroad) it passed a resolution exonerating Mr. Ames. The Union Pacific Railroad erected a monument to his memory at Sherman, Wyoming, the crest of the road, 8,550 feet above the sea.

Ames, Oliver, manufacturer, brother of Oakes above: b. Plymouth, Mass., 5 Nov. 1807; d. 9 March 1877. His brother's partner, he was a sharer in all his business enterprises; president *pro tem.* of the Union Pacific Railroad 1866–8, formal president 1868–71; a director in the Credit Mobilier. After his brother's death he became head of the manufacturing firm. He was a member of the State Senate 1852 and 1857.

Ames, Oliver, manufacturer, son of Oakes above: b. North Easton, Mass., 1831; d. 1895. He was trained in his father's works, and as his heir spent several years in paying off the obligations of millions of dollars incurred by the Union Pacific Railroad and other undertakings. Entering public life avowedly to vindicate his father's memory, he was lieutenant-governor of Massachusetts 1882–6; in 1883 obtained the vindicatory resolution he sought; and 1886–8 was governor.

Ames, Samuel, jurist: b. Providence, R. I., 6 Sept. 1806; d. there 20 Dec. 1865. Graduated at Brown, 1823; studied law with Judge Gould at Litchfield, Conn. He served for many years in the Rhode Island State Assembly, being speaker 1844–5. He was elected chief justice of the State supreme court 1856, but resigned in 1865 on account of ill-health. In 1839 he married Mary Throop Dorr, daughter of Thomas W. Dorr, leader of the rebellion in 1842. Author and editor of 'Angell and Ames on Corporations,' and vols. 4–7 of the 'Rhode Island Reports.'

Ames, Iowa, city in Story County, on the Chicago & N.W. R.R. It is the seat of the State Mechanical and Agricultural College and has a public library, banks, churches, schools, and two newspapers. It was first settled in 1864. Pop. (1900) 2,422.

Amesbury, Mass., town in Essex County, situated on the Merrimac River and on the Boston & Maine R.R.; 27 miles north of Salem. It has manufactories of cotton and woolen goods, boots and shoes, machinery, and carriages, and was long the residence of the poet Whittier. The town was settled in 1630. Pop. (1900) 9,473.

Ametabola, those insects in which development is direct, there being no metamorphosis.

Am'ethyst (from the Greek *amethystos,* "not intoxicated"). In mineralogy (1) a violet or purple variety of crystallized quartz, the color being probably due to traces of manganese or iron. It is esteemed as a gem, and was worn by the Greeks in the belief that it lessened the intoxicating effects of alcoholic drinks upon its possessor. It is widely distributed, but specimens pure enough in color to be used as gems are not common. The finest amethysts come from Brazil, India, Siberia, Pennsylvania, and North Carolina.

(2) The precious (or Oriental) amethyst is a crystalline oxide of aluminum, violet in color from the presence of traces of some other metallic oxide, and very brilliant and beautiful. Mineralogically the Oriental amethyst is a variety of corundum (q.v.).

Amhara, äm-hä'rä, a district of Abyssinia, lying between the Tacazzé and the Blue Nile, but of which the limits are not well defined. The Amharic language, next to the Arabic the most widely used of all the Semitic languages, has gradually gained ground in southern and central Abyssinia, and has become the court language. It has a literature of its own, including a version of the Scriptures.

Amherst, Jeffery, Baron, British soldier remembered for his American services: b. Kent, England, 29 Jan. 1717; d. 3 Aug. 1797. He was a duke's page, by his favor entering the army as ensign at 14, and became Gen. Lord Ligonier's aide; served through the war of the Austrian Succession, 1741–8, and was at Dettingen (1743), Fontenoy (1745), and Roncoux (1746); in the Seven Years' war beginning 1756 he was at the French victory of Hastenbeck, 1757. He had become noted as a brilliant soldier and ranked as lieutenant-colonel; in 1758 Pitt selected him to co-operate with Prideaux in conquering Canada from the French, made him major-general, and gave him command of the expedition against Louisburg, which he speedily reduced, 27 July. In the following September he superseded Abercromby as commander-in-chief of the English forces in America and captured Crown Point and Ticonderoga the following year. On 8 Sept. 1760 he captured Montreal and ended the French dominion in Canada. For this he was made governor-general of the British possessions in America, thanked by Parliament, and made a Knight of the Bath. But in face of Pontiac's conspiracy (1762) he failed,

as other English commanders had so often before, from insisting on conducting Indian like European warfare, and despising the American militia and American experience. But as American trivialities like Pontiac's war were unknown or unregarded in England, Amherst on his return in 1763 was received with immense enthusiasm as the conqueror of Canada; and as he was also a favorite of George III., and actively supported the policy of coercing the colonies through the years before the Revolution, his honors did not cease. He was titular governor of Virginia 1763-8, without going there, governor of Guernsey from 1770 on, privy councilor, 1772 on, 1772-82 and 1783-93 commander-in-chief of the British army, and was made a field marshal on resigning his command. In 1776 he was raised to the peerage. In 1780 he took an active and most humane part in suppressing the London "no popery" riots.

Amherst, port of entry and capital of Cumberland County, Nova Scotia, Canada, situated on an arm of Cumberland Bay, an extension of Chignecto Bay, the extreme northeastern arm of the Bay of Fundy; on the Intercolonial Railway, 138 miles north by west of Halifax, Nova Scotia, and about midway between that city and Saint John, New Brunswick. It was formerly called Fort Lawrence. Amherst is the centre of a rich agricultural and lumbering district; has factories, iron-foundries, tanneries, and ship-building establishments; and has an especially large trade in lumber and ship-building. Some of the richest coal mines in the Province are near here, and grindstones and gypsum are quarried in the vicinity. The county and railway buildings, the churches, and hotels are substantial structures. Amherst has a bank, and daily, semi-weekly, and weekly newspapers. Pop. (1901) 4,964.

Amherst, Mass., a town in Hampshire co., situated on the Boston & Maine and the Central Vermont R.R.'s, 23 miles northeast of Springfield. It has manufactories of paper, straw and palm-leaf hats, and leather, and is best known as the seat of Amherst College (q.v.), the State Agricultural College, and the State Experiment Station. Pop. (1900) 5,028.

Amherst College, at Amherst, Mass., one of the best known and most influential of New England colleges, though it has kept to the older ideals of an all-round liberal education, neither workshop nor professional school, and has not attempted to broaden into a university with specialized departments. As with all the earlier United States institutions of learning, the objects and impelling causes of its foundation were religious. It was started by an association of Congregational ministers who first took action in 1815, and was based on Amherst Academy, opened December 1814, and for many years one of the foremost academies in Massachusetts. The trustees of the academy were long the trustees of the college also, and the original plan was merely to endow a professorship of languages there to train educated ministers. They then enlarged it to a charity fund for "the classical education of indigent young men of piety and talents" for the ministry. A convention of the churches in western Massachusetts on 29 Sept. 1818 located the new institution at Amherst; the cornerstone was laid 9 Aug. 1820, and the institution opened 18 Sept. 1821. For some years the intention was to incorporate Williams College with it; but on a petition to the legislature permission to remove Williams was refused. The first president was Rev. Zephaniah Swift Moore, who died 29 June 1823 largely as a result of overwork. He was succeeded by Rev. Heman Humphrey, who retired in 1845, when the institution was threatened with bankruptcy, and its members and friends hardly expected to maintain it as anything more than an academy, and was succeeded by Rev. Edward Hitchcock, then professor of natural theology and geology there, and considered the foremost of American geologists. In his nine years' tenure he greatly extended the reputation of the college and saw it much more prosperous, and by his firm but conciliatory spirit, his weight of character, and sagacity of policy, gave it more internal unity and outside friendship. He resigned the presidency in 1854, but retained his professorship and was succeeded by Rev. William Augustus Stearns, who died in 1876: an able and excellent business man and administrator, and sound conservator of the college interests. His successor, Rev. Julius H. Seelye, who held office till 1890, placed it within its chosen boundaries alongside the best of other colleges: his reputation as scholar, publicist, educator, and humanitarian was more than national and drew the best class of pupils there. He resigned in 1890 from failing health, and has been succeeded by Merrill Edwards Gates to 1899, and Rev. George Harris, the present president. The college in 1902 had 36 professors and 410 students, and had graduated over 4,200 in all, of whom considerably over half had become clergymen or teachers. It had a library of over 75,000 volumes and very remarkable scientific museums; President Hitchcock's private collection of fossil footmarks, or ichnological cabinet, the choicest in the world, and his admirable geological and mineralogical cabinet, greatly supplemented by Prof. Benjamin K. Emerson, "a Mecca to geologists and savants"; the Adams conchological and the Shepard meteoric collections; also the collection of Indian relics presented by Edward Hitchcock, Jr. It has likewise the Pratt gymnasium and natatorium, athletic field, and college hospital, presented by the sons of Charles Pratt of Brooklyn, N. Y. Its income is about $110,000, and its scholarship fund has swelled by degrees to $300,000, the income of which goes to indigent students.

Alfred S. Goodale,
Registrar.

Amice, or **Amict** (Lat. *amictus*, girt around), a vestment worn by priests in the Roman Catholic Church during the celebration of mass. After the general adoption of the cravat had rendered the amice unnecessary as a neck-cloth, it was retained for the significance which it had acquired as an emblem of the cloth wherewith the Saviour was blindfolded by the Jews the night before his crucifixion.

Amici, Giovanni Batista, an Italian savant: b. in Modena, 1786; d. 1864. He studied natural history at Bologna, and mathematics at Modena. He became professor of mathematics at the college of Panaro, and for some time general inspector of education in Modena, where in 1831 the Grand Duke of Tuscany appointed

him director of the Florence observatory, as successor of the celebrated comet-discoverer, Luigi Pons. This office he held until his death, publishing every year the result of his astronomical observations, at the same time contributing important papers on natural history to the *Memorie della Società Italiana.* Science is especially indebted to him for his improvement of the telescope, of several microscopes, and of the camera lucida, invented by Hooke and Wollaston. He seems to have from his earliest life devoted much attention to optical instruments, and before he was 20 he made a telescope of a mixture composed by himself. In 1827 he made dioptric microscopes, which are sold with his name attached, and, notwithstanding the improved microscopes of Oberhäuser, are still in great favor. He was assisted in his labors by his son, Vincenzo Amici, who is professor of mathematics at the University of Pisa.

Amicis, Edmondo de, Italy's foremost 19th-century descriptive writer: b. Oneglia, of Genoese parentage, 21 Oct. 1846. Educated at Coni and Turin, he attended the Modena military school; entered service 1863 as sub-lieutenant, acted against the Sicilian brigands, and served through the Austro-Prussian war of 1866, being at Custozza 24 June. He remained in the army till the occupation of Rome in 1870; but his literary vocation was plain. In 1867 he took charge of a Florentine paper, *L'Italia Militare.* In 1868 his first volume, 'Military Sketches,' short stories of the phases of a soldier's life, had sweeping success and marked him as the coming Italian litterateur; and in 1871 he settled at Turin and devoted himself to authorship. His next work was 'Recollections' (of 1870–1), dedicated to the youth of Italy; a fresh collection of stories followed. But a craving for travel turned him into the path which has given him his greatest fame: the foreign world at least knows him mainly by the brilliant, glowing volumes describing the countries of Europe and other continents he visited, their national characteristics and habits, and, most of all, the springs of their life and thought. They are enthusiastic, sympathetic, optimistic, full of sensuous delight in beauty, rich in color, and vivid in clearness of portrayal; but they exhibit too a marvelously keen analytic power as well as acute photographic sensitiveness to impressions and marvelous literary skill in translating them into language. The greatest of these perhaps is 'Holland' (1874), a singularly fine analysis of the essence of Dutch life and the sources of Dutch art in that life; others are 'Spain' (1873), 'Recollections of London' (1874), 'Morocco' (1876), 'Recollections of Paris' (1878), 'Constantinople' (1878). He published also in these times 'Literary Portraits' (1881), sympathetic studies of Daudet, Zola, Dumas Jr., Augier, Coquelin, and Déroulède; 'The Friends,' on friendship in general (1882); historical novelettes, a collection in part old, entitled 'The Gate of Italy' (1884); 'On the Ocean' (1889). Later, educational and social problems deeply occupied his mind: his 'Cuore' (Hearts; Englished as 'The Heart of a Schoolboy'), a juvenile in which a pupil tells the events of a school year day by day, has sold nearly 200,000 copies in Italy; a novel for adults on similar lines is 'The Workmen's Mistress' (1895); followed the same year by 'The Romance of a Master' (1895), which has a strong socialistic bent. He avows himself that he thinks socialism the only available spring of a vital Italian literature now. His latest works are 'Everybody's Wagon' (1899), 'Memories' (1899), 'Hope and Glory' (1900), and 'Records of Infancy and School' (1901).

Amide (am'id; from *ammonia,* + *ide*), in chemistry, a general name for a class of bodies which may be regarded as derived from ammonia, NH_3, by replacing one or more of the hydrogen atoms in that substance by an equal number of monovalent acid radicals. Thus formic acid, H.CO.OH, may be regarded as a hydrate of the acid radical HCO; and the compound $HCO.NH_2$, which is known as "formamide," and is obtained by the action of ethyl formate upon ammonia, may be regarded as derived from ammonia by the substitution of the radical HCO for one of the hydrogen atoms in NH_3. Similarly, acetic acid, $CH_3.CO.OH$, may be regarded as a hydrate of the radical "acetyl" (C_2H_3O); and acetamide, which has the formula $C_2H_3O.NH_2$, and is produced by the action of ethyl acetate upon ammonia, may be regarded as derived from ammonia by the substitution of the radical "acetyl" for one of the hydrogen atoms in the ammonia.

Taking the general formula of a normal fatty acid as X.CO.OH, where X represents an alcohol radical (see ALCOHOL), an amide may be formed by substituting the monovalent acid radical, XCO, for one of the hydrogen atoms in NH_3. The resulting substance, $XCO.NH_2$, is called the "primary amide" of the acid radical XCO. By the further substitution of XCO for one of the atoms of hydrogen remaining in the primary amide, a "secondary amide" of the same acid radical is obtained, having the formula $(XCO)_2.NH$. It is evident that a "tertiary amide," having the formula $(XCO)_3.N$, is also possible.

For some purposes it is convenient to regard the primary amide, $XCO.NH_2$, of the monobasic acid X.CO.OH, from the opposite point of view; namely, as derived from the acid by the substitution of the radical NH_2 for the hydroxyl group OH. Obviously the result is the same in either case; but this latter view makes the deportment of dibasic acid radicals easier to describe. Thus in the dibasic acid $Y(CO.OH)_2$ (where Y is a divalent radical), the first result of the substitution of NH_2 for OH is the formation of the body $Y(CO.OH).(CO.NH_2)$, which is both an acid and an amide,— an amide because it is obtained by the substitution of NH_2 for OH, and an acid because it still contains one molecule of hydrogen that is replaceable by a monovalent metal or radical (namely, the molecule of H in the OH). Bodies of this type are called "amic acids."

If the molecule of OH remaining in an amic acid is replaced by a further substitution of NH_2, the resulting substance, $Y(CO.NH_2)_2$, is called a "di-amide," and may be regarded as formed from two molecules of ammonia by the substitution of the divalent acid radical $Y(CO)_2$ for one third of the total hydrogen present in those molecules.

The chemistry of the amides is very involved. They are mostly solid bodies, neutral to litmus, but capable of forming compounds with acids. The most familiar example of the class is the primary amide of acetyl, or "acetamide." This

substance, which is usually obtained by the dry distillation of acetate of ammonium at temperatures exceeding 375° F., has the formula $C_2H_3O.NH_2$, as noted above, and forms hexagonal crystals. It melts at about 180° F., boils at about 432°, and is quite soluble in water. Diacetamide, $(C_2H_3O)_2.NH$, and triacetamide, $(C_2H_3O)_3.N$, are also known. See AMINE; IMIDE; NITRILE.

Amido Acids, intermediary products in the metabolism of proteids. In the process of digestion notably, the proteids (albumens) undergo a gradual series of transformations whereby the complex proteid molecule is broken down into simpler and simpler compounds, until at the end of the process carbonic anhydride, water, urea, uric acid, ammonia, etc., are the results. While these end products of metabolism are well known, the intermediary products are the object of much inquiry. In the intestinal canal, under the prolonged action of the pancreatic juice ferments, simpler nitrogenous principles are found, leucine, tyrosine, aspartic acids — these belong to the general group of the amido-acids. Schutzenberger has described amido-acids of the (1) leucine class, $C_NH_{2N+1}NO_2$ — such as alanine, propalinine, butalanine; (2) of the acrylic series $C_NH_{2N-1}NO$, (3) amido-acids of the gluco-protein class, sweet in taste, with the general formula $C_NH_{2N}N_2O_4$; (4) amido-acids such as tyrosine, tyroleucine, and glutaminic acid. Amiel, Henri Frederic, a distinguished Swiss essayist, philosophical critic and poet: b. in Geneva, 27 Sept. 1821; d. there 11 March 1881; was for five years a student in German universities, and on his return home became professor of philosophy in the Geneva Academy. He is author of several works on the history of literature, as 'The Literary Movement in Romanish Switzerland' (1849); 'Study on Mme. de Staël' (1878); and of several poems, among them 'Millet Grains' (1854). But his fame rests principally on the 'Journal,' which appeared after the author's death.

Amiens, ȧ'myăɴ', an old French city, once the capital of Picardy, and now of the department of Somme, on the many-channeled navigable Somme, 81 miles north of Paris by rail. Its fortifications have been turned into charming boulevards, but it still retains its old citadel. The Cathedral of Notre Dame is a masterpiece of Gothic architecture. Begun in 1220, or a little later than Salisbury Cathedral, it is 470 feet long, and has a spire (1529) 426 feet high; but its special feature is the loftiness of the nave, 141 feet. In his little work called 'The Bible of Amiens,' Ruskin says this church well deserves the name given it by Viollet-le-Duc, "the Parthenon of Gothic architecture," and affirms that its style is "Gothic, pure, authoritative, and unaccusable." Other noteworthy buildings are the Hôtel de Ville (1600–1760), in which the Peace of Amiens was signed; the large museum (1864), in Renaissance style; and the public library, founded in 1791 and containing 70,000 volumes. Amiens has considerable manufactures of velvet, silk, woolen, and cotton goods, ribbons, and carpets. Peter the Hermit and Ducange were natives, and there are statues to both of them. The "Mise of Amiens," was the award pronounced by Louis IX. of France, in 1264, on the controversy between Henry III. of England and his people as to the "Provisions of Oxford." The Peace of Amiens (27 March 1802) was a treaty intended to settle the disputed points between England, France, Spain, and Holland. By it England retained possession of Ceylon and Trinidad and an open port at the Cape of Good Hope; the republic of the Ionian Islands was recognized; Malta was restored to the Knights of St. John; Spain and Holland regained their colonies, with the exception of Trinidad and Ceylon; the French were to quit Rome and Naples; and Turkey was restored to its integrity. In the Franco-Prussian war, on 27 Nov. 1870, General Manteuffel inflicted, near Amiens, a signal defeat on a French army 30,000 strong, and three days later the citadel surrendered. Pop. (1903) about 92,000. For a recent account of the cathedral see T. Perkins' 'The Cathedral of Amiens' (1902).

Amina, the sleep-walking heroine of Bellini's opera 'La Sonnambula.'

Amine (am'in; from *ammonia* + *ine*), a general name for a compound formed by replacing one or more of the hydrogen atoms of ammonia by an equivalent number of metallic atoms or basic organic radicals. (Compare AMIDE.) As in the case of the amides, a given monovalent radical can form three compounds of this sort according as it replaces one, two, or three of the hydrogen atoms of the original ammonia. For example, the monovalent basic radical "ethyl," C_2H_5, forms primary ethyl amine (or "ethylamine"), $C_2H_5.NH_2$, when it replaces one atom of H in NH_3; secondary ethyl amine (or "diethylamine"), $(C_2H_5)_2.NH$, when it replaces two atoms of H; and tertiary ethyl amine (or "triethylamine"), $(C_2H_5)_3.N$, when it replaces all three of the hydrogen atoms in the ammonia. The base by which the hydrogen in the ammonia is replaced need not be organic. Potassium, for example, may replace an atom of it, with the formation of potassium monamine (or "potassamine"), $K.NH_2$. A derivative of ammonia, in which one atom of the typical hydrogen is replaced by a monovalent acid radical, and another by a monovalent basic radical or by a monad metal, may be considered to be either an amine or an amide. Thus $CH_3.C_2H_3O.NH$, in which one atom of the hydrogen has been replaced by the basic radical "methyl" (CH_3), and another by the acid radical "acetyl" (C_2H_3O), may be described as a modified methylamine, or as a modified acetamide.

The simpler amines are strongly basic in character, and may be formed by the action of ammonia on the ethers of inorganic acids. They are mostly volatile or capable of distillation. When ammonia is added to a cold solution of a salt of an amine, the amine is expelled from its combination and precipitated.

The most important amines, in the arts, are methylamine (q.v.) and aniline (q.v.).

Amirante Islands, a group of small islands in the Indian Ocean, lying southwest of the Seychelles. They were taken possession of by Great Britain in 1814 and form a dependency of Mauritius. They produce cocoa-nuts, and turtle and fish are abundant. About six are inhabited.

Amis et Amiles, a'me' za a'mel', a chanson of the Middle Ages, dating from about the beginning of the 13th century. The work con-

sists of 3,500 lines, in which are narrated the adventures of two friends.

Amistad Case, in United States history, one of the landmarks of the slavery question. The Spanish government, by decree of December 1817, forbade the importation of slaves from Africa into its dominions after 30 Dec. 1820, on penalty of confiscation of the slave-ship and immediate freeing of the negroes. The trade nevertheless went on under transparent disguises. In the spring of 1839 the slave-hunters in Africa made a large capture of Sierra Leone natives, including their chief Cinque, and sent them to Havana; where two months afterward two Cuban planters, Pedro Ruiz and José Montez, bought 38 youths and men, three girls, and a boy, and shipped them on 27 June for Guanaja, Puerto Principe, on the schooner L'Amistad, under passport from the governor of Cuba obtained by falsely alleging that they were domestic slaves. Cinque organized a plan for revolt, and when four days out they rose, killed the captain and one of the crew, wounded two others in the contest, and forced the remaining whites to surrender; but they did them no violence, and set all on shore except the two planters, whom they managed to make understand that they must steer for Africa. These gradually changed course in the nights and fogs, and brought the vessel north off Culloden Point (near Montauk), at the east end of Long Island, where on 26 August she was noted as "suspicious" by Lieut. Gedney of the coast survey, on the brig Washington. He sent a boat to her, and one of the planters declared himself the owner of the negroes and claimed United States protection. Some of them had gone on land in a boat; Gedney seized them as under New York State jurisdiction, and the vessel as a "prize rescued from pirates," and brought them to New London, Conn. The negroes were committed for murder on the high seas, to be tried at the circuit court of 17 September at Hartford, and meantime lodged in New Haven jail. The planters claimed them as slaves, appealed to the Spanish minister Calderon, and he demanded their surrender of the United States district attorney for Connecticut. The latter wrote to the secretary of state (Forsyth of Georgia) asking if the negroes under treaty with Spain might not be surrendered before the court sat; the secretary transmitted the question to the President (Van Buren), but warned the district attorney to take care that no court whatever put the vessel, cargo, or slaves (*sic*) beyond the control of the Federal executive. Meantime the anti-slavery interest had bestirred itself and secured funds, able counsel, and an interpreter of African; and the circuit court (Judge Thompson) decided on the 23d that the killing of the captain of the L'Amistad, being an incident of the slave trade, was not a crime against the law of nations. The negroes were remanded to jail till the district court in November should decide whether they were free or slave. The next day the United States attorney-general, Felix Grundy of Tennessee, was ordered to prepare an official opinion on the Spanish minister's request and the claim of Gedney *et al.* for prize money. He replied in November that ship, cargo, and negroes should be surrendered according to Art. 9 of the treaty of 27 Oct. 1795, as the United States under international law had no power to investigate the truth of facts stated in Spanish official papers,— in other words, whether the governor's passport was obtained by fraud, and the negroes were free according to the Spanish law already cited; though hardly one could speak a word of European and none much more, and the planters were obviously perjured in swearing ignorance of their being recently imported. But this article any way related only to vessels and goods rescued on the high seas from pirates; and under this interpretation the negroes were at once the pirates and the cargo, and had committed piracy in seizing themselves from their owners. The Spanish minister protested that no United States court had any jurisdiction. The administration, not daring to take the case out of its courts, went as far as it could by ordering the district attorney to act as legal adviser to the planters and file another indictment for them with new pleadings; sent a vessel to lie off New Haven in order to carry the negroes back to Cuba as soon as the district court pronounced them slaves, as was taken for granted (this was the first trial for violating the slave-trade laws that had taken place except in slave States, where of course no convictions were ever found), and to do it instantly unless an appeal were interposed, which was "not to be taken for granted"; ordered that Gedney and his associate Meade accompany it to give evidence in court; and that these directions be kept secret. But the anti-slavery counsel had no difficulty in showing that kidnapping foreigners was not only not protected by United States or even Spanish law, but was directly contrary to both (the anti-slavery doctrine outside the courts was that the kidnapped had a natural right to kill their captors if they could, and a legal right to hold ship and cargo as prize in such case, and the United States had no right to interfere); and the court pronounced them free, and ordered them delivered to the United States executive to be sent back to Africa. The plaintiffs at once appealed to the supreme court, and the administration continued its partnership in a private suit. The case of the negroes was argued in February and March 1841 by John Quincy Adams, who had previously introduced resolutions into the House directing the President to report to Congress the authority by which Africans charged with no crime were held in custody; Roger Sherman Baldwin, the district attorney, admitted in open court that they were newly from Africa when bought: and on 9 March the court (Taney, C. J.) pronounced them illegally held as slaves and liable to no punishment for their acts. The case roused the fiercest excitement in both the free and slave sections of the country. In 1844 the astounding bill was reported by the chairman of the House committee on foreign affairs to pay Ruiz and Montez $70,000 compensation; but it was laid on the table and never reappeared. This ends the "case," but a word may be added on the negroes. They were removed to Farmington, Conn., well cared for, and instructed in the rudiments of education by a competent professor. Cinque kept them under stern discipline; they were excellently behaved and much liked; and some of them, being unusually quick of intelligence, were exhibited for proficiency in New England towns. About the end of November they were sent back to Africa with some missionaries, and a mission was afterward established in the district.

Amitosis. See MITOSIS.

Amlwch (pronounced *Amlook*), a seaport town in North Wales, on the north coast of the island of Anglesey, and 14 miles northeast from Holyhead. The harbor is partly cut out of the solid rock. There are copper mines near the town, and mining is said to have been carried on here by the Romans. Pop. (1901) 5,308.

Ammanati, Bartolomeo, a sculptor and architect: b. Florence, 1511; d. 1592. His chief work was the Trinity bridge over the Arno at Florence.

Ammen, Daniel, American naval officer: b. Brown County, Ohio, 15 May 1820; entered the United States navy 7 July 1836 as midshipman. He was in the Wilkes exploring expedition around the world 1838–42, in the East India squadron, and on the coast survey; on the expedition to the Paraguay River 1853–4. He commanded the Seneca at the capture of Port Royal, 7 Nov. 1861; promoted to commander 21 Feb. 1863; in charge of the Patapsco at the assault on Fort Macallister, 3 March 1863, and on Fort Sumter, 7 April; commanded the Mohican in the attacks on Fort Fisher, December 1864 and January 1865. He was commissioned captain 1866, was chief of the bureau of yards and docks 1869–71, and of the bureau of navigation till 11 Dec. 1877, when he was made rear-admiral on the retired list. He designed the Ammen life raft and the ram Katahdin. He wrote 'The American Inter-Oceanic Ship Canal Question' (1880); 'The Atlantic Coast,' (1883); 'Country Homes and their Improvement'; 'The Old Navy and the New' (1891).

Ammergau, am'mer-gou, a district or *gau* on the river Ammer in Upper Bavaria. The inhabitants are occupied in making figures of saints, crucifixes, toys, etc., of wood, ivory, and glass, from which a considerable trade arises, having its centre in the villages of Ober and Unter Ammergau. The former village is famous on account of the Passion Play (q.v.).

Am'meter. See GALVANOMETER.

Ammon, an Egyptian deity, whose worship spread all over Egypt and other parts of north Africa, and many parts of Greece. The Egyptian hieroglyphic monuments call him Amun, the Greeks identified him with their supreme god Zeus, while the Romans regarded him as the representative of Jupiter. His worship centred in the Egyptian Thebes, which the Greeks therefore called Diospolis or the City of Zeus. He is represented as a ram, as a human being with a ram's head, or simply with the horns of a ram. His most celebrated temple was in the Oasis of Siwah in the Libyan desert.

Ammonia (supposed to be so called because originally prepared from the dung of camels near the temple of Ammon, in Egypt), a gaseous compound of hydrogen and nitrogen, having the formula NH_3. It may be formed in small quantities by the direct combination of its elements under the influence of the silent electric discharge; but in the arts it is commonly prepared by the decomposition of nitrogenous matter. Formerly it was manufactured in large quantities by the destructive distillation of horns, hoofs, and hides, and from this fact it was known as "spirits of hartshorn." It is now chiefly obtained as a by-product in the manufacture of coal-gas. Coal suitable for the manufacture of gas contains nitrogen, often to the extent of 2 per cent of its weight; and in the distillation of such coal the nitrogen combines with a portion of the hydrogen that is also present, and is driven off in the form of ammonia; or more often it combines with the sulphur present and is obtained in the form of a sulphate. Salts of ammonia also occur in nature, sometimes in considerable quantities. In Tuscany ammonia sulphate is obtained as a by-product in the manufacture of boric acid. See BOUSSINGAULTITE; LARDERELLITE; MASCAGNITE.

Ammonia (NH_3) is a colorless gas at ordinary temperatures and pressures, but at 60° F. it condenses into a colorless and expansible liquid upon the application of a pressure of about seven atmospheres. At the freezing point of water a pressure of 4.4 atmospheres suffices to liquefy it; and at about 29° below zero, F., it condenses into a liquid at ordinary atmospheric pressure. Ammonia thus liquefied by pressure is much used, in the arts, for the production of low temperatures and the manufacture of artificial ice. (See REFRIGERATION, *Artificial.*) It freezes at about 103° below zero, F., into a white crystalline solid. Liquid NH_3 dissolves the alkali metals without chemical change, forming blue solutions.

Ammonia gas is very soluble in water at ordinary temperatures, the solution constituting the so-called "ammonia" or "aqua ammonia" that is familiar in every household. At 32° F. and at ordinary atmospheric pressure water will absorb 1,148 times its own volume of NH_3; and at 68° F. it will absorb 740 times its own volume.

Both ammonia gas and its solution in water possess strongly alkaline properties, turning red litmus paper blue and combining with acids to produce definite salts. The solution of ammonia gas in water is attended by a considerable development of heat, and it is usual to consider that a definite compound of ammonia and water is formed. The formula of this compound may be written $NH_3.H_2O$, but many considerations suggest that $NH_4.OH$ is a better and more logical form. NH_4 is here considered to be a radical, analogous in its chemical deportment to the familiar alkali metals sodium and potassium. According to this view ordinary "aqua ammonia" would be regarded as a solution of the hydrate of the radical NH_4; and for many years past chemists have admitted the existence of such a radical, which they have called "ammonium." Upon adding hydrochloric acid to a solution of ammonia gas, a compound known as "sal ammoniac" is obtained, which is used largely in electric batteries that are intended for open circuit work. The reaction by which this substance is formed may be written $NH_3 + HCl = NH_3.HCl$; or if the existence of a definite hydrate in the "aqua ammonia" is admitted, we may write the reaction $NH_4.OH + HCl = NH_4.Cl + H_2O$, in which case the reaction is in all respects analogous to that by which potassium chlorid (for example) is formed when hydrochloric acid acts upon potassium hydrate: $KOH + HCl = KCl + H_2O$. All the other salts that are formed by the combination of ammonia with acids can be similarly expressed by admitting the existence of the radical NH_4 and treating it, in the formulæ, as though it were a metal of the alkali group. All the "ammonium" compounds are isomorphous with the corresponding potassium compounds.

Aqua ammonia, or "caustic ammonia" (as it is sometimes called), is used for many purposes in the arts, notably in the production of soda by the ammonia process (see SODIUM), and in dyeing and calico-printing. Large quantities of the sulphate are used in fertilizers and in the manufacture of ammonia alum (see ALUM). The chloride of ammonium is used (as above noted) in certain common forms of electric batteries, and also in soldering, in dyeing, and in many minor ways. The carbonate is largely used in the manufacture of baking powders and for scouring wool.

Ammonia is expelled from all of its compounds by quicklime, and the usual test for ammoniacal compounds consists in heating the substance to be examined, together with caustic lime or caustic soda or potash. If ammonia is present in any considerable amount it is liberated by this treatment and may be recognized by smell or by its action on litmus paper. Nearly all of the compounds of ammonia are readily soluble in water, the acid tartrate and the double platinic chloride being the chief exceptions.

Ammonia forms the starting point for an extraordinarily long list of compounds, many of which are exceedingly complicated. See AMIDE; AMINE.

Am'moni'acum is a gum resin derived from the stems of *Dorema ammoniacum,* a forest plant of Persia. Other species of *Dorema* yield similar products.

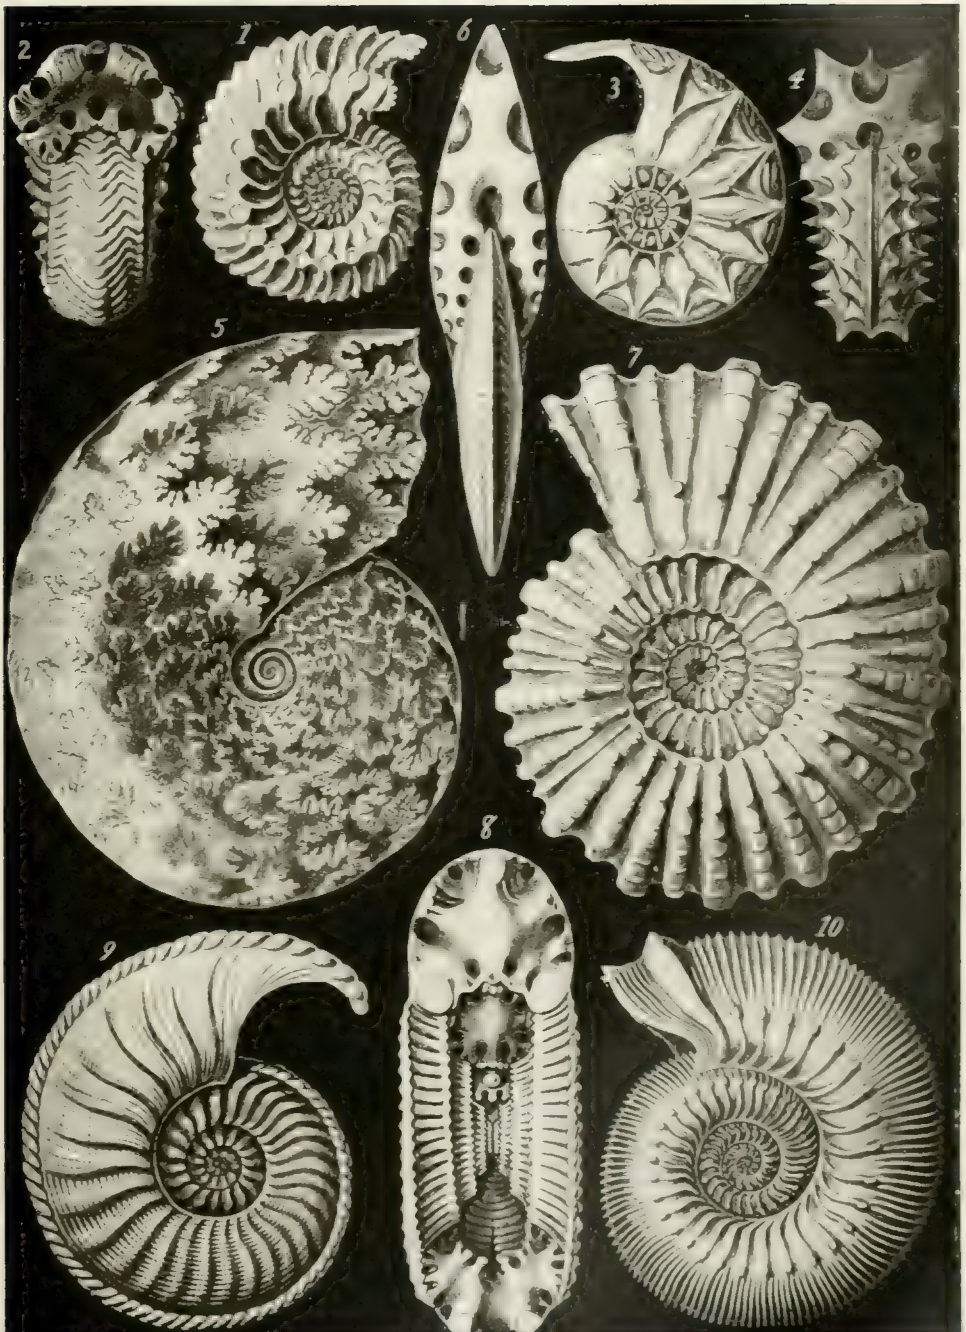
The plant has an abundant supply of milky juice which exudes spontaneously and hardens in various-shaped masses. Fine tears, varying in size from two to five mm. up to the size of a hazel-nut are obtained from insect-punctured wounds, while the so-called *ammoniacum amygdaloides* is obtained from the root of the plant.

Ammoniacum consists of a mixture of varying proportions of ethereal oils, 1 to 2 per cent, resins, gums, 65 to 70 per cent; and pectin-like bodies. Ash 20 per cent. A certain amount of water is always found in the commercial product. The ethereal oils are found in small quantities only, generally less than 10 per cent. It is soluble in carbon disulphide. The resin is to be distinguished from other resins in that its alcoholic solution gives a red reaction when added to a bromide of sodium solution, 30 gr. NaOH in Aq. Br. 20 gr. Aq. 1 liter. Umbelliferon would seem to be absent.

Ammonites, or "children of Ammon." In the cuneiform inscriptions their land is called Bit-Ammān, as if Ammān were a personal name; but Genesis says Ben-ammi, and Ammi was perhaps a local god. Their land was in the eastern part of the district now called Belka, on the northeast of the Dead Sea next the desert; its capital Rabbah or Rabbath-Ammon. Their real history begins with Saul, though Jephthah the freebooter is said to have delivered Israel from them, and one tradition represents Balaam as an Ammonite — but this is thought a later excuse for excluding them from the Jewish body. They were in a state of chronic border warfare with the Hebrews, their close kinsmen, and speaking a closely related dialect. Nahash, king of Ammon, besieges Jabesh-Gilead (1 Sam. xi.), and offers terms for its capitulation on condition of putting out the chief men's right eyes,— but Saul wins a crushing victory over the besiegers. David as Saul's enemy is well treated by Nahash; but when he takes Saul's place the old feelings are resumed. Hanun, the son and successor of Nahash, treats David's messengers of congratulation with gross contumely (2 Sam. x.); David wins a victory over them and the Syrian allies they have called in, and exacts a frightful vengeance from them, putting his captives to the torture quite in the Assyrian fashion, and leaving us to infer that there was little to choose in savagery. They probably recovered their independence after Solomon's death. Later they were subjugated by the Assyrians, as the inscriptions of several kings evince. Under Jeroboam II. they make incursions into Gilead and are blamed for inhumanity. After the Israelitish deportation of 734 they occupied the land of Gad; under Jehoiakim they are incorporated into Judah; under Zedekiah they are allied with him against Assyria, but seem to have drawn out in time for safety, and Israelitish fugitives find refuge with their king Baalis. Later they intermarried with the Jews, and there was a village of them in Benjamin; Judas Maccabæus defeated them; but they were gradually absorbed by invading Arab tribes. Their great local god was Milcom.

Ammonites, the general name for the fossil cephalopod mollusks of the order *Ammonoidea,* given originally because of a fancied resemblance of the coiled specimens first known to a ram's horn, the symbol of Jupiter Ammon. Subsequently it served as a generic name for a group, but this has been abandoned in the light of later information. The *Ammonoidea* are one of the two orders of chambered tetrabranchiate cephalopods, the other being the *Nautiloidea* (see NAUTILUS). Their remains are found fossil in marine Palæozoic rocks from the Devonian to the close of the Mesozoic Age. More than 5,000 species have been described, grouped into about 100 families, and these into nine sub-orders in two divisions, (1) *Intrasiphonata* and (2) *Extrasiphonata.* The first group contains a single primitive (Devonian) sub-order having the siphuncle dorsally situated; the second contains all the remainder, which agree in having the siphuncle ventral. The classification is based upon the complexly lobed pattern of the sutures, or lines of union between the septa or partition walls of the chambers and the outer wall of the shell. (See CEPHALOPODA.) The shells of ammonites were typically coiled in a single plane and ran in size from an inch or two in diameter to two or more feet; but this varied greatly, even to partial or entire straightness. The surface of the shell, too, was in many cases smooth and polished or slightly ridged, while in others it was roughly ringed or covered with cross-lines, spikes, and tubercles, in handsome variety. Some shells were so compressed as to have the proportions of a watch; while others were almost globose.

As Hyatt states, ammonoids experienced a progressive evolution from the early Devonian until the upper Juras, when the group reached its summit of importance and was represented in great numbers and variety in all parts of the world: that is, when it attained the summit of its evolution in complexity of structure, form, and ornament. Ammonoids exist in great abun-



AMMONITES.

1, 2 **Ammonites cordatus.** 3, 4 Ammonites Coupei. 5, 6 Ammonites opulentus. 7 **Ammonites mammillaris.**
8 Ammonites cavernosus. 9 Ammonites rotula. 10 Ammonites Humphryi.

dance in the rocks of this period in the western United States, especially those of the irregular group called Ceratites, which succeeded the Palæozoic Goniatites, and other primitive forms. The Jurassic ammonoids show a mixture of retrogression with some progressive features. "Part of their losses are regained by the evolution of the vast number of forms and modifications during this period, but there are numerous localized signs of retrogression, due perhaps to unfavorable surroundings." Indications of this kind occur sporadically throughout the Jurassic time and become general in the Cretaceous period. Many of the later forms were openly or grotesquely coiled, or coiled only when young, becoming nearly or quite straight when they grew older, as in Ptychoceras, Turriteles, Scaphites, etc. These degraded "old-age" types were evidently due to the waning forces of life or to disease, because similar though much less marked uncoiling of shells, due to unfavorable condition of the water, have been observed in the fresh-water Planorbis of Steinheim, Germany, and elsewhere. (See EVOLUTION; SENESCENCE.) Hyatt thus infers that there was in the European seas, at least, a widespread unfavorable change in their physical surroundings, "similar to but more extensive than that which affected European forms during the Lower Oolite," and to this influence he ascribes the uncoiling of the shells of Spiroceras and its allies. At the close of the Cretaceous period the ammonoids entirely disappeared. We thus see in the vast and more or less complete and continuous series of these beautiful shells, in which the imperfections of the geological record are less marked than in other groups, the process of rise, culmination, decline, and death of a type, presenting also beautiful illustrations of the biogenetic law (q.v.). The type begins with infantile and larval forms, then evolves youthful, mature, and finally old age forms, which present in their simple and closely coiled shells a return to the original simplicity of the infancy and childhood of the type.

Concerning the animals which made the shells, nothing is known except by inference. The growth of the shell begins with the formation of the primitive conically-shaped shell called "protoconch," and then the secondary shell begins to grow and becomes coiled up in one plane. Like the nautilus the mollusk lived in the outer chamber of its shell, from which it periodically advanced. The aperture of this outer chamber was closed when the animal withdrew into it, either by a single horny plate (*anaptychus*) or by a pair of calcareous plates (*aptychus*). The very earliest appear to have been swimmers, like the nautiloids; but the great bulk of the ammonites undoubtedly lived gregariously alongshore, where they crawled about, carrying or partly dragging their shells, and searching for the animal food upon which they subsisted. The learned Zittell points out that their shells were proportionately less bulky than those of the nautiloids, and correspondingly less buoyant; and the probability is that they swam little and were rarely active. There is reason to believe that in the case of some species the eggs were retained within the shelter of the living-chamber until they hatched, and that the young remained there until somewhat grown. See GONIATITES.

Bibliography.— Cook, 'Cambridge Natural History. Mollusks' (1895); Zittell-Eastman, 'Text-book of Palæontology,' Vol. I. (1900); Hyatt, 'Genesis of the Arietidæ' (Memoirs Mus. Comp. Zool., Vol. XVII., 1889); 'Phylogeny of an Acquired Characteristic' (Proc. Amer. Philos. Society, Vol. XXXII., No. 143, 1894); Wurtenberger, 'Studien über die Stammesgeschichte der Ammoniten' (Leipsic 1880), and numerous other papers; also articles by D'Orbigny, Neumayr, Pumpelly, Quenstedt, Sandberger, Suess, Waagen, White, Whiteaves, Wright and Zittel.

Ammo'nius Sac'cas, a Greek philosopher who lived about 175–250 A.D. Originally a porter in Alexandria, he derived his epithet from the carrying of sacks of corn. The son of Christian parents, he abandoned their faith for the polytheistic philosophy of Greece. His teaching was historically a transition stage between Platonism and Neo-Platonism. Among his disciples were Plotinus, Longinus, Origen, etc.

Ammonoosuc, the name of two small rivers in New Hampshire which rise in Coos County and flow in a southwest direction, emptying into the Connecticut River. The lower Ammonoosuc is about 100 miles long and the upper 75 miles long.

Ammophila, a grass common on sandy beaches, a coarse perennial, with running rootstocks. It is of value as a binder of loose sand and is employed for that purpose throughout the world, its destruction being forbidden in England under severe penalties.

Ammunition, the articles which are required in firearms and ordnance to render the mechanism effective. From the earliest period of settlement shot and bullets have been made by Americans. Lead was brought with them from England and Holland, and cast in molds, many of which are still preserved in old houses in New England, Pennsylvania, and Virginia. They differed only in size, so whether each projectile weighed an ounce or the twentieth of an ounce, the same plan was adopted. Shot-towers were invented at an early date. The metal, a compound of lead and arsenic, the latter forming one hundredth part, is melted at the top of a high tower and poured into a colander. The lead passes through in drops instead of streams, each assuming a perfectly spherical form, and falls into a basin of cold water, there being instantly chilled in the globular form. After this the shot are rolled down an inclined plane, those which are not truly spherical falling off at the sides, while the perfect ones continue in a direct course. The holes through which the liquid metal passes are from one thirtieth to one three hundred and sixtieth of an inch in diameter. Shot is much used for killing small game, which would be torn in pieces by a heavy bullet; and a shot-gun also requires less accurate marksmanship than a rifle. Bullets are still cast in molds, but in the factories this operation is performed with great celerity. The ridge caused by the meeting of the two parts is automatically removed by a knife. Swaging of bullets is also practised. The total quantity of shot made in New York annually is valued at $400,000, there being three shot-towers. Early in the 19th century no method was commonly known of getting

accurate results from a gun, but it was noticed that a bullet was nearly always flattened or smashed at the end nearest the powder. If the ball was large for the bore of the gun it reached its mark more certainly than if the bore was large. It was therefore the common practice for hunters to put a patch or wad around their bullet, which prevented the powder from falling out, and also kept the bullet straight till it had left the muzzle; and it was also discovered that if there were grooves inside the barrel which twisted more or less, a rotary motion was imparted to the bullet, which added much to its range and its powers of reaching its aim. This constituted the rifle, and after its method of construction became generally known no other weapon was used for hunting large game. They were used to some degree in armies even fifty years ago. Gradually the smooth-bore musket was driven out and soldiers were supplied alone with rifles. But another article was necessary before this could be completely accomplished. Until the second quarter of the century the fire which was required to be communicated to the powder came from a blow of the hammer of the gun upon a piece of flint. Frequently there was a miss. Percussion-caps were introduced about this time. They depended for their value upon the quality of igniting with a blow, their shape, like that of a cup, being only requisite in order to keep them on the nipple of the gun. They were much more certain in action than the flint had been, and soon drove it out everywhere. A later improvement in ammunition was by the introduction of cartridges, the powder and bullet being together. The metallic cartridge is an invention made in France about 1831 and introduced here shortly after. A great improvement was also made in France in 1845 in the shape of the bullet, which did not become known here till the time of the Crimean War. It was the Minié bullet, having for its peculiarity an elongation of the projectile. Hitherto all others had been round. The part which was foremost tapered to a point, but the rear was flat, as if the bullet had been cut from a round rod of lead. A heavier bullet was thus attained, a more thorough rotation was imparted, and little resistance was experienced from the air. The new projectile would carry twice the distance of the one it superseded, and would even at that point be more destructive. The total production of ammunition in the United States in 1900 was valued at $6,538,482; business was carried on in 35 establishments, which had 2,267 workmen, paid $1,110,482 in wages, and used materials valued at $4,645,850. See ARMAMENT OF THE WORLD; FIRE-ARMS; ORDNANCE.

Amnesia. See APHASIA.

Amnesty, an act of oblivion passed after an exciting political period. Express amnesty is one granted in direct terms. Implied amnesty is one which results when a treaty of peace is made between contending parties. Amnesty and pardon are very different. Amnesty is an act of the sovereign power, the object of which is to efface and to cause to be forgotten a crime or misdemeanor. A pardon is an act of the same authority which exempts the individual on whom it is bestowed from the punishment which the law inflicts for the crime he has committed. 7 Pet. (U. S.) 160. Amnesty is the abolition and forgetfulness of the offense; pardon is forgiveness. A pardon is given to one who is certainly guilty or has been convicted; amnesty, to those who may have been so.

Amnesty Proclamation. An act passed 25 Dec. 1868, granting amnesty to all who were guilty of treason against the United States or adhered to their enemies during the Civil War. This included domiciled aliens. But the proclamation did not entitle one whose property had been sold under the Confiscation Act of 1862 to reclaim the proceeds after they had been paid into the treasury of the United States.

Amnion. See FŒTUS.

Amœba, or PROTEUS ANIMALCULE, a protozoan classified as one of the rhizopods, which is present almost everywhere in fresh water, and sometimes in moist earth, and is commonly taken as the type of the unicellular animals. It is a mere drop of animated jelly (protoplasm, q.v.), hardly visible to the unaided eye, which under the microscope is seen to be divisible into an inner granular mass (endosarc) and an outer clearer part or envelope (ectosarc); but there is no essential difference in substance between them. Imbedded in the interior granules is a large spherical globule, the nucleus, consisting of a clear chromatic substance containing minute granules of chromatin. A contractile vacuole lies in the ectosarc, and manifests more or less regular and rythmical expansions and contractions; this seems to serve the purpose of an excretory organ. The amœba continually throws out irregular threads and extensions (pseudopods), so that its shape is more often like that of a drop of any thick liquid which has fallen and spattered, than of a globule; this shape is changing incessantly as the creature slowly creeps about. Whenever it touches any edible particle of organic material it slowly enfolds it, and the particle sinks into the body, where it is gradually dissolved, its nutritive material is digested and assimilated, furnishing food and fuel to the protoplasm, and the innutritious parts are finally gathered into the vacuole, whence they are squeezed out and discarded.

Amœba reproduces itself by a simple process of division. A constriction takes place at a point where the nucleus will be divided, and goes on until the animal becomes dumbbell-shaped. Finally the two parts separate, and each becomes a distinct and perfect whole, each with its half of the original nucleus, which at once becomes, in each case, a whole nucleus. After a time these individuals in turn undergo a similar division, and so on. It may therefore be said that amœba never ceases to exist — never dies; but simply multiplies indefinitely by repeated divisions.

Certain forms of *Amœba*, notably *A. coli*, are the cause of a distinct kind of dysentery now termed amœbic dysentery. This is a disease mostly of the tropics, but is also found endemic in the United States. Occasionally the parasite may infect the liver, causing an abscess in that organ. The disease is difficult to treat.

Amor, the god of love among the Romans, equivalent to the Greek Eros. He had no place in the national religion of the Romans, who derived all their knowledge of him from the Greeks. According to the later mythology Amor is the son of Venus and Mars, the most beautiful of all the gods; a winged boy with

bow and arrows, sometimes represented blindfolded. His arrows inflict the wounds of love, and his power is formidable to gods and men. He is not always a playful child in the arms of his mother, but appears sometimes in the bloom of youth, for example, as the lover of Psyche. He is brother of Hymen, the god of marriage, whom he troubles much by his thoughtlessness. According to the earlier mythology he is the oldest of all the gods, and existed before any created being. In English the god of love is less frequently called Amor than Cupid; yet with the ancients *cupido* denoted, properly, only the animal desire.

Amor'go (ancient *Amorgos*), an island in the Grecian Archipelago, one of the eastern Cyclades, 22 miles long, five miles broad; area, 106 square miles; has a town of the same name, with a castle and a large harbor. Pop. 5,000.

Amorites. Though made a separate tribe in the varied and rhetorical lists of the peoples in Canaan ousted by the Israelites, the name is used by Amos in the 8th century as a general term for the primitive inhabitants of Canaan, with attribution of gigantic size and power, as most old nations do with their special aboriginal predecessors. Some critics think, however, that "Canaanite" is used for the peaceful settlers of the plains, and "Amorite" for the warlike tribes on the hills to the north. At any rate, the latter term is always used when hostile tribes are meant. Moses' foes include Sihon and Og the Amorite kings, and Joshua deals with 12 kings of the Amorites west of the Jordan. The Amarna letters show that the coast as far north at least as Sidon was called Kinahi (Canaan), and perhaps the Amorites were the people of the interior; but the usages may be due to the writers coming from different sections.

Amory, Blanche, a shallow, selfish, worldly girl in Thackeray's novel 'Pendennis.'

Amory, Robert, physician: b. Boston 3 May 1842. He graduated at Harvard 1863, M.D. 1866, and studied in Paris and Dublin. He was lecturer at Harvard on the physiological action of drugs 1869; then professor of physiology at Bowdoin Medical College till 1874. Author of 'Bromides of Potassium and Ammonium' (1872); 'Action of Nitrous Oxide' (1870); and important papers on 'Chloral Hydrates,' 'Pathological Action of Prussic Acid,' and 'Photography of the Spectrum'; the volume on 'Poisons' in Wharton & Stillé's 'Medical Jurisprudence'; and 'Electrolysis and Its Applications to Treatment of Disease' (1886).

Amory, Thomas Coffin, lawyer and author: b. Boston 1812; d. there 1889. He graduated at Harvard 1830; and for many years was connected with the municipal government of Boston. Author of 'Life of James Sullivan' (2 vols. 1859); 'Military Services of Maj-Gen. John Sullivan' (1868); 'Life of Sir Isaac Coffin' (1886); 'The Siege of Newport: a Poem' (1888); 'Charles River: a Poem' (1888).

Amos, the prophet: the earliest identifiable Hebrew writer, and the first extant prophet who wrote his prophecies, therefore of great historical importance not only for Hebrew conditions in his age, but for the evolution of their religious thought. He lived under Jeroboam II. of Israel (790–749 B.C.) and Uzziah of Judah at least during part of his career; was in Israel perhaps between 765 and 750, though there are strong reasons for putting him after 745. He was probably a man of position, a fig-planter and cattle-owner (though he calls himself a fig-picker and herdsman) from Tekoa in Judah (see 2 Sam. xiv. 2 for the estimate of its people's astuteness in David's time), near Arabia and the Dedanites; his opportunities for meeting varied human elements had been good, his intellect was vigorous and his nature lofty, and his writings show a singular cultivation and refinement which reminds one how often the Eastern herdsman thus surprises the traveler. He felt that he had a burning moral message to deliver to the Hebrews, and the place to deliver it was in the far more important northern kingdom, then in the flower of its prosperity first and last. Assyria had been greatly weakened by the growth of the kingdom of Urartu (Armenia) to the north, and by internal revolts under Ashur-dan (772–755); meantime it had trampled Damascus into a temporary impotence for aggression. Jeroboam in his long reign was therefore able to win back all that Hazael had taken away, and extend his kingdom from Hamath in Syria down to the Dead Sea: he captured two places in Gilead, and his people thought their military prowess irresistible; they suffered from no raids or tribute, wealth and luxury were increasing rapidly, and self-indulgence with it. As always, laxer foreign religions had come in also: Yahwé was relied on as the national champion, but other gods were worshipped also, and even with him the connection was becoming non-moral, a costly ritual usurping the place of ethical religion. Into this comfortable and boastful population, expecting no attack from Assyria, and with their unhampering religion, came the great moral teacher from the other kingdom, preaching everything most alien and distasteful to them: that their military successes are nothing, and Yahwé will raise up a nation to carry them off beyond Damascus (transplantation, as a means of breaking up rebellious elements and unifying the empire, was introduced by Tiglath-pileser II. of Assyria, 745–727, which suggests the later date for Amos); that Yahwé hates their burnt-offerings and wants nothing but righteousness; that precisely because he is closer to them will he judge them more severely; and that while he will eventually not let the race of Jacob die, he will not restore it till the present kingdom has been obliterated from the earth. This was taking the heart out of the people; and when he came to Bethel, the northern Jerusalem, and reiterated his warnings that Jeroboam would die by the sword and the people be deported, Amaziah the high priest reported him to the king as a public nuisance and conspirator, and contemptuously told him to go back to Judah and prophesy to such as would pay him, but not to do it in Bethel, for it was the king's. This brought out the invaluable autobiographic fragment (vii. 14–15), wherein he tells us of his position, and that he is none of the guild of professional prophets and does not need to take fees for his utterances, but a private individual with a call from God to go out and tell the truth. For him, indeed, it is correct to say God and not Yahwé: he is an ethical

monotheist. His writings as they stand show signs of change and interpolation from subsequent hands; but the undoubtedly authentic part exhibits fine literary as well as intellectual and spiritual qualities, and the imagery is graphic and certifies to his pastoral and agricultural employment. (A special work on Amos is by H. G. Mitchell, Boston, 1889.)

Amphib'ia, a class of back-boned creeping animals comprising the newts, frogs, and toads, together with several extinct groups, which is classified between the fishes and the reptiles. The most prominent characteristic is indicated by the name, which refers to the fact that these animals are provided with a respiratory apparatus which enables them to breathe both water and air. It is not meant, however, that the *Amphibia* are able to breathe in either air or water at the same time, but that the young are provided with gills and live in water up to a certain age, or in rare cases permanently, after which they acquire lungs and thereafter breathe atmospheric air. As these young as a rule are different from their parents and must undergo metamorphosis from the larval into the adult condition, amphibians as a class are usually said to undergo metamorphosis, but this is equally true of some fishes and it is not true of all amphibians. The evidence not only of modern similarity of structure, but that obtained from a study of the fossil forms, makes it plain that the *Amphibia* are the result of the evolution of a branch from an ancient fish-stock, probably by way of the lung-fishes or *Dipnoi* (q.v.). On the other hand they are related in a not very different degree to the reptiles. The connection link according to Gadow, is formed by the *Stegocephali;* all the recent orders are far too specialized. The line leading from *Stegocephali* to fossil reptiles is extremely gradual, and the same consideration applies to the line which leads downward to the fishes; but the great gulf within the *Vertebrata* lies between fishes and amphibians, that is, between absolutely aquatic creatures with internal gills and fins, and terrestrial four-footed creatures with lungs and fingers and toes. No great phylogenetic importance attaches to the possession of external gills, as it is not unlikely that in the *Amphibia* these organs owe their origin to entirely larval requirements.

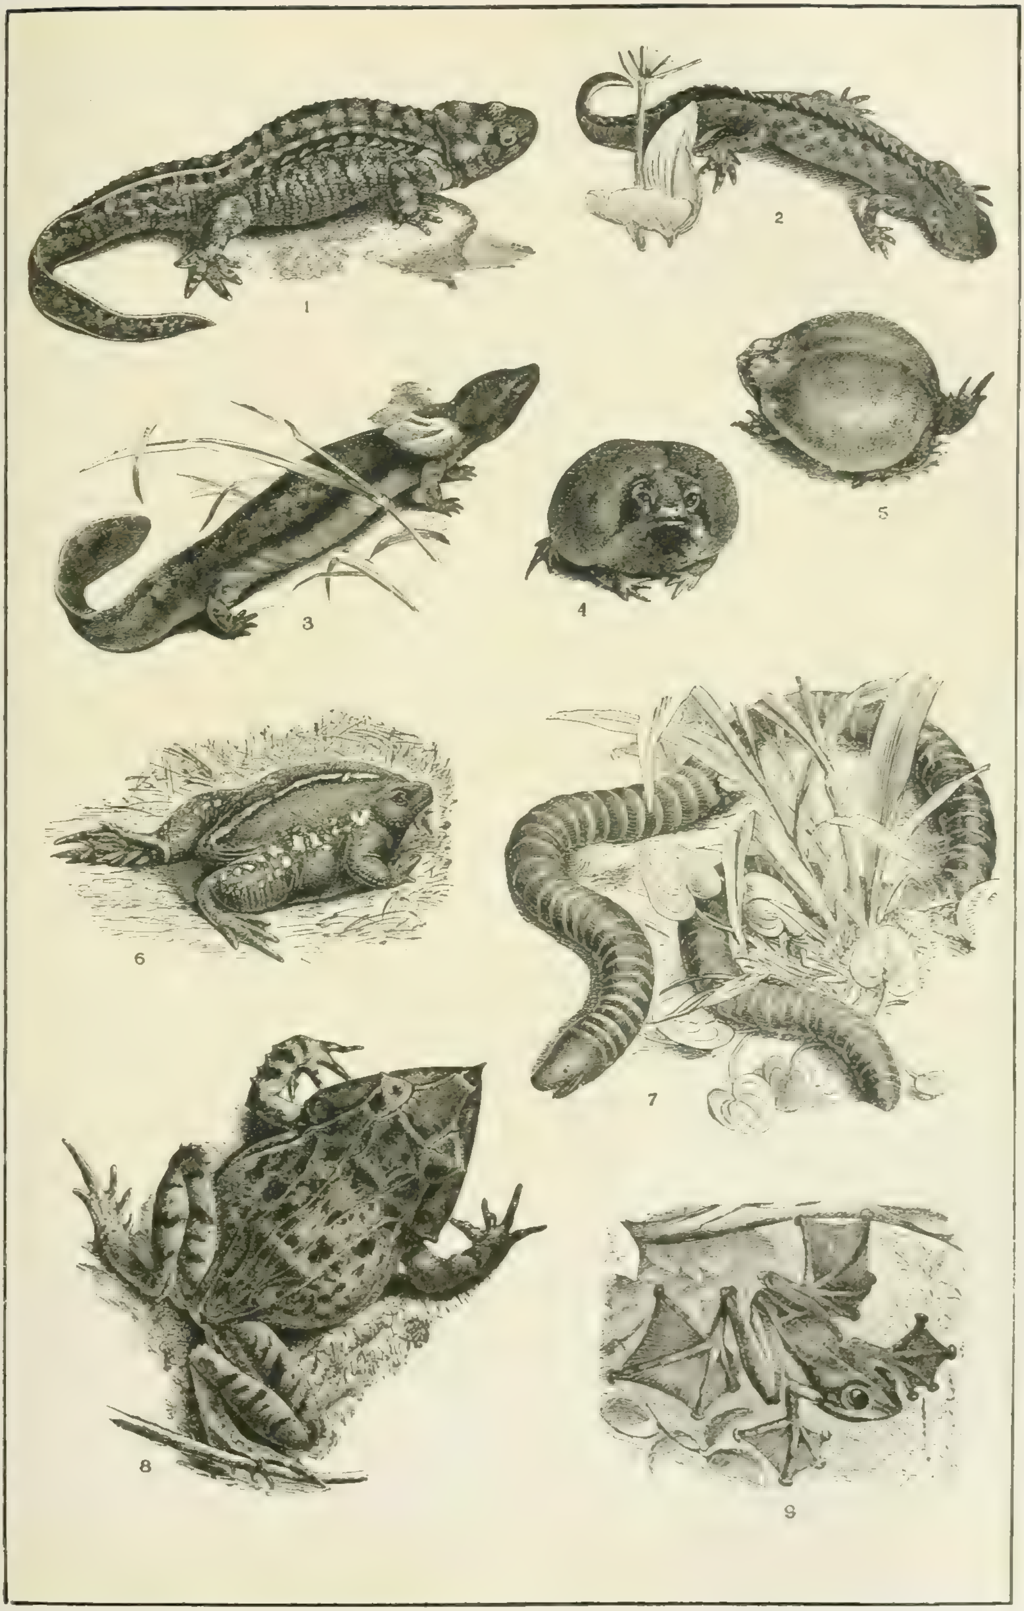
Although in the Palæozoic age the great stegocephalous amphibians (more usually called labyrinthodonts, q.v.), flourished as the only terrestrial vertebrates of importance, the class never attained a dominant position. Intermediate between the aquatic fishes and the gradually rising terrestrial reptiles, the amphibians were pushed aside in a double way by the struggle of evolution, until now most of them have become extinct. The remainder persist only because they have found shelter in the nooks and corners of the world to which they have become adapted by small size and aquatic habits; and only one group, the frogs and toads, fortunate in their plasticity, have spread over the whole globe and exhibit some richness in forms.

The class *Amphibia* is divided into two subclasses: (1) *Stegocephali* (q.v.), which is wholly extinct; (2) *Lissamphibia*, which includes all of the modern forms, contained in three orders: (1) *Apoda,* composed of the family *Cæcilliidæ* (see CÆCILLIANS); (2) *Urodela,* including the long-tailed, smooth-skinned, aquatic salamanders, newts, mud-puppies, and the like; (3) *Anura,* comprising the tailless forms, or frogs and toads, of which there are two divisions,— the few *Aglossa,* which have no tongue, and the tongue-bearing *Phaneroglossa,* which includes the great majority of forms.

Fossil Amphibia. The modern frogs and salamanders are a small and scanty remnant of the *Amphibia* of Palæzoic time. During the Carboniferous and Permian periods they were the dominant form of life and of great variety in form, including some of very large size, 12 feet or more in length. All these ancient *Amphibia* belong to an extinct group, the *Labyrinthodonta* (sometimes called *Stegocephalia*), or "armored amphibians," distinguished by having the wide flat head completely roofed over with bone, and the body more or less armored with bony plates and scales. The skull has two openings for the eyes, two at the front margin for the nostrils, and a single one in the middle for the pineal eye. Like modern amphibians, they breathed by gills when young, but by lungs when adult. All had long tails and most of them short stout legs. Some were elongated and snake-like, others tadpole-like with large heads shaped like a broad arrow (*Diplocaulus*) and no limbs; others, and these the largest, heavy-bodied, with flat conical or semi-circular heads, short legs, and five-toed feet (*Labyrinthodon, Eryops*).

These ancient amphibians illustrate various stages in the evolution of the backbone of modern *Vertebrata* from the notochord or segmented rod of cartilage from which it was derived. In the smaller and more primitive types the segments of cartilage are but slightly ossified in a number of separate plates or incomplete rings of bone. In others each vertebra is composed of two or four pieces, which remain separate during life instead of consolidating into a single bone, as in modern vertebrates. In others, again, the vertebra is completely united. The oldest known labyrinthodonts are from the Carboniferous rocks, and are related to some of the older Palæozoic dipnoan fishes, from which they may have been descended. In the Permian they attained large size and great abundance, and continued into the Triassic period, by the end of which they had become extinct. Their foot-tracks, often preserved in muddy sandstones of these periods, are sometimes curiously like the impressions of a human hand, whence they received the name of *Cheirotherium,* or "beast-with-a-hand," before their nature was recognized. The frogs and salamanders are probably descended from primitive labyrinthodonts, but are very little known as fossils. One fossil species, allied to the giant salamander of Japan, was found in the Miocene strata of Oeningen many years ago (1726) and was supposed by an early naturalist to be the fossil skeleton of a man, and described as "*homo diluvii testis et theoscopos*"— the man who was witness to the Deluge and saw God — a quaint reminder of the geological speculations of two centuries ago.

Consult Gadow, 'Amphibia and Reptiles' (London, 1901); Boulenger, 'Catalogue of Batrachia' in British Museum (London, 1882); and many papers in English scientific periodicals; Cope, 'Batrachia of North America.'



1. A Spanish Salamander (Pleurodires waltli).
2. European Crested Newt (Triton cristatus).
3. Menobranch (Necturus maculatus).
4-5. East African Toad (Breviceps mossambicus).
6. A Mexican Toad (Rhinophrynus dorsalis).
7. An Amphisbæna (Siphonops annulatus).
8. Horned Frog (Ceratobatrachus Guentheri).
9. Flying Frog (Rhacophorus pardalis).

Amphibole, am'fi-bōl (from the Greek *amphibolos,* "doubtful," in allusion to the difficulty of distinguishing it from pyroxene). In mineralogy, (1) a common mineral, crystallizing in the monoclinic system, and varying greatly in chemical composition. The name was first given by Haüy in 1801 as distinguishing a species of which he regarded hornblende and actinolite as varieties. In 1809 he included tremolite also. In general, the species may be described as a normal metasilicate of calcium and magnesium, associated with iron, manganese, sodium, potassium, and hydrogen.

(2) *Amphibole group.*— An important group of minerals, including the species described above, and taking its name therefrom. Its constituent species are widely different in chemical composition, and are closely allied to the members of the pyroxene group. All the species of the amphibole group have a prismatic cleavage of from 54° to 56°, and they also exhibit close relationships in the optical properties. All the species of the pyroxene group have a fundamental prism with an angle of 93° and 87°, the corresponding angle in amphibole being 56° and 124°. The specific gravity of the pyroxenes is usually higher than that of the species of the amphiboles with which they are likely to be confused. Alkalis are met with more commonly in the amphiboles, and magnesium is also more prominent in that group. The amphibole group is divided into three main sections according to the crystalline forms of its species. Dana's classification is as follows:

A. Orthorhombic Section.
- Anthophyllite.
- (Gedrite.)

B. Monoclinic Section.
- Amphibole:
  - *Non-aluminous varieties*:
    - Tremolite.
    - Actinolite.
    - Cummingtonite.
    - Dannemorite.
    - Grünerite.
    - Richterite.
  - *Aluminous varieties*:
    - Edenite.
    - Pargasite.
    - Hornblende.
- Glaucophane.
- Riebeckite.
- Crocidolite.
- Arfvedsonite.
- (Barkevikite.)

C. Triclinic Section.
- Ænigmatite.

Amphibol'ogy, an equivocal phrase or sentence, not from the double sense of any of the words, but from its admitting a double construction, as "The duke yet lives that Henry shall depose." The word *that* may be ambiguous, and consequently the sentence is an example of equivocation, not amphibology.

Amphic'tyon'ic League or **Council,** in ancient Greece, an assembly composed of deputies from 12 Greek tribes, each of which sent two deputies, who assembled with great solemnity; composed the public dissensions, and the quarrels of individual cities, by force or persuasion; punished civil and criminal offenses, and particularly transgressions of the law of nations and violations of the temple of Delphi. After the decision was published a fine was inflicted on the guilty state, which if not paid in due time was doubled. If the state did not then submit, the whole confederacy took arms to reduce it to obedience. The assembly had also the right of excluding it from the confederation. An instance of the exercise of this right gave rise to the Phocian war, which continued 10 years (B.C. 355–346).

Amphic'yon, a genus of extinct mammals, found fossil in Miocene rocks, which is usually placed among the extinct *Canidæ* (dogs), but has many bear-like features, such as plantigrade, five-toed feet, and the structure of the ulna and radius. The largest species was about the size of a bear, but with a very dog-like head. It belonged to the Old World, but a closely allied American Miocene form is *Daphænus.*

Am'phineu'ra. See Mollusks.

Amphi'on, in Greek mythology, son of Zeus and Antiope, his twin brother being Zethus. He is represented as being the oldest of the Grecian musicians. In Lydia, where he maried Niobe, the daughter of King Tantalus, he learned music, and brought it thence into Greece. He reigned in Thebes, which he partly built, and it is said that at the sound of his lyre the stones voluntarily formed themselves into walls; also that wild beasts, and even trees, rocks, and streams followed the musician. With the aid of his brother Zethus he is said to have avenged Antiope, who had been imprisoned and ill-used by his father, and to have bound Dirce, his stepmother, to the horns of a wild bull. This incident is supposed to be represented by the famous piece of sculpture, the Farnese bull, in the Farnese Palace at Rome.

Am'phiox'us, the lancelet, a small animal of the marine class *Leptocardii.* Its earliest scientific name is *Branchiostoma.* From its somewhat worm-like form it was for a long time regarded as a worm by some authors, and originally as a mollusk (*Limax*) by Pallas. It is now named *Amphioxus lanceolatus;* lives buried in the sand just below low-water mark, the head or "oral hood" projecting above into the water. It also swims in a vertical or upright position, also frequently lying on one side on the sand; and burrows head foremost rapidly downward in the sand. It extends along our coast from the mouth of Chesapeake Bay to Florida; also on the eastern coast of South America and in the north European seas, the Mediterranean, the East Indies and Australasia, the species being truly cosmopolitan. Another very closely allied genus, *Asymmetron,* includes two species, one of which occurs at the Bahamas, and the other in the Louisade Archipelago, southeast of New Guinea.

The body of *Amphioxus* is about two inches in length, slender, compressed, pointed at each end, hence the generic name (*Amphioxus, ἀμφί* both, *ὀξύς,* sharp), the head-end being thin and compressed. The muscular segments are distinct to the naked eye. From the mouth to the vent is a deep ventral furrow, and a slight dorsal fin extends along the back and beneath as far front as the vent, forming the ventral fin, while the wider portion at the tail is the caudal fin. The oral hood has a large median external opening, which is oral, surrounded with a circle of ciliated tentacles supported by semi-cartilaginous processes arising from a circumoral ring. At the bottom of this opening is the mouth which leads directly into a large

broad pharynx or "bronchial sac," protected at the entrance by a number of minute ciliated lobes. The walls of this sac are perforated by long ciliated slits, of which there are more than a hundred pairs, comparable with those of the bronchial sacs of ascidians and of *Balanoglossus*. The water which enters the mouth passes out through these slits, where it oxygenates the blood and enters the peribranchial cavity, thence passing out of the body through the abdominal pore (atriopore). The pharynx leads to the stomach with which is connected the liver or cœcum. There is a system of blood-vessels, but no heart. A contractile median vessel, the ventral aorta, beginning at the free end of the liver, and extending along the underside of the pharynx, sends branches to the sac and two anterior branches to the dorsal aorta. On the dorsal side of the pharynx the blood is poured by the two anterior trunks, and by the branchial veins which carry away the aërated blood from the branchial bars, into a great longitudinal trunk or median dorsal aorta, by which it is distributed throughout the body. There are also vessels distributed to the liver, and returning vessels, representing the portal and hepatic veins. The blood-corpuscles are white and nucleated.

The vertebral column of the true vertebrates is represented in the lancelet by a notochord, a long, flexible, cylindrical rod pointed at both ends, which extends to the end of the head far in front of the nervous cord; and also by a series of semi-cartilaginous bodies above the nervous system, and which are thought to represent either neural spines or fin-rays. The nervous cord is a rod-like structure which lies over the notochord. It is not divided into a true brain and spinal cord, though the cord is slightly enlarged at the anterior end, where a rudimentary ventricle is said to exist. The nerve-cord sends off a few nerves to the periphery, with a nerve to the single minute median eye. An olfactory pit opens externally on the left side of the snout. The principal excretory organs are about ninety pairs of peculiarly modified nephridia, situated above the pharynx, and in relation with the main cœlomic cavities. The reproductive glands are square masses or pouches, of which there are about 26 pairs attached in a row on each of the walls of the body-cavity. The individuals may be male or female, the only sexual differences being in the reproductive glands.

The eggs may pass out of the mouth or through the pore. Kowalevsky found them issuing in May from the mouth of the female, and fertilized by spermatic particles, likewise issuing from the mouth of the male. The eggs are very small, 0.105 millimetres in diameter. The eggs undergo total segmentation, leaving a segmentation cavity. The body-cavity is next formed by invagination. The blastoderm now invaginates and the embyro swims about as a ciliated gastrula. The body is oval, and the germ does not differ much in appearance from a worm, starfish, or ascidian in the same stage of growth. No vertebrate features are developed. Soon the lively, ciliated gastrula elongates, the alimentary tube arises from the primitive gastrula cavity, while the edges of the flattened side of the body grow up as ridges, which afterward, as in all vertebrate embryos, grow over and enclose the spinal cord. When the germ is 24 hours old it assumes the form of a ciliated flattened cylinder, and now resembles an ascidian embryo, there being a nerve cavity with an external opening, which afterward closes. The notochord appears at this time. In the next stage observed the adult characters have appeared, the mouth is formed, the first pair of gill-openings are seen, 11 additional pairs appearing. It thus appears that while the lancelet at one time in its life presents ascidian features, yet, as Balfour states, "all the modes of development found in the higher vertebrates are to be looked upon as modifications of that of Amphioxus."

A. S. PACKARD,
Late Prof. Zoology, Brown University.

Amphip'oda, an order of Crustacea, in which the body is compressed and usually arched. There is no carapace or distinct cephalothorax, but a small head, bearing two pairs of antennæ, a pair of jaws (mandibles), and three pairs of maxillæ. The thoracic segments are separate and like those of the abdomen, not being fused and united with the head segments. Respiration is performed by lamellate or leaf-like gills arising from the middle pair of legs. The amphipods are represented by the common beach-flea or beach- or sand-hopper (*Orchestia agilis*); by Gammarus, or "scud," species of which live both in the sea and in fresh-water. Extreme forms are the ghost-like or skeleton-like attenuated *Caprella*, abounding in eel-grass below low tide; and which in walking loop the body somewhat like a geometricid caterpillar. Another form is *Chelura terebrans*, which burrows in wood, in company with the gribble. It is very active and frequently destructive to submerged piles. Other forms are eyeless and live in caves or dark wells.

Amphipolis, an important city of Thrace or Macedonia; at the mouth of the Strymon River, 33 miles from the Ægean. It was founded by an Athenian colony about 436 B.C.; was captured by Sparta in 424 B.C.; and near it the Spartans defeated the Athenians in 422 B.C. Subsequently it became a Macedonian possession; was called Popolia in the Middle Ages; and its site is now occupied by the Turkish town of Yenikeui.

Am'phisbæ'na, one of the degraded worm-shaped lizards of the family *Amphisbœnidœ*, which lead an entirely subterranean life, burrowing like earth-worms. They have a soft skin forming numerous rings and containing only vestiges of scales except upon the head. External limbs are absent (except in one genus), but only vestiges remain of any limb-bones. Their tails are so short and blunt that they are popularly said in some countries to have two heads, whence the scientific name of the group. This notion is strengthened by their ability to move either forward or backward with equal ease. About a dozen genera and more than 60 species are known, most of which inhabit the warmer parts of America and Africa; some also live in Asia Minor and in Spain. They are frequently found in ants' nests, and have been called "mothers of ants" in consequence. Their eyes and ears are concealed beneath the skin. A common species in South America and the West Indies (*Amphisbœna fuliginosa*) is checkered black and white, and is from one to two feet in length. Like the others it feeds

upon worms and small insects found under the surface of the ground. They are quite harmless.

Am'phithe'atre, with the Romans, a building without a roof, of a round or oval form, destined for the combats of gladiators or of wild beasts. In the middle was the arena, a large place covered with sand, on which the fights were exhibited. Round about were the vaults or caves in which the animals were kept; above these was the gallery, from which ascended successive rows of seats, each of greater height and circumference than the preceding. The first 14 were for the senators and judges, the others for the common people. Julius Cæsar erected the first large amphitheatre at Rome for his gladiatorial exhibitions. It was of wood. Statilius Taurus, 20 years later, built the first stone one. The Coliseum at Rome is the largest of all the ancient amphitheatres. (See COLISEUM.) In Verona there is one the interior of which still shows the whole ancient architecture and is carefully preserved.

Am'phitri'te, in Greek mythology, a daughter of Oceanus and Tethys, or of Nereus and Doris. Poseidon wished to make her his wife, and as she hid herself from him he sent a dolphin to find her, which brought her to him, and received as a reward a place among the stars. As a goddess and queen of the sea she is represented as drawn in a chariot of shells by tritons, or riding on a dolphin, before which a cupid swims, with the trident of Poseidon in her hand.

Amphit'ryon, in Greek mythology, king of Thebes, son of Alcæus, and husband of Alcmena. Plautus, and after him Molière, have made the trick played upon him by Zeus (in assuming his form in order to enjoy the embraces of his wife) the subject of amusing comedies, in which the return of the true Amphitryon, and his meeting with the false one, occasion several humorous scenes.

Am'phiu'ma, a genus of Amphibians that lose their tadpole gills, but retain a gill slit. See KONGO SNAKE.

Am'phora, a vessel used by the Greeks and Romans for holding various liquids, particularly wine. They were of various forms, but most commonly tall and narrow, with a pointed end which fitted into a hole or socket to enable them to stand upright. Properly an amphora was a two-handled vessel, from Greek *amphi*, both, and *phero*, to carry.

Amphoteric, a chemical property of many organic substances, urine, milk, blood, etc., to show acid to blue litmus and alkaline to red litmus, thus paradoxically being both acid and alkaline.

Am'plitude, in astronomy, the distance of any celestial body or other object (when referred by a secondary circle to the horizon) from the east or west points; the complement to the amplitude, or the distance from the north or south point, is called the azimuth.

Ampudia, Pedro de, Mexican soldier. He first appears in the wars against Texas, Santa Anna (q.v.) making him a general in 1840. He engaged in forays and fights here for some years, coming into conflict with Summerville's Texas troops and commanding the land forces in the siege of Campeachy; compelled to retreat 26 June 1843, he went to Tabasco, and in 1844 captured and summarily executed Sentmanat who had assaulted it. The act was loudly condemned, and he was dismissed. He reappeared in the United States-Mexican war under Arista; was in the fight at Matamoras, 11 April 1846; was given command of Monterey, but surrendered to Taylor 24 September and vanishes from history.

Ampul'la (Lat.), in antiquity, a vessel bellying out like a jug, that contained unguents for the bath; also a vessel for drinking at table. The ampulla has also been employed for ceremonial purposes, such as holding the oil or chrism used in various church rites and for anointing monarchs at their coronation.

Ampullaria. See APPLE-SHELL.

Am'puta'tion. See SURGERY.

Amraphel, king of Shinar (= Sumer, the Sumerian or South Babylonian plain), a monarch mentioned in Gen. xiv. as an ally of Chedorlaomer, king of Elam, in subduing his revolted Palestinian vassals. Two other allied kings are named: Arioch of Ellasar (Larsa, South Babylonia) and Tidal of Goiim (translated "nations" in Authorized Version; identified by some with Gutium in Media, by others with "the tribes" = the wandering Kurds). Neither of the names nor any mention of the raid is found on the inscriptions; and the expedition, with its capture of Lot and the successful recapture by Abraham, has no critical standing. Nevertheless it is most interesting historically; for the non-Jewish names are apparently genuine, and the conditions are precisely those of the times which the names would imply. Arioch would correspond to the Babylonian Eriaku, supposed to be found in a fragmentary epic on the invasion of Babylonia; Tid'al to a Tudhkula or Tudhghula also said to be recognizable there; and Chedorlaomer to Kudur-Laghamar, the first half of which is found in other Elamite royal names, as Kudur-Mabuk, etc., and the last is probable. As to Amraphel, he is very plausibly Hammurabi (q.v.), the great revivor of the Babylonian monarchy about 2250, after its conquest by the Elamites; or rather Hammurabi-ilu (the divine name el or ilu added, as common in Babylonian and Egyptian: cf. Joseph-el and Jacob-el against the Hebrew Joseph and Jacob), or perhaps Hammu-rapaltu, a probably dialectic variant of Kimta-rapashtu actually found written. Chedorlaomer's expedition is like other known ones of Babylonian kings against the lands west to the Mediterranean, which they claimed as tributary. But there is a closer verisimilitude, which makes it practically certain that the substance of the story was taken from a Babylonian tablet describing an actual occurrence: Amraphel in the story is a subordinate ally of Chedorlaomer, and the historical Hammurabi was apparently a dependent sub-king of Babylon under the Elamites before he threw off their yoke. The added Abraham story may represent a tradition welded with the other in later times.

Amritsir, ŭm-rĭt'săr, or **Umritsir** (that is, "the pool of immortality"), a town of Hindustan, capital of a district of the same name, in

the Panjab, the principal place of the religious worship of the Sikhs. It is, on account of its favorable situation between Cabul and Delhi, Cashmere, and the Deccan, a place of great trade, and has considerable manufactures of shawls and silks; but its chief attraction to the natives is the sacred pond constructed by Ram Das (one of the earlier pontiffs of the Sikh faith), in which the Sikhs immerse themselves that they may be purified from all sin. This holy basin is 150 paces square, built of brick, having in its centre the chief temple of the Sikh religion. Under a silken canopy in this temple is deposited the book of Sikh religion and laws, called the Granth. The voluntary contributions of pilgrims and devotees support this place, to which 600 priests are attached. Pop. (1901) 164,000 (including cantonments).

The district of Amritsir lies between the rivers Ravi and Bias. It is intersected by numerous canals. Its area is 1,601 miles. Pop. (1902) 2,500,000.

Am'ru, originally an opponent, and subsequently a zealous supporter of Mohammed, and one of the ablest of the Mohammedan warriors. He brought Egypt under the power of the Caliph Omar in 638, and governed it wisely till his death in 663. The burning of the famous Alexandrian Library has been generally attributed to him, though only on the authority of a writer who lived six centuries later.

Amsdorf, Nicolaus, a Protestant reformer of the 16th century: b. in Gross-Zschopa, near Wurzen, on the Mulde, 3 Dec. 1483; d. 14 May 1565. He was educated at Leipsic, and then at Wittenberg, where he was one of the first who matriculated (1502) in the recently-founded university. He obtained various academical honors, and became professor of theology in 1511. He joined Luther at the very beginning of his struggle (1517); continued all along one of his most determined supporters; was with him at the Leipsic Conference and the Diet of Worms; and was in the secret of his Wartburg seclusion. He assisted the first efforts of the Reformation at Magdeburg, at Goslar, and at Einbeck; took an active part in the debates at Schmalkald, where he defended the use of the sacrament by the unbelieving; and spoke out strongly against the bigamy of the Elector of Hesse. He urged the separation of the High Lutheran party from Melancthon, got the Saxon dukes to oppose the Frankfurt Recess (1558), and continued to fight for the purity of Lutheran doctrine until his death.

Amsler, Samuel, one of the most distinguished of engravers: b. in Schinznach, in the canton of Aargau, 1791; d. 18 May 1849. Amsler's principal engravings are 'The Triumphal March of Alexander the Great' and a full-length 'Christ,' after the sculptures of Thorwaldsen and Dannecker; the 'Burial of Christ,' and two 'Madonnas,' after the pictures of Raphael; and the 'Triumph of Religion in the Arts,' after Overbeck, his last work, on which he spent six years.

Amsterdam, formerly called **Amstelredam**, the capital of the Netherlands, is situated in the province of North Holland, at the influx of the Amstel to the Ij or Y (pronounced eye), an arm of the Zuyder Zee. The city is built in the shape of a semi-circle, and within this semicircle four canals — the Prinsen Gracht, Keizer's Gracht, Heeren Gracht, and the Singel — extend in the form of polygonal crescents, nearly parallel to each other, while numerous smaller canals intersect the city in every direction, dividing it into about 90 islands, with about 300 bridges. The site of Amsterdam was originally a peat bog, and all its buildings rest upon piles that are driven some 40 or 50 feet through a mass of loose sand and mud until they reach a solid stratum of firm clay. This foundation is perfectly secure as long as the piles remain under water. At the beginning of the 13th century it was merely a fishing village, with a small castle, the residence of the lords of Amstel. In 1296, on account of its share in the murder of Count Floris of Holland, the rising town was demolished; but in 1311, with Amstelland (the district on the banks of the Amstel), it was taken under the protection of the Counts of Holland, and from them received several privileges which contributed to its subsequent prosperity. In 1482 it was walled and fortified. After the revolt of the seven provinces (1566) it speedily rose to be their first commercial city and a great asylum for the Flemish Protestants; and in 1585 it was considerably enlarged by the building of the new town on the west. The establishment of the Dutch East India Company (1602) did much to forward the well-being of Amsterdam, which, 20 years later, had 100,000 inhabitants. In the middle of that century the war with England so far reduced the commerce of the port that, in 1653, 4,000 houses stood uninhabited. Amsterdam had to surrender to the Prussians in 1787, to the French in 1795; and the union of Holland with France in 1810 entirely destroyed its foreign trade, while the excise and other new regulations impoverished its inland resources. The old firms, however, lived through the time of difficulty, and in 1815 commerce again began to expand — an expansion greatly promoted by the opening in 1876 of a new and more direct waterway between the North Sea and the city.

The city has a fine appearance when seen from the harbor or from the high bridge over the Amstel. Church towers and spires, and a perfect forest of masts, relieve the flatness of the prospect. The old ramparts have been leveled, planted with trees, and formed into promenades. Between 1866 and 1876 many spacious streets and an extensive public park were added to the city. Tramways have been successfully introduced, and the harbor greatly improved. There is railway communication with all parts of the country and of Europe. Rich grassy meadows surround the city. On the west side are a great number of windmills for grinding corn and sawing wood. On each side of the three chief canals, with a row of trees and a carriage-way intervening, are handsome residences. The building material is brick; and the houses have their gables toward the streets, which gives them a picturesque appearance. The defenses of Amsterdam now consist in a row of detached forts, and in the sluices, several miles distant from the city, which can flood in a few hours the surrounding land. A hard frost, however, like that of 1794–5, when Pichegru invaded the country, would render this means of defense useless.

The population, which from 217,024 in 1704, sank to 180,179 in 1815, rose steadily to 503,285 in 1897, of whom the majority belong to the

Dutch Reformed Church. Of the remainder, about 80,000 were Catholics, 30,000 German Jews, and 3,200 Portuguese Jews. The chief industrial establishments are sugar refineries, engineering works, mills for polishing diamonds and other precious stones, dockyards, manufactories of sails, ropes, tobacco, silks, gold and silver plate and jewelry, colors, and chemicals, breweries, distilleries, with export houses for corn and colonial produce; cotton-spinning, book-printing, and type-founding are also carried on. The present Bank of the Netherlands dates from 1824, Amsterdam's famous bank of 1609 having been dissolved in 1796.

The former Stadhuis ("townhouse"), converted in 1808 into a palace for King Louis Bonaparte, and still retained by the reigning family, is a noble structure. Built by Van Kampen in 1648–55, and raised upon 13,659 piles, it extends 282 feet in length by 235 feet in breadth, and is surmounted by a round tower rising 182 feet from the base. It has a hall 120 feet long, 57 wide, and 90 high, lined with white Italian marble — an apartment of great splendor. The cruciform *Nieuwe Kerk* (New Church), a Gothic edifice of 1408–14, is the finest ecclesiastical structure in the city, with a splendidly carved pulpit, and the tombs of Admiral de Ruyter, the great Dutch poet Vondel, and various other worthies. The Old Church (*Oude Kerk*), built in the 14th century, is rich in painted glass, has a grand organ, and contains several monuments of naval heroes. Literature and science are represented by a university supported by the municipality (till 1876 known as the *Athenæum Illustre*), by academies of arts and sciences, by museums and picture galleries, a palace of national industry, a botanical garden, several theatres, etc. The new Ryksmuseum contains a truly national collection of paintings, its choicest treasure being Rembrandt's 'Night-guard.' Rembrandt (q.v.) made Amsterdam his home; and his statue (1852) now fronts the house he occupied. Spinoza was a native. The hospital for aged people, the poorhouse, house of correction, the orphan asylums, a navigation school, and many benevolent societies, are well supported and managed on good principles. A water supply was introduced in 1853. The North Holland Canal, to which Amsterdam is so largely indebted for the rapid increase of its commerce, is noticed under Zuider Zee. Pop. (1891) 417,539.

Amsterdam, N. Y., a city of Montgomery County, 33 miles northwest of Albany. It is located on the Mohawk River, the Erie Canal, and the West Shore railway, and is a busy manufacturing centre.

Industries, etc.— Amsterdam has about half a hundred factories, among the numerous products being such diversified objects as carpets, knit-goods, rugs, wagon-springs, paper, silk, paper-boxes, and brooms. There are also foundries and machine-shops; three daily newspapers are published.

Public Institutions, Buildings, etc.— Here are located an academy, a hospital, a board of trade, numerous churches, and a Roman Catholic institute. There are well-paved streets, a fine system of drainage, an excellent water supply, and an electric lighting system.

History.— Amsterdam was first settled about 1778, and until 1804 it was known as Veedersburg. It was incorporated as a village in 1830, and as a city in 1885. Pop. (1890) 17,336; (1900) 20,929; (1905) 23,943.

Amu, Amoo, Amoo Darya (Arab. *Gihon*), a river of Central Asia, the ancient Oxus. It takes its rise in the eastern Pamir, near the boundary of eastern Turkestan, flows at first generally west (to lon. 66° E.), thence generally northwest, and empties by a delta into the southern part of the Aral Sea. It receives several affluents from the mountains of Turkestan and the Hindoo Koosh. About 1,600 miles in length, it is navigable by light draught vessels for about 800. As a means of irrigation, it is of considerable importance.

Amulet, a piece of stone, metal, or other substance, marked with certain figures or characters, which people wear about them as a protection against diseases and enchantments. The name, as well as the thing itself, is derived from the East. The word comes from the Arabic *hamalah* (anything hung round the neck). Among the Turks, and many people of central Asia, every individual thinks an amulet necessary to secure him from harm. They were introduced into Christian Europe by the Jews. With the ancients, for example, the Egyptians, Greeks, Romans, they were frequently found. From the pagans they were introduced among the Basilidians. Their amulets were stones with the word *Abraxas* engraved on them. The Jews had many superstitious notions about amulets. Many Christians of the 1st century wore amulets which were marked with a fish as a symbol of the Redeemer. To the Christian divines the use of amulets was interdicted by the Council of Laodicea under penalty of dismissal from office. With the spread of Arabian science and astrology the astrological amulets of the Arabians, the talismans, came into use in the West. The Turks, the Chinese, the people of Thibet, and many other nations, have yet great confidence in them. See Superstition; Talisman.

Amur, am-ör', a river formed by the junction (about lat. 53° N. and lon. 121° E.) of the Shilka and the Argun, which both come from the southwest. From the junction the river flows first southeast and then northeast, and, after a total course of 3,060 miles, falls into the Sea of Okhotsk opposite the island of Sakhalin. It is very valuable for navigation, and carries a considerable fleet of steamers, but on account of the bar at its mouth goods are generally disembarked and carried overland to Alexandrovsk.

In 1636 Russian adventurers made excursions to the lower Amur, and in 1666 built stations and a fort at Albazin. In 1685 both stations and the fort were taken by the Chinese, but were promptly retaken by the Russians, who in 1689 abandoned the whole territory of the Amur to the Chinese.

In 1854–6 two military expeditions were conducted by Count Muravieff, who established the stations of Alexandrovsk and Nikolaevsk. In 1858 China agreed to the Treaty of Tientsin, by which the boundaries of Russia and China were defined. The left bank of the Amur and all the territory north of it became Russian; and below the confluence of the Ussuri both banks. In 1860, after the occupation of

Pekin by the British and French, General Ignatieff secured the signature of Prince Kung to a treaty by which Russia acquired the broad and wide territory comprised between the river Amur and the mouth of the Tumên, extending 10° of latitude nearer the temperate regions, and running from the shore of the north Pacific eastward to the banks of the river Ussuri, a principal affluent of the Amur. In September 1900 Russia took formal possession of the right bank of the river.

This vast territory falls into two Russian provinces — the Maritime Province between the Ussuri and the sea, and the government of Amur north of the river. The latter has an area of 175,000 square miles. The country is richly timbered, and is admirably adapted for pasturage and agriculture, though the climate is severe. Fur-bearing animals are still plentiful, and the river abounds in fish. The capital is Khabarovka. Nikolaevsk, once the only important place in these regions, is on the Amur, 26 miles from its mouth, where the river is 1¼ miles wide, and in places 15 feet deep; but the political centre tends southward to the more temperate Maritime Province (area, 730,000 square miles), near the southern end of which is situated the important harbor of Vladivostok ("Rule of the East"), or Port May, which in 1872 was placed in telegraphic communication with Europe by the China submarine cable, and is now the capital of the Amur provinces. The island of Sakhalin (Saghalien), north of the Japan group, along a portion of the coast of Asiatic Russia, and formerly possessed partly by Russia and partly by Japan, is also a part of the Amur region in the wider sense.

Amurath I., ä'mōō-rät, a sultan of the Turks; succeeded his father Orchan in 1360. He founded the corps of Janissaries, conquered Phrygia, and on the plains of Cassova defeated the Christians. In this battle he was wounded, and died the next day, 1389.

Amurath II., one of the more illustrious of the Ottoman emperors, succeeded his father, Mohammed I., in 1421, at the age of 17. In 1423 he took Thessalonica from the Venetians; in 1435 subdued the despot of Servia, besieged Belgrade, which was successfully defended by John Hunniades; defeated the Hungarians at Varna in 1444, and slew their king, Ladislaus. He died in 1451.

Amurath III., succeeded his father, Selim II., in 1574. His first act was the murder of his five brothers. He added several of the best provinces of Persia to the Turkish empire. He was noted for his avarice, and his sensual excesses made him prematurely old. He died in 1595.

Amurath IV., succeeded his uncle, Mustapha X., 1623. After two unsuccessful attempts he took Bagdad from the Persians in 1638, and ordered the massacre of 30,000 prisoners who had surrendered at discretion. The excessive cruelty and debauchery of Amurath IV. have earned for him the character of being one of the worst sovereigns that ever reigned over the Ottomans. He died in 1640.

Amurath V., Sultan of Turkey: b. 21 Sept. 1840, and succeeded to the throne in 1876 as the result of a revolution that caused the overthrow of his uncle Abdul Aziz His reign was for a few months only, as he developed strong symptoms of insanity and was deposed in August 1876.

Amyclæ. (1) An ancient town of Laconia, on the eastern bank of the Eurotas, 2½ miles southeast of Sparta. It was the home of Castor and Pollux, the "Amyclæan brothers." It was conquered by the Spartans only before the first Messenian war. (2) An ancient town of Latium, which claimed to have been built by a colony from the Greek Amyclæ.

Amygdalin, a-mig'da-lin (from the Latin *amygdala,* "almond"), a crystalline substance occurring in bitter almonds, in the kernels of apples, pears, and peaches, in the leaves of the laurel (*Cerasus lauro-cerasus*), and in the leaves and bark of various species of the genus *Prunus.* It has the formula $C_{20}H_{27}NO_{11}+3H_2O$, and is of special interest to the chemist because it was the first known of the numerous class of substances termed "glucosides" (q.v.). It is obtained by extraction, with boiling alcohol, of the pulp left after the expression of the oil from bitter almonds. The alcoholic solution is concentrated by evaporation, and the amygdalin precipitated by the addition of ether, in which it is insoluble. Like the other glucosides, amygdalin does not form salts with acids, but is decomposed by them with the formation of glucose.

Amyg'daloid, in geology, an igneous rock containing numerous almond-shaped or spherical enclosures of material distinctly different, either chemically or physically, from that which constitutes the rock itself. The enclosures were originally cavities due to the inclusion of steam or gases. Lava frequently exhibits a structure of this kind, its enclosures being commonly calcite or quartz.

Am'yl (from the Latin *amylum,* "starch," its first-known compounds being obtained by the distillation of fermented starchy matter), an important organic radical having the formula C_5H_{11}, and belonging in the fatty series. It is also called "pentyl," because, in the long list of analogous radicals having the general formula C_nH_{2n+1} amyl is the particular radical in which $n=5$. Amyl cannot exist in the free state, but two of its molecules can combine to form the paraffin "decane," $C_{10}H_{22}$, which is a liquid boiling at about 320° F. The radical amyl can have no less than eight different isomeric forms, and the chemistry of its compounds is correspondingly complicated. Of the many compounds that are known, however, only three are especially important in the arts. These are: (1) amyl alcohol, (2) amyl acetate, and (3) amyl nitrite.

(1) Eight isomeric amyl alcohols are theoretically possible, one for each of the theoretically possible isomeric forms of the radical itself; and seven of these are actually known. Five of the seven are of no particular importance in practical chemistry, but the remaining two, known respectively as the "active" and "inactive" amyl alcohols, constitute the greater part of the fusel-oil (q.v.) that is obtained abundantly in the manufacture of potato brandy, and less abundantly in the preparation of many other kinds of distilled liquors. "Active" amyl alcohol has the formula $CH_3.CH.C_2H_5.CH_2.OH$, boils at about 262° F., and takes its name from

the fact that it rotates the plane of polarized light to the left. «Inactive» amyl alcohol has the formula $(CH_3)_2.CH.CH_2.CH_2.OH$, boils at about 269° F., solidifies at —4° F., and has no effect upon polarized light. These two kinds of amyl alcohol may be obtained, mixed, by washing fusel-oil with water, and subsequent rectification. They may then be separated by fractional distillation, or by other more exact methods, for which see special treatises.

(2) Amyl acetate (more exactly, «iso-amyl acetate,» since six acetates are known), is prepared by distilling a mixture of the foregoing amyl alcohols with sodium acetate and sulphuric acid. It is a liquid, boiling at about 282° F., and possessing a strong fruit-like smell. It is used for flavoring cheap confectionery.

(3) Amyl nitrite, $C_5H_{11}.NO_2$, may be formed by distilling a mixture of the foregoing amyl alcohols with potassium nitrite and dilute sulphuric acid. It is a yellow liquid, with an ethereal, fruity odor. When its vapor is inhaled, it paralyzes the vaso-motor nervous system and lowers the blood pressure. Amyl nitrite is often administered in this way for the cure of obstinate hiccoughing. Its effects are powerful and almost instantaneous, and it should never be tried except under the guidance of a physician.

Amylene Hydrate, an alcohol used as a hypnotic. It is technically a tertiary iso-amyl alcohol $[(CH_3)_2C(OH)CH_2CH_3]$, and is a limpid, colorless, neutral fluid with a peculiar odor and a burning taste. It is miscible with eight parts of water and freely miscible with alcohol, chloroform, and fixed oils. It has an action on the human body similar to that of other alcohols, and is a useful hypnotic, occupying a position between chloral, which is twice as strong, and paraldehyde, which has about half the strength of amylene hydrate. In large doses it is a heart depressant.

Amylop'sin, a chemical (or unorganized) ferment, occurring in the pancreatic fluid, together with steapsin and trypsin. The chief function of amylopsin, in intestinal digestion, is to effect the conversion of starches and similar substances (amyloses) into sugars (dextrins, maltoses, isomaltoses, and glucose). The conversion takes place in the small intestine. Amylopsin is often called the «pancreatic diastase.» See PANCREAS.

Am'ylose, any carbohydrate (q.v.) which can be classified as starch, dextrin, cellulose, or natural gum. The remaining members of the carbohydrate group are classed as glucoses or saccharoses. The general formula of an amylose is $(C_6H_{10}O_5)$ n. See CARBOHYDRATE; CELLULOSE; DEXTRIN; STARCH; GUM.

Amyntas, the name of various characters in ancient Greek or Macedonian history, especially kings of Macedonia. (1) A son of Alcetas, reigned about 540 to 500 B.C., and he was succeeded by his son, Alexander I. (2) King of Macedonia, son of Philip, and brother of Perdiccas II.; reigned 393 to 369 B.C., having gained the crown by the murder of Pausanias. He was engaged in war with the Olynthians and assisted by the Spartans. He was father of Alexander, Perdiccas, and the famous Philip. (3) Philip excluded the grandson of Amyntas II. from his succession and he was put to death in the first year of the reign of Alexander the Great because of a plot against the life of Alexander. The 4th was a Macedonian officer in Alexander's army.

Amyntor, Gerhard von, pseudonym of Dagobert von Gerhardt, a German novelist and poet: b. Liegnitz, Silesia, 12 July 1831. He entered the army in 1849, took part in the campaigns of 1864 and 1870–1 as a major, was severely wounded in the former and resigned in 1872; settled in Potsdam in 1874. His principal works are 'Peter Quidam's Rhine-Journey' (1877), an epic; 'Songs of a German Night Watchman' (1878); 'The New Romancero' (1880), poems; 'The Priest' (1881), an epic; novels, 'It Is You' (1882); 'A Problem' (1884); 'Praise of Woman' (1885); and 'Gerke Suteminne' (1887), a historical romance.

Amyot, Jacques, ä-mē-ō', a French author: b. 30 Oct. 1513; d. 6 Feb. 1593. He is famous for his translations from the Greek, which, owing to their elegant style, are considered classical literature. They are the 'Theagenes and Chariclea' of Heliodorus; 'Seven Books of Diodorus Siculus,' the 'Daphnis and Chloe' of Longus; and 'Plutarch's Lives,' which was used by Corneille as a source for his antique tragedies, and by Shakespeare (in its English version by Sir Thomas North) for some of his plays.

Amyraut, Moïse, a French Calvinist theologian: b. in Bourgueil, in the province of Anjou, 1596; d. 1664. He was educated at Saumur, where he was himself afterward a professor of divinity. By his talents and moderation he soon acquired reputation and influence. In 1631 he attended the Synod of Clarendon, and was commissioned to present to the king the remonstrances of his brethren against the infraction of the edicts of pacification. In his mission he acted with such judgment and dignity that he succeeded in relieving the Protestant deputies from the disgraceful obligation of addressing the king on their knees. Although he was a Protestant, his amiable temper and courteous manners commanded the regard of the Catholics, and he was held in particular esteem by Cardinal Richelieu. He endeavored to bring about a complete union between the various Protestant Churches; this object he had in view in nearly all his writings, especially in a Latin tract, '*De secessione ab ecclesia Romana, deque pace inter Evangelicos in negotio religionis instituenda.*' Moreover, acting in concert with Richelieu, he aimed at a reconciliation between the Protestants and the Roman Catholic Church. The favor and respect with which he was treated by the heads of the French government, Richelieu, and Mazarin, are to be ascribed to his opinions concerning the power of the princes. He publicly maintained on several occasions the doctrine of implicit obedience to the sovereign authority, which, indeed, had also been held by the great founders of the Reformation. Amyraut was a finished scholar, and wrote Latin and French with equal ease. His numerous writings, which were received with marked favor in his time, are now nearly forgotten and not easy to be procured. Among the number we may mention 'A Treatise on Religions, Against Those Who Esteem Them to Be Indifferent'; 'Christian Morals'; 'A Treatise on Dreams'; 'Against the Millenarists'; 'Considerations on the Laws of Nature Regulating Marriage.'

Amyridaceæ, a natural order of tropical plants, consisting of trees or shrubs with opposite or alternate compound leaves, frequently stipulate and dotted; the flowers are usually bisexual, but are sometimes unisexual by abortion. They yield resinous and balsamic juices, which are sometimes used medicinally, and receive such names as bdellium, elemi, frankincense, myrrh, olibanum, tacamahac. (See these articles.) Among the chief genera of the order are *Amyris, Balsamodendron, Boswellia, Canarium,* and *Icica.* They are sometimes classed as a suborder of *Anacardiaceæ.*

An, or ON, the Egyptian name of the city of Heliopolis.

Ana, a comparatively modern designation applied to collections of the sayings and observations of eminent persons, as well as to gossip or criticism pertaining to them.

Anabaptists (Greek, ἀνά, again, βαπτίζειν, to baptize), those who baptize again persons admitted to their communion, when such converts have been baptized in their infancy or have been merely sprinkled and not immersed in baptism or have been baptized in any way without being capable of declaring the doctrines which they believe and giving a reason for the hope that is in them. Baptists (q.v.) of the present day are not properly to be styled Anabaptists, as they lay no capital emphasis upon the necessity for rebaptism, although they have very definite canons on the subject of immersion.

Anabaptists of the early Church.— In the 3d century of the Christian era, the century which witnessed such violent and bitter controversies, the question of baptism came also under discussion. In the Eastern Church, including Asia Minor, Egypt, North Eastern Africa and Constantinople, it was definitely maintained that baptism was invalid unless it was administered by one of the clergy with proper matter and form. In the Western Church, including Italy, Gaul, Spain, and North Western Africa, it was held that the virtue of baptism lay in the invocation of the Trinity, and the ceremonial sprinkling with, or immersion in the water. Any baptism thus administered by a person of either sex, by a clergyman or a layman, was equally valid. When two children in their play mimicked the act of a priest whom they had seen baptizing an infant, Saint Augustine of Hippo declared that the boy who had been thus baptized by his companion was a real and actual partaker of the benefits and bound by all the vows pertaining to this sacrament. The controversy between the East and the West continued, however, to rage with such fury that two councils were called to settle the question. The one was held in Iconium, Asia Minor, in 235, the other at Synnada in 256. At these theological synods the decision arrived at was, that rebaptism was unnecessary for those who had been baptized by heretics. The storm of controversy swept westward to Northern Africa as far as Carthage, where Tertullian supported the position of the Eastern Church in contrariety to that of Saint Augustine and other Western doctors. Agrippinus, bishop of Carthage, maintained against the bishop of Rome that baptism under certain circumstances ought to be repeated. His followers were called Agrippinians and his defiance of the bishop of Rome took the form of a concilier decree which was issued by a synod which he convened and which endorsed the sentence of Iconium. In the year 253 Stephen, bishop of Rome, fulminated a bull of excommunication against all the bishops of Asia Minor, including Cappadocia, Galatia and Phrygia, whom he styled Rebaptizers and Anabaptists in an opprobrious sense.

Münster Anabaptists.—In the 16th century there arose in Europe a religious sect known as Anabaptists, whose main tenets carried the principles of the Reformation to the extreme limit of that revolutionary movement. Their principles were those of revolt against mediæval feudalism just as much as against ecclesiastical authority. They were socialists as well as reformers, mystics and fanatics. Their existence was one of the results of the Renaissance as interpreted to the common mind. Their views were democratic and individualistic. They rejected all authority, all tradition, all dogma, everything in short that militated against the absolute independence of the individual mind and spirit. This tendency acquired at length the character not only of liberty but of license, and the term Anabaptist has thus become associated with every extreme, not only of license but of licentiousness, of rebellion and political outlawry. It is quite absurd to associate the term Anabaptist as employed historically with any phase of Christian thought, practice or opinion. It really is a term applied to those who at a turning point in the history of European thought, social, political and religious, became intoxicated with the idea of individual liberty, and the result was violence and excess of the worst character.

The history of the movement is as follows: The doctrine of adult baptism was first put forth by Thomas Münzer, the Lutheran pastor of Zwickau in Saxony, in the year 1520. Münzer soon obtained many followers who joined him in his uprising against all civil and religious authority. Although openly belonging to the Reformation movement they very soon became completely repudiated by the followers of Luther and his adherents. But the spirit of insurrection against feudal tyranny prevailed amongst all the common people on the Rhine, in Westphalia, Holstein, Switzerland, Flanders and throughout the whole Netherlands, and the increase of Münzer's followers became so dangerous that the magistrates and civil authorities found it difficult to restrain them. Münzer was compelled to leave Zwickau; he visited Bohemia, resided for two years at Alstadt and Thuringia and in 1524 was found propagating his doctrines in Switzerland. He was the principal inciter of the Peasants' War, which was entered upon with a view of establishing an ideal Christian commonwealth with communistic institutions. This war reached its culmination in 1525, when Münzer led his forces against the representations of established order and was defeated at the battle of Frankenhausen 15 May 1525, Münzer was taken prisoner and with several of his associate leaders was tried, condemned and executed. But all this was looked upon by the Anabaptists as merely a form of welcome persecution. New associations were formed; new prophets and teachers arose; the propaganda was extended amongst the peasants and serfs of Germany, Austria and Hungary in every direction. It may be necessary to state that the tenets of the Anabaptists are to be

summarized in their own words as follows: "Impiety prevails everywhere. It is therefore necessary that a new family of holy persons should be founded, enjoying, without distinction of sex, the gift of prophecy, and skilled to interpret Divine Revelations. Hence, no need for learning; for the internal word is more than the outward expression. No Christian is to be allowed to go to law, to hold an office in the civil government, to take an oath in a court of justice or to possess any personal property; everything amongst Christians must be in common."

John Bochhold, or Bockel, a tailor, of Leyden, aged 26, and John Matthias, or Matthiesen, a baker of Harlem, came, in 1553, to Münster in Westphalia, a town whose inhabitants followed the doctrines of the Reformation. Here they soon won the adherence of the excited populace, and among the rest, of Rothmann, a Protestant clergyman, and the Councillor Knipperdolling. The magistrates in vain excluded them from the churches. They took violent possession of the council-house, and toward the end of the year a treaty was signed securing the religious liberty of both parties. Being strengthened by the accession of the restless spirits of neighboring cities, they soon made themselves masters of the town by force, and drove out their adversaries. Matthiesen came forward as their prophet, and persuaded the people to devote gold, and silver, and movable property to the common use, and to burn all books but the Bible; but in a sally against the bishop of Münster, who had laid siege to the city, he lost his life. He was succeeded in the prophetic office by Bochhold and Knipperdolling. The churches were destroyed, and twelve judges were set over the tribes, as in Israel; but even this form of government was soon abolished, and Bochhold, under the name of John of Leyden, raised himself to the dignity of king of New Zion, as the Anabaptists of Münster called their kingdom, and as such was ceremoniously crowned. From this period (1534) Münster was the scene of all excesses of fanaticism, lust and cruelty. The introduction of polygamy, and the neglect of civil order, concealed from the infatuated people the avarice and madness of their tyrant and the increase of danger from abroad. Bochhold lived in luxury and magnificence; he sent out seditious proclamations against the pope and Luther, as well as the neighboring authorities; he threatened to destroy with his mob all who differed in opinion from him; made himself an object of terror to his subjects by frequent executions, and while famine and pestilence raged in the city, persuaded the wretched, deluded inhabitants to a stubborn resistance of their besiegers. The city was at last taken, 24 June 1535, by treachery, though not without a brave defence, in which Rothmann and others were killed, and the kingdom of the Anabaptists destroyed by the execution of the chief men. Bochhold, and two of his most active companions, Knipperdolling and Krechting, were tortured to death with red-hot pincers, and then hung up in iron cages on Saint Lambert's steeple, at Münster, as a terror to all rebels. In the meantime, some of the twenty-six apostles, who were sent out by Bochhold to extend the limits of his kingdom, had been successful in various places; and many other teachers, who preached the same doctrines, continued active in the work of founding a new empire of pure Christians, and propagating their visions and revelations in the countries above mentioned. It is true that they rejected the practice of polygamy, community of goods, and intolerance toward those of different opinions, which had prevailed in Münster; but they enjoined upon their adherents the other doctrines of the early Anabaptists and certain heretical opinions in regard to the humanity of Christ, which seemed to result from the controversies of that day about the sacrament. The most celebrated of these Anabaptist prophets were Melchior Hoffmann and David Joris. The former, a furrier from Suabia, first appeared as a teacher in Kiel in 1527; afterward, in 1529, in Emden; and finally in Strasburg, where, in 1540, he died in prison. He formed, chiefly by his bold promises of a future elevation of himself and his disciples, a peculiar sect, whose scattered members retained the name of Hoffmannists in Germany till their remains were lost among the Anabaptists. They have never owned that Hoffmann recanted before his death. David Joris, or George, a glass-painter of Delft, born in 1501, and rebaptized in 1534, showed more depth of mind and warmth of imagination in his various works. In his endeavors to unite the discordant parties of the Anabaptists, he collected a party of quiet adherents in the country, who studied his works (as the Gichtelians did those of Böhme), especially his book of miracles, which appeared at Deventer in 1542, and revered him as a kind of new Messiah. Unsettled in his opinions, he traveled a long time from place to place, till at last, to avoid persecution, in 1554 he became a citizen of Basil, under the name of John of Bruges. In 1556, after an honorable life, he died there among the Calvinists. In 1559 he was accused, though without much reason, of profligate doctrine and conduct, and the Council of Basil ordered his body to be burnt.

Undoubtedly by no means all the Anabaptists of Germany indulged in social and political excesses. The fanaticism which characterized some of the early Anabaptists is sufficiently explained by the tendency of human nature to rush into extremes. The iron hold of the ecclesiastical hierarchy, which had cramped the church for ages, being suddenly relaxed, men had yet to learn what were the genuine conditions whether of civil or religious liberty. But these considerations were overlooked, and the reformed churches, with one consent, regarded the Anabaptists with horror and disdain. The correspondence of the Reformers is full of allusions to the subject. Anabaptists are spoken of with reprobation, and a distinction is not sufficiently made between the sober Christians and the worst fanatics of the party. It is probable, at least, that their faults have been exaggerated even by the best writers.

Anabasis. See XENOPHON.

Anabolism, the building-up process of organic life. The term metabolism (q.v.) is used to express the interchange of the life process constantly going on in living plants and animals.

Anacharsis, the name of a Scythian philosopher who flourished about 600 B.C. and was a friend of Solon, by whose influence he was received into Athenian society. Returning to Scythia, he was put to death because of his performance of certain Greek religious ceremonies.

Modern readers have been familiarized with the name through J. J. Barthélmy's famous 'Voyage du Jeune Anacharsis en Grèce' (1788).

Anachronism, an inversion of chronological relation, unintended or otherwise. In common parlance it is confined to the antedating of customs or events, particularly in imaginative works with a basis of history.

Anaconda, Mont., city, the county-seat of Deer Lodge County: 27 miles northwest of Butte on the Northern Pacific, Great Northern, and Butte, Anaconda & Pacific Railways. It was founded in 1884, following the erection of its great copper-smelting works, which are the largest in the world. They treat daily between 5,000 and 10,000 tons of ore mined in the vicinity. Deposits of graphite and sapphires are found near the city. Anaconda also has large railway shops, brick works, machine shops, and other manufactories, banks, telephone and telegraph service, and daily and weekly newspapers. The Hearst Free Library contains about 6,000 volumes. Anaconda has grown rapidly with the development of its great copper industry. In 1880 it was a small mining camp; ten years later its population was 3,975. Pop. (1900) 9,453.

Anaconda (origin unknown; possibly native name), the largest snake in America (*Eunectes murinus*), sometimes reaching a length of 30 feet. It is found in or near shallow lakes and streams in Brazil, Guiana, and other parts of tropical America, where it spends much of its time in the water. It feeds on small animals, is closely related to the boa constrictor, and is not venomous. Ornamental leather is prepared from its skin, which is bright brown, marked along the back with blotches, and along the sides with rings of darker color. Compare Boa.

Anacreon, a famous Greek lyrist: b. Teos, about 560 B.C.; d. 476 B.C. Long resident at the court of Polycrates of Samos, he went to Athens in 522 and was distinguished by the favor of Hipparchus. His principal themes were love and wine, but he was a satirist as well. He was greatly esteemed throughout Greece, great honors being paid to his memory. Only two complete poems and some fragments of his works are extant, the well-known 'Anacreontea' being poems after his manner, but dating from a very much later period.

Anadir, or **Anadyr Bay**, a large inlet of Bering Sea, much frequented by whaling-vessels. It is about 250 miles wide, a peninsula of half that breadth lying between it and the Arctic Ocean.

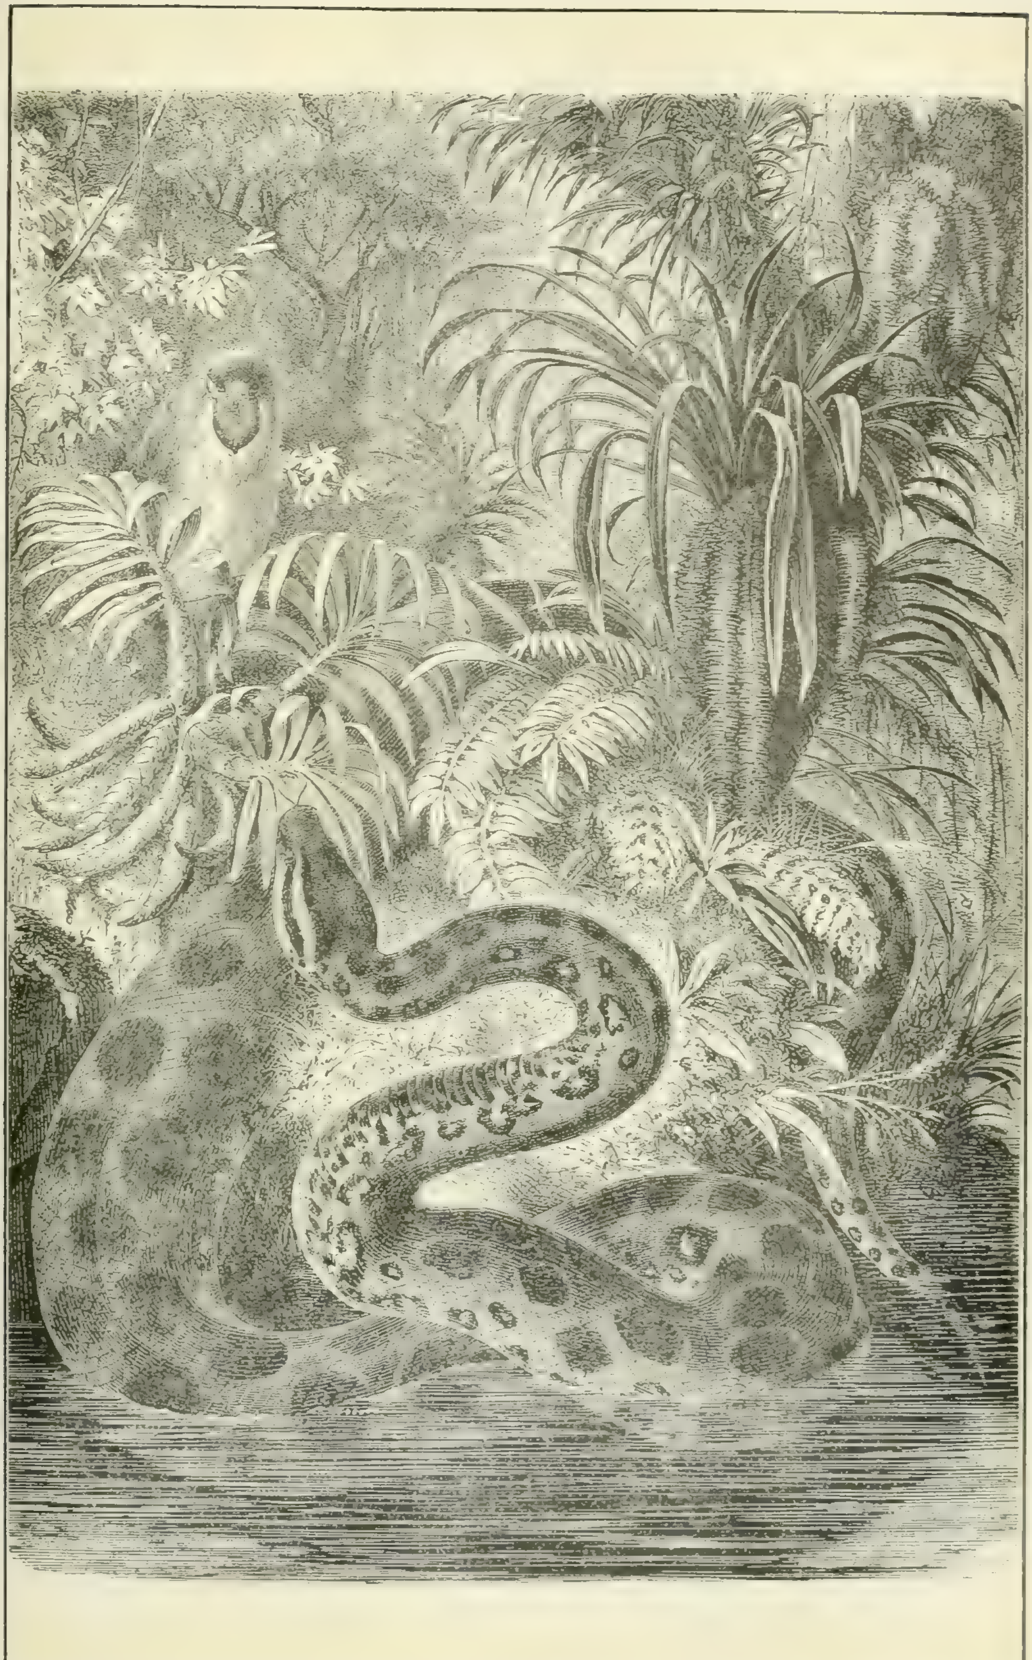
Anadir, or **Anadyr**, the most easterly of the larger rivers of Siberia. It rises in the Stanovoi Mountains, and falls into the Gulf of Anadyr after a course of some 400 miles.

Anadyomene, a surname of Venus, and referring to her as rising from the sea. It was applied by the ancients to a picture by Apelles, which represented the goddess emerging from the waters.

Anæmia, literally without blood, popularly poorness of blood. In medicine, however, it may apply to two very different classes of disease in which there may be a reduction of the amount of the blood, in its entirety, in its corpuscles, red or white, or in one particular, or important ingredient, as the red coloring matter of the blood, the hemoglobin. These two are secondary and primary anæmias. Secondary anæmia may follow a hemorrhage, long-continued wasting disease as Bright's disease, suppuration, tuberculosis, cancer, gastric ulcer; may result from inanition; may be due to the presence of intestinal parasites, notably the hook-worm disease, *Uncinaria* (the poor whites of the South, earth-eaters, etc., seem to have this disease); or may result from acute or chronic poisoning as from animal parasites, malaria; or plant parasites, the bacteria, in the acute infectious diseases; or the poison may be inorganic, such as lead, mercury, copper, or arsenic. Primary anæmia includes two diseases: Chlorosis (q.v.), the green-sickness of young girls; and pernicious anæmia (q.v.), a peculiar disease of the blood-making organs. See Blood Diseases.

Anæsthesia, the loss or impairment of sensibility, a term usually applied to the diminution or loss of the senses of touch or pain (*analgesia*, or temperature sensations), but may apply to the diminution of the sense of smell (*anosmia*), or olfactory anæsthesia; that of sight (retinal anæsthesia) taste (*agustia*), of the muscle sense, of the sense of hearing, or any of the special senses. Anæsthesia of any of these different varieties may result from injury to any part of the sensory nervous chain or neuron (q.v.). If the injury involves the external portions of the sense organs, which are different for all types of sensations, as in a cut of the wrist including a sensory nerve, the anæsthesia is termed peripheral anæsthesia; if the sensory nerve centres are affected, as in some apoplexies, it is termed a central anæsthesia. Anæsthesias may be general or local; complete or incomplete; permanent or transitory; unilateral, on one side of the body (hemianæsthesia), due to injury of the spinal cord or brain on the opposite side; or bilateral, usually due to some symmetrical lesion of the spinal cord, as in myelitis, broken back, tumor pressing on the cord, syringomyelia, locomotor-ataxia, hysteria, etc. The tracing of the nerve fibres to and from an area that is anæsthetic makes one of the most fascinating studies in medicine. Certain drugs, such as cocaine, aconitum, chloroform, ether, etc., also occasion anæsthesia. See Anæsthetics; Sensation. (References: 'Dictionary of Philosophy and Psychology,' Baldwin (1903); Flechsig & Bechterew, 'Die Leitungsbahnen im Gehirn und Rückenmark'; E. Long, 'Les Voies Centrales de la Sensibilite Générale,' 1899.)

Anæsthetics, agents used to produce anæsthesia, a word first employed by Dr. Oliver Wendell Holmes. In early times it was known that pressure on the carotid arteries on each side of the neck could bring about temporary unconsciousness and resultant anæsthesia. The gentle art of garrotting grew out of this generalized knowledge. Ancient peoples used opium, *cannabis indica*, and alcohol to produce anæsthesia, particularly analgesia, or relief from pain, but it was not until the early part of the 19th century that the discovery of the general anæsthetics, nitrous oxid, ether, and chloroform was made, and still later the wonderful develop-



ANACONDA (Eunectes murinus).

ments made in the art of local anæsthesia by the use of cocaine and its congeners.

For remedial measures anæsthesia may be local or general. Cold from ice, or from freezing mixtures, ethyl chloride, etc., is a very efficient local anæsthetic for the performance of small operations, such as opening boils, felons, etc. A large number of drugs have the power of numbing the sensory nerves of the skin and are extensively employed to relieve itching and soreness. These are mostly of the phenol or carbolic acid group, thymol, menthol, etc. Even more efficient in its action on the sensory nerve filaments is the alkaloid cocaine, obtained from the South American coca plant. Applied in appropriate watery solution (2 to 4 per cent) to the mucous membrane of the ear, eye, nose, throat, urethra, vagina, or rectum, it quickly brings about loss of all pain sensations, or, injected into the skin, causes complete anæsthesia over a circumscribed area, permitting of cutting operations. When injected into the spinal canal it brings about complete loss of pain sense in all portions of the body below the site of the injection, sometimes even more extensively. This method of inducing anæsthesia without loss of consciousness has some very advantageous features in surgical procedures and was first practised by a New York physician, Dr. J. Leonard Corning. Other related alkaloids, eucaine, holocain, have similar properties to cocaine. Still other compounds made by the synthetic chemist have been widely employed, principally as analgesics (q.v.).

General anæsthesia is usually brought about by the inhalation of some vapor. Nitrous oxid gas, chloroform, ether, ethyl chloride, etc., are those most frequently employed, especially the three former. Nitrous oxid (q.v.) was the first of this series to be suggested. It was made by Sir Humphry Davy in 1800, but was not used in practice until about 1844, when Dr. H. Wells, an American dentist, employed it in the extraction of teeth.

The anæsthetic properties of ether were known for some years before put to practical use. As to its first use there is much controversy. It seems certain that one Dr. Crawford W. Long of Georgia first used ether as a general anæsthetic, but to W. T. G. Morton, a dentist of Boston, should be given the credit for demonstrating its value and use to the medical profession. Long did his first operation under ether 30 March 1842, for the removal of a cystic tumor of the jaw. He reported his experiments to the Georgia State Medical Society in 1842. Morton's work was begun in 1846, on 30 September, when he extracted a tooth while the patient was under the influence of ether. He subsequently demonstrated his method at the Massachusetts General Hospital, and then patented his product under the name Letheon.

The following year Sir J. W. Simpson of Edinburgh announced the discovery of the anæsthetic properties of chloroform and demonstrated its value in obstetrics. At the present time all three of these anæsthetics are extensively employed. In Europe chloroform is preferred; in this country ether is used more often. The statistics of deaths following these two shows ether to be the less dangerous, although it has more disagreeable after-effects than chloroform. Chronic bronchial and kidney disease contra-indicate the use of ether, while in respect to people with weak hearts chloroform is to be avoided. See CHLOROFORM; ETHER; NITROUS OXIDE.

Anagni, a town of Italy, 40 miles east-southeast of Rome. It was the birthplace of four Popes — Innocent III., Gregory IX., Alexander IV., and Boniface VIII., and as the chief city of the Hernici was a place of importance during the whole period of Roman history. Virgil mentions it as "wealthy Anagnia." Pop. (1901) 10,059.

Anagram, a word or sentence resulting from the transposition of the letters of a given word or form of words. The most exact anagram, sometimes termed palindrome, is that formed by reading the letters backward — evil, for example, thus read, constituting live. The making of anagrams was a favorite mediæval amusement and is still an occasional pastime.

Anaheim, Cal., city in Orange County, situated in a fertile valley, 28 miles south of Los Angeles, on the Southern P. and Santa Fe R.R.'s. It is the centre of the wine trade for southern California, producing over 1,000,000 gallons annually. Anaheim has a public library, high schools, Saint Catherine's Academy, and 11 churches. It was settled in 1859. Pop. (1900) 1,456.

Anahuac, a name applied to the great central plateau of Mexico, elevated from 6,000 to 9,000 feet above the sea and including more than the area of the republic. It contains several lakes, and Popocatepetl is the loftiest of the volcanoes which rise from it.

Anaïtis, the Persian water goddess of antiquity, extensively worshipped in the East.

Anakim ("long-necked ones" = giants), a general term, like Amorites or Rephaim, used by the Hebrews for the pre-Jewish inhabitants of Palestine; but with special reference to the colossal stature accredited to them, as by others to the wild fierce tribes they encountered on first entering their adopted land. Like the Greek giants, they were mountain-dwellers (Josh. xi. 21-2), all through Judah and Israel as later divided, and apparently with palisaded strongholds at Hebron and other places. This passage says Joshua drove them thence, but that remnants survived at Gaza, Gath, and Ashdod, then or later Philistine cities. An older passage, however, says in the Authorized Version that it was Caleb who expelled "the three sons of Anak," whose names are given, from "the city of Arba [Kirjath-Arba] (the father of Anak), which is Hebron." But this is a ludicrous misapprehension of the scribe. "Sons of the Anakim" means in Oriental phraseology clans of that people, here turned into a person with personal sons. The other part is still more grotesque. "Kirjath-Arba" means "city of four" (probably from the incidents of its settlement); but the scribe has taken "Arba" for a person. If the oldest text spoke of the city of the "father of the Anakim" (that is, their ancestral home).

the metaphor is intelligible enough; but as such metaphors in the East are usually feminine, it is most likely the original said "mother of Anakim," and the copyist corrected a supposed error.

Analcite, a-nal'sīt (from the Greek word meaning "weak," in allusion to the feeble electric properties it manifests when heated or rubbed), a mineral usually classed as a zeolite, or hydrated double silicate of sodium and aluminum, with the formula $NaAlSi_2O_6 + H_2O$; although Doelter maintains that the water cannot be water of crystallization, and writes the formula thus: $NaAlSiO_4 + 2H_2SiO_3$. Analcite is commonly colorless or white, with a vitreous lustre. Its hardness is from 5 to 5.5, and its specific gravity about 2.26. It occurs in a variety of forms, but usually in trapezohedrons. There has been much controversy over its crystalline structure, owing to certain optical anomalies that it exhibits; but it is now usually referred to the isometric system, the weak double refraction that it often exhibits being probably due in part to anomalous internal stresses, and in part to a loss of water, and a consequent modification in molecular structure. Beautiful crystals of analcite are found near Mount Ætna and in Nova Scotia. In the United States the mineral occurs in the trap rocks of northern New Jersey, Colorado, California, and the Lake Superior region. See LEUCITE.

Analemma, a geometrical term implying the projection of a sphere upon the plane of a meridian with the point of sight an infinitely distant point of the radius perpendicular to that plane. This projection is sometimes styled orthographic. The sun-dial has been called an analemma, and the term has also been used to indicate a scale showing the declination of the sun and the equation of time of various periods of the year.

Analgesics, remedies used to control pain. These have come largely into use during the past 10 to 15 years. Before that time the profession had to rely chiefly on a few drugs, notably opium, cannabis indica, and their allies, for the relief of pain of nerve and muscle: neuralgia, acute rheumatism, sick headache, and other transitory or persistent affections of the sensory nerves. Synthetic chemistry has introduced a large number of new drugs that have been found very useful in allaying the pain and discomfort of many conditions heretofore borne with heroic stoicism. The commonest of these new remedies are antipyrine, acetanilide or antifebrin, and phenacetin. These are but a few of a large list of similar drugs. The numerous drug-store mixtures sold as headache powders, etc., are usually mixtures of the cheapest of these, acetanilide or antifebrin, with other products. See ANÆSTHETICS; ANTIFEBRIN; ANTIPYRETICS; PHENACETIN.

Analogue, a term in comparative anatomy employed to denote resemblances, as an organ of an animal or plant performing the same function as another part in a second animal or plant differently organized. It is much used by geologists in comparing fossil remains with living specimens.

Analogy, a correspondence of relations between one thing and another.

In logic it implies the resemblance of relations, a meaning given to the word first by the mathematicians. To call a country which has sent out various colonies the mother country implies an analogy between the relation in which it stands to its colonies and that which a mother holds to her children.

As more commonly used it is a resemblance on which an argument falling short of induction may be established. Under this meaning the element of relation is not especially distinguished from others. "Analogical reasoning, in this second sense, may be reduced to the following formula: Two things resemble each other in one or more respects; a certain proposition is true of the one, therefore it is true of the other." If an invariable conjunction is made out between a property in the one case and a property in the other, the argument rises above analogy, becoming an induction on a limited basis; but if no such conjunction has been made out, then the argument is one of analogy merely. According to the number of qualities in one body which agree with those in another, may it be reasoned with confidence that the as yet unexamined qualities of the two bodies will also be found to correspond. Metaphor and allegory address the imagination, while analogy appeals to the reason. The former are founded on similarity of appearances, of effects, or of incidental circumstances; the latter is built up on more essential resemblances which afford a proper basis for reasoning.

In zoology analogy is applied to the resemblance between the entire bodies, or between special structures of organs, in animals of unrelated types. Thus a whale is analogous in form to a fish, its paddles analogous to the fins of a fish. The wings of an insect are analogous to those of a bird. Analogy implies a dissimilarity of structure of two organs, with identity in use or function, as the legs of a bird or quadruped and those of an insect. These analogies are the result of the adaptation of the animal to similar habits, modes of life, or like environment, and result in convergence (q.v.), parallelism, and sometimes mimicry (q.v.). (See also HOMOLOGY.) Osborn defines analogy in evolution as embracing similar changes due to similar adaptation in function both in homologous and in non-homologous organs, both in related and in unrelated animals. The different grades of analogy are shown by Osborn in the following table:

ANALOGY IN EVOLUTION.

Analogous Variation (Darwin): Similar congenital variations in more or less distantly related animals and plants.

Parallelism: Independent similar development of related animals, plants, and organs.

Convergence: Independent similar development of unrelated animals, bringing them apparently closer together.

Homoplasy (Lankester) (? *Homomorphy*, Fürbringer): Independent similar development of homologous organs or regions giving rise to similar new parts.

Analogy of Religion, The, a famous work by Bishop Joseph Butler, published in 1736. The full title is 'The Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature.' The author lays down three premises,— the existence of God; the known course of nature; and the necessary limitations of our knowledge. These enable him to take common ground with those whom he seeks to convince — the exponents of a "loose kind of deism." In no sense a philosophy of

religion, but an attempt to remove common objections thereto, the work is necessarily narrow in scope; but within its self-imposed limitations the discussion is exhaustive, dealing with such problems as a future life; God's moral government; man's probation; the doctrine of necessity; and most largely the question of revelation.

Analysis, in common speech, the act of analyzing; the state of being anlayzed; the result of such investigation. The separation of anything physical, mental, or a mere conception into its constituent elements. It is also applied to a syllabus, conspectus, or exhibition of the heads of a discourse; a synopsis, a brief abstract of a subject to enable a reader more readily to comprehend it when it is treated at length.

In mathematics the term analysis signifies an unloosing, as contradistinguished from synthesis, a putting together. The analytical method of inquiry has been defined as the method of ascertaining the truth of a proposition by first supposing the thing done, and then reasoning back step by step till one arrives at some admitted truth. Analysis in mathematics may be exercised on finite or infinite magnitudes or numbers. The analysis of finite quantities is the same as specious arithmetic or algebra. That of infinites, called also the new analysis, is especially employed in fluxions or the differential calculus. But analysis could be employed also in geometry; it is therefore a departure from correct language to use the word analysis, as many do, as the antithesis of geometry; it is opposed, as already mentioned, to synthesis, and to that only.

As to analysis in chemistry, see CHEMICAL ANALYSIS.

Analytica, The, a treatise by Aristotle, is the third in that philosopher's 'Organon,' or 'Instrument,' and includes in general all that concerns the art of reasoning. Aristotle does not call his system logic, or claim to have invented it; but his theory is so perfect that no philosopher has been able to add to it any element of importance since it was first advanced. The 'Analytica' is divided into two parts: the first dealing with the form of every demonstration; the second, with the demonstration itself. In the first dissertation he treats of the terms composing a proposition, defines a syllogism, and shows how it is constructed. In the second treatise Aristotle discusses the logic of science.

Analysis Situs. Let a geometrical figure—say a closed surface in common space—be subjected to any change of form (bending, stretching, etc.) that does not involve any «tearing» or «joining.» An extensible rubber model will suggest the possibilities of such deformation. Whatever properties of our figure are unalterable by this process form the subject-matter of *analysis situs*, which may therefore be defined as the *theory of invariants of the group* (or groups, see this term) *of continuous deformations*. Its scope, however, is not confined to common space, but embraces, in general, m-dimensional figures in n-dimensional space (more briefly: R_n or n-space, also m-surfaces for m-dimensional surfaces, etc.).

The effect of *tearing* a surface or making an *incision* on it along a line, is to double the latter. As the incision proceeds it substitutes for each point P of the line two points, P_l, P_r, henceforth not to be considered as consecutive, and whose successions separately constitute the left and right edges of the incision. *Joining* is the opposite process, each point of the juncture consisting of twin points merged into one. Corresponding definitions apply to incision and juncture along surfaces of two or more dimensions, or when the elements considered are straights, planes, etc., instead of points.

It will here be noticed that figures which are not continuously deformable into one another, or *equivalent*, in n-space, may become so by virtue of the additional freedom of deformation that $n+1$-space affords. The figure of two concentric circles in a plane is not equivalent to two circles excluding one another, but becomes so in 3-space. Hence a distinction arises between *absolute* analysis situs, which places its figures in space of any suitable number of dimensions, and analysis situs *in a given space or surface* within which all deformation must take place.

C. Jordan has shown that in the case of *2-dimensional surfaces* the following four invariants form a complete system. This means that any two surfaces agreeing in these data are equivalent: (1) the number of detached portions of which they consist, and, with regard to each of these: (2) the number of curves bounding it; (3) its connectivity; (4) its laterality (unilateral or bilateral type). Evidently the first and second of these could be changed by incision or juncture only.

Connectivity.—A surface is *connected* if it permits of continuous passage on it between any two of its points. The standard of connectivity is the area of a plane triangle, circle, or equivalent figure, which is called *simply-connected* or *elementary*. On it any two curves C_1, C_2 (not intersecting themselves or each other) between two points, A, B, are equivalent, for taken together they form a closed curve which divides the plane into two separate portions. This latter property received analytical demonstration from Jordan (hence «Jordan curves») and has lately been based on the theory of assemblages by Veblen. Using Poincaré's notation we write

$$C_1 \equiv C_2 \quad \text{or} \quad C_1 - C_2 \equiv 0,$$

where the negative sign means that the curve is to be taken in the opposite direction (from B to A), and equivalence to zero means unlimited contractibility. A spherical or ellipsoidal surface is also simply connected, with this difference, that closed curves, if one obstacle (a small circle or «puncture» of the surface) be placed in the way of their contraction, may still be reduced to zero by deformation in the opposite direction. Consider, for instance, the intersection of such a surface with a movable plane as the latter moves parallel to itself in either of two directions.

Extending our definition of equivalence to zero, to sums of curves on any surface, it becomes necessary to stipulate (1) that the order of terms of a sum must be preserved (non-commutative addition) and (2) that any portions of curves, if deformed so as to coincide and form negatives of one another, shall cancel. Thus on the surface of the double ring (Fig. 1) we have

$$C_1 + C_2 \equiv C_3 \quad \text{or} \quad C_1 + C_2 - C_3 \equiv 0.$$

Curves form an *independent set* on a surface if none and no sums of them are equivalent to

zero. Curves containing portions equivalent *inter se* (as when coiling several times about a

FIG. 1.

cylinder) shall here be excluded. *Multiply-connected* surfaces are then said to have *connectivity* c if they permit of c independent paths between any two points A, B. The connectivity of a closed surface, *i.e.*, one without boundary and yet having all its points at finite distances, is not changed by puncturing it. For instance, the intersection of the double ring of Fig. 1 with a plane remains equivalent with itself (and to zero) no matter how the plane moves.

Taking B at an infinitesimal distance from A, all paths between them but those equivalent to the shortest one, approach closed curves (Fig. 2). Hence there are $c-1$ independent

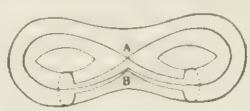

FIG. 2.

closed curves on a surface of connectivity c. Conversely, an independent set of $c-1$ closed curves does not divide the surface (for this would give rise to an equivalence between those bounding any portion of it) and can readily be so connected with two points A, B, as to form (after slight changes) $c-1$ paths from A to B, in addition to which there is the direct line joining these points.

Connectivity is often investigated by the *method of sections*. The latter are incisions of three types: (1) *cross-sections* between two points on the boundary. They may be *bound-severing*, if drawn between points of the same bounding-curve, or *bound-joining*, if between different ones. The former increase, the latter diminish, the number of boundaries by unity. (2) *re-entrant sections*, along closed curves, each furnishing two new rims; (3) σ- (sigma-) sections, starting at a boundary point and ending at a point of their own right or left edge. These contain a re-entrant section and a bound-joining section, and increase the number of bounding-curves by unity.

Limiting our investigations to surfaces any sufficiently small area of which may be considered simply connected, we may divide any one, or system of several, of them by a sufficient number (q) of cross-sections into (say, e) elementary areas. Since cross-sections start at a boundary, we must give a boundary to closed surfaces by puncturing them, *i.e.*, taking out an infinitesimal area somewhere. The difference $e-q$ then proves characteristic of our system of surfaces, and in fact is known as its *characteristic*: $K=e-q$.

To prove this, let a second division, by q' cross-sections, yield e' elementary areas. Superpose the tracings of both divisions and let there be t crossings of the proposed incisions. Then the e areas left whole by the first division will be cut $q'+t$ times by the second, or the e' areas of the second $q+t$ times by the first. Both sets of incisions thus furnish $e+q'+t=e'+q+t$ parts, which proves the proposition. We also see that the characteristic of a system of surfaces is the sum of their individual characteristics.

Any surface can be rendered simply connected by means of $1-K$ cross-sections, for let the q cross-sections which divide it into e elementary areas be traced, and let them meet in v vertices. Consider this division as a map of e districts, the traces, counted from vertex to vertex, being its frontiers. Between any adjacent districts obliterate one frontier (thereby also removing two vertices). Repeat this operation on the new map, etc., until but one district remains. By what we have proven, the totality of remaining frontiers then constitute $1-K$ cross-sections.

On the other hand the $c-1$ nearly closed curves connecting A with B (see above) can readily be turned into cross-sections if we first draw a re-entrant section in a circle of diameter AB, thereby «puncturing» the surface. Hence, on closed surfaces, $c-1=1-K$, or $c=2-K$, and if we retain this formula, the connectivity of a system of m surfaces will prove to be the sum of the individual connectivities, diminished by the number $(m-1)$ of junctures necessary to make one surface of the system:

$$c=\Sigma c_i-(m-1)=1+\Sigma(c_i-1).$$

Kronecker's researches have led to an *analytical expression for the characteristic* of a closed analytical surface $f(x, y, z)=0$. Let $f(x, y, z)$ be negative in the interior of this surface, and consider the family of surfaces $f(x, y, z)=\lambda$. As λ increases from $-\infty$ to 0, the surface has no real part at first, then, through the stage of isolated points or curves, real surfaces will develop. An isolated point develops into an ellipsoidal surface, increasing K by 2, while a closed curve (without multiple points) becomes an anchor-ring, leaving K unchanged. This, or the opposite, may occur several times as the parameter increases. Also, double points of the surface may arise, in the neighborhood of which the surfaces resemble one- or two-sheet hyperboloids, changing from the one shape to the other as the double-point stage is passed. In each of these cases the increase of K is found to be $-2\,\mathrm{sgn}\begin{vmatrix} f_{11} & f_{12} & f_{13} \\ f_{21} & f_{22} & f_{23} \\ f_{31} & f_{32} & f_{33} \end{vmatrix}$, sgn (signum) meaning ± 1 according as the determinant is positive or negative, and

$$f_1=\frac{\partial f}{\partial x},\quad f_2=\frac{\partial f}{\partial y},\quad f_3=\frac{\partial f}{\partial z},\quad f_{11}=\frac{\partial^2 f}{\partial x^2}=\frac{\partial f_1}{\partial x},$$

$$f_{12}=\frac{\partial^2 f}{\partial x\partial y}=\frac{\partial f_1}{\partial y},\ \text{etc.},$$

being partial derivatives.

Examples.—(1) The surfaces formed by rotation of the lemniscates

$$[(x-a)^2+y^2][(x+a)^2+y^2]-a^4=\lambda \quad \text{(Fig. 3)}$$

about the x-axis. For positive λ they present single sheets of ellipsoid connectivity ($K=2$), for negative λ, pairs of sheets of the same kind ($K=4$). Within an infinitesimal sphere about the origin the transition is from the one-sheet to the two-sheet hyperboloid, as λ decreases through zero. At $\lambda=-a^4$ the two sheets be-

come isolated points and vanish ($K=0$). (2) The surfaces formed by rotation of the same

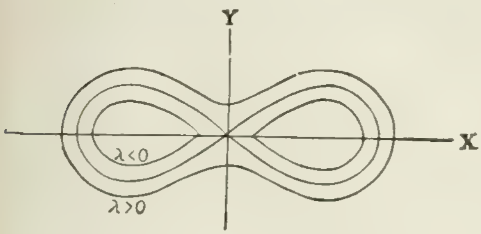

FIG. 3.—Lemniscates.

lemniscates about the y-axis. At $\lambda=-a^4$ they reduce to an isolated curve and vanish without changing the characteristic ($K=0$).

Thus K becomes $-2\Sigma\,\text{sgn}\begin{vmatrix} f_{11} & f_{12} & f_{13} \\ f_{21} & f_{22} & f_{23} \\ f_{31} & f_{32} & f_{33} \end{vmatrix}$, the sum to be taken over all points of intersection of the three surfaces: $f_1=0$, $f_2=0$, $f_3=0$. Moreover, this expression lends itself to transformation into the integral by means of which Gauss represents the «total curvature» of the surface $f(x, y, z)=0$, so that we finally get:

$$K=\frac{1}{2\pi}\text{ total curvature.}$$

Connectivity of Riemann Surfaces.—If w be an n-valued algebraic function of the complex variable z (see COMPLEX VARIABLE), let all values of z be represented on a spherical surface. Superpose radially n copies or sheets of this surface and imagine that for one value z_0 for which the n w-values are distinct, one value of w belongs to each z_0, *i.e.*, to each of the n sheets. The values $w_1 \ldots w_n$ will vary continuously with z, constituting n branches of the function w. For some values of z, however, say for $z=b_1$, $b_2, \ldots, b_m$, some among the quantities $w_1 \ldots w_n$ will turn out equal. In these points we assume connection between the corresponding sheets, and denote them as branch-points. Such connection may not be feasible where other sheets intervene. In 4-space this difficulty would not arise. Limited as we are to 3-space, we may still *suppose* passage possible in these points between the sheets in question. Further, we find that whenever, starting at z_0, we take z in a loop (in all sheets simultaneously) about a branch-point, on returning to z_0 the values $w_1 \ldots w_n$ will have undergone a permutation typical of that branch-point. We prevent such loops, and render the branches single-valued, by means of incisions through all the sheets concerned, from z_0 to each branch-point. We further join every left edge of these incisions with the right one that exhibits the same w-values. This process (which, strictly speaking, again calls for a fourth dimension) completes our Riemann surface.

If we use a circular punch to cut out neighborhoods of the m branch-points (through all the sheets), the portion punched out at b_i, where first β_{i_1} then $\beta_{i_2} \ldots$ sheets are connected, will show $n-(\beta_{i_1}-1)-(\beta_{i_2}-1)- \ldots$ distinct simply connected parts. Thus all branch-points furnish $\Sigma_i[n-\Sigma_j(\beta_{ij}-1)]$ elementary areas. The neighborhood of z_0, similarly punched out, yields n separate circles. The remainder falls into n elementary surfaces by means of m incisions from z_0 to the branch-points, through all the sheets, therefore each counting for n cross-sections. Hence

$$K=2n+\sum_{i=1}^{m}[n-\sum_{j}(\beta_{ij}-1)]-nm=2n-\sum_{ij}(\beta_{ij}-1).$$

One half of the connectivity, viz., $p=\frac{c}{2}=1-\frac{K}{2}$, is known as the *deficiency* of the surface. This is also found to be the difference between the maximal number of double points a curve of the nth order may have, and the actual number of them (d) on the curve $f(x, y, z)=0$: $p=\frac{(n-1)(n-2)}{2}-d$. Besides, p is the number of integrals linearly independent on the surface.

Laterality.—Granting that within a sufficiently small neighborhood of every point P, any of the surfaces we consider has two sides (right and left) distinguished by the two perpendiculars to be drawn from P, it may happen that some continuous path on the surface starting at P on the right side, arrives at P on the left side. The surface is then called *unilateral*; in the absence of such a possibility, *bilateral*. We have hitherto tacitly assumed the bilateral type for our surfaces.

Moebius called attention to the fact that a rectangular strip of paper $aba'b'$, if its sides ba, $a'b'$ be joined after a twist of 180°, as Fig. 4

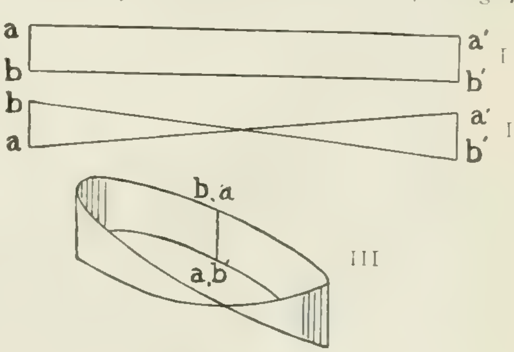

FIG. 4.—Moebius' sheet.

directs, becomes unilateral. *Moebius' sheet* may conveniently be represented by folding the rectangular strip into triangular shape as in Fig. 5. The folds may be distinguished as posi-

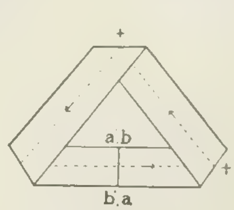

FIG. 5.

tive or negative according as, on our way from ab to $a'b'$, we pass from the lower to the upper sheet or the reverse. Each corresponds to a torsion of $\pm\pi$. Positive folds will cancel against negative ones. Evidently a strip folded into the shape of a polygon of an even number of sides will thus represent a bilateral surface; if the number of sides be odd, a unilateral one. Ruled

surfaces of the third order contain the Moebius sheet (Maschke). Closed surfaces without double points are bilateral.

Indicatrix.—The two normals at a point P, not being in the surface, are more conveniently replaced by a small circle about the point, taken in a definite (say counter-clockwise) rotation about P. On the other side (of this point's neighborhood) the same rotation will be a clockwise one about P. Similarly, within the surface two infinitesimal perpendicular straight lines may be drawn, which if produced would form a right-handed Cartesian coordinate system (see ANALYTIC GEOMETRY) on one side (which we may define as the right one) and a left-handed one on the other. Such alternating contrivances are called *indicatrices* (Klein). They may be distinguished as *right* and *left*, or as *positive* and *negative*. If constructed continuously (*i.e.*, without sudden transition to the opposite one) on continuous paths for all points that can thus be reached, one indicatrix will result for each point on a bilateral surface, while on a unilateral one a point will have both of them. Hence the term *double surfaces* for the latter type.

Unilateral Surfaces.—It will be noticed that Moebius' sheet has one continuous edge. Also,

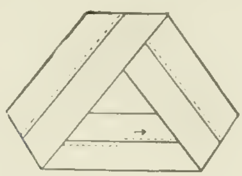

FIG. 6.

if we pursue any closed path, our direction of progress and a direction on the surface perpendicular to the former and pointing to the left may be taken as an indicatrix. Along some

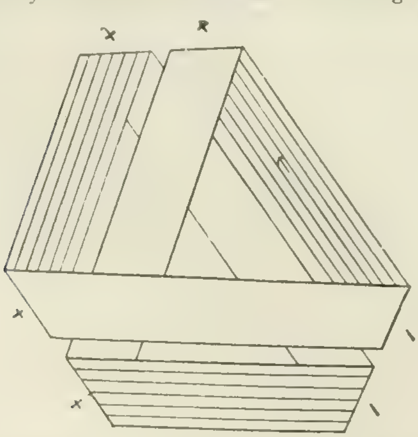

FIG. 7.—Effect of a bilateralizing re-entrant section on Fig. 6. One side is shaded.

closed paths the latter will be reversed. A line closely following such a path on its left will not close, as its beginning and end will be on opposite sides of the path. An incision along the latter evidently leaves our surface connected. Thus, on a unilateral surface, at least one non-dividing re-entrant section can be made. We shall call it a *bilateralizing* one. In fact, the number of bilateralizing re-entrant sections will be that of independent paths along which the indicatrix is reversed. This type of the re-entrant section, however, yields only one new bounding-curve. For only after completing a double circuit about the above closed path will the line following it on the left close in its turn, showing that the two edges of the incision blend into one. There also becomes possible a new kind of cross-section that leaves unchanged the number of boundaries (*bilateralizing* cross-section), as we see by merely tracing a bilateralizing re-entrant section and then making a cross-section that crosses the trace once between two points of one boundary.

Let our surface possess B bounding curves; let it become simply connected by virtue of b bilateralizing, s bound-severing, and j bound-joining cross-sections. Then $j = c - 1 - b - s$, and $B + s - (c - 1 - b - s) = 1$ or $B + 2s + b = c$. Since b is not zero, the number of boundaries of a unilateral surface will always be less than its connectivity: $B < c$.

Two Types of Unilateral Surfaces.—Draw a line connecting two points on different bilateral-

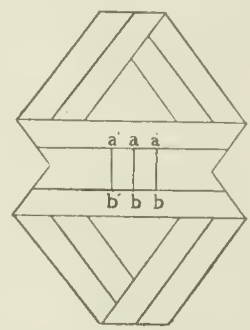

FIG. 8.

izing re-entrant sections. Make the bound-joining cross-sections $\acute{a}\acute{b}$ and $\grave{a}\grave{b}$ immediately to the right and left of it, and rejoin the re-entrant sections along the small portions $\acute{a}\grave{a}$ $\acute{b}\grave{b}$. The

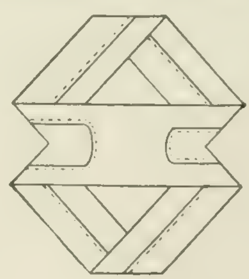

FIG. 9.

result will be a common re-entrant section. For follow by a line immediately to the left the re-entrant section from $\grave{a}$ to $\grave{b}$, the cross-section from $\grave{b}$ to $\grave{a}$, the other re-entrant section to $\acute{a}$ and, finally, the cross-section to $\acute{b}$. It will be seen that this line is closed, and so is the corresponding edge of the whole incision.

After this process of uniting bilateralizing re-entrant sections has been repeated as often as possible, if b is even, no bilateralizing re-entrant sections remain; if b is odd, there will remain

one. Accordingly, there are two types of unilateral surfaces:

(1) $R+2\left(s+\frac{b}{2}\right)=c$, b even: $K=2-c$, when the surface is unbounded ($R=0$), becomes 2, 0, -2, -4 . . .

(2) $R+2\left(s+\frac{b-1}{2}\right)+1=c$, b odd: $K=2-c=1, -1, -3 \ldots$, of $R=0$.

The above surface (Fig. 9) is of the first type, even if extended so as to lose its boundary; $K=0$. Steiner's surface, which is equivalent to the projective plane, is of the second type; $K=1$.

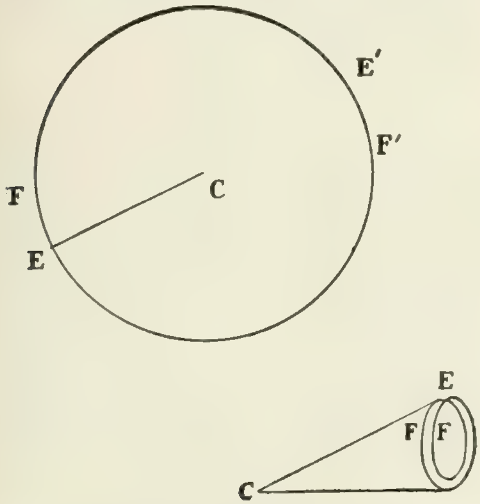

FIG. 10.—Evolution of Steiner's surface.

Steiner's Surface.—Project the points of the projective plane from a center C. On each projecting ray, whose length CP we call r, lay off the segment $\frac{r}{1+r}$ from C. The line at infinity will thus furnish a circle of radius unity, whose diametrically opposite points represent the same point (at ∞) of our plane. Now let the entire new surface, consisting of the ends of the segments laid off from C, be deformed into the plane area of this circle (Fig. 6). Cut the latter from C to E, roll it into a cone, putting CE on CE' (the edges of the incision on different sides). Join the edges of CE (creating a double line) and also, by adjacent points, the two basal circles of the cone. This second juncture, by deformation of the surface, may be made to show continuous curvature, and the apex of the cone may be made to coincide with the center of the circle of juncture. This is Steiner's surface (Fig. 11). By punching out its center and cutting by a plane perpendicular to the double line we get three elementary surfaces. Hence $K=1$, also $c=1$, $b=1$, $B=0$.

Boy has devised similar surfaces and investigated the connection between the characteristic and Gauss' total curvature in such cases.

Two connected surfaces possessing the same number (B) of bounding-curves, the same connectivity and, in case they are unilateral, the same number of bilateralizing re-entrant sections, can now be made simply connected by means of the same number of independent re-entrant sections. After a correspondence has been decided upon between the bounding curves, we draw $c-1$ bound-joining cross-sections between pairs of corresponding ones and further establish a one-to-one correspondence between the points of the original bounding curves, also of these cross-sections. The resulting simply connected surfaces will have their boundaries corresponding point for point. Schoenflies has demonstrated

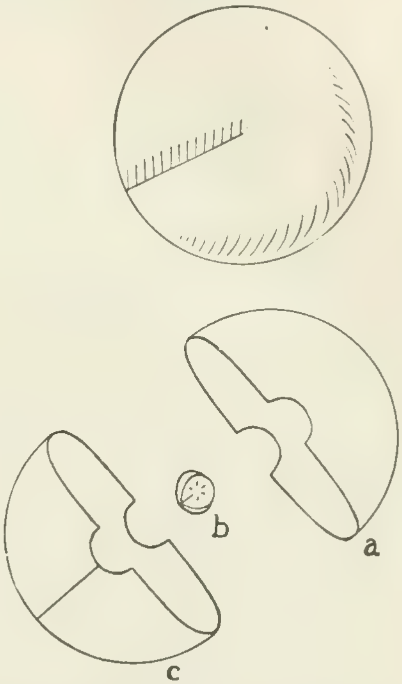

FIG. 11.—Steiner's surface and its connectivity.

that under these conditions between the points in the interior of the simply connected areas, too, a continuous one-to-one correspondence may be established. This proves our surfaces equivalent, verifying the alleged theorem of Jordan.

Space of n Dimensions.—The conceptions introduced in the analysis situs of two-dimensional surfaces in three-dimensional space permit of generalization. The indicatrix of an m-dimensional surface will consist of m directions in (*i.e.*, tangent to) the surface perpendicular to each other. There will be only two indicatrices (right and left), since we may bring about coincidence between a first pair of axes of different indicatrices, then between a second pair, etc. To do this, in the case of the kth pair, we have $m-k$-space at our disposal. This becomes a common plane for the m-first pair. For the last pair there remains a line only, so that coincidence, if not existing, cannot be forced. As a consequence, unilateral and bilateral m-surfaces must be distinguished.

Examples.—The indicatrix of a line is the line-element (or the tangent) taken in one of two possible directions. A closed curve with a cusp might be considered one-sided, as the direction here changes abruptly as we make the circuit. A four-sided prism $abcda'b'c'd'$ in R_4 can be twisted like Moebius' sheet and its face $abcd$ joined to $c'd'a'b'$. The resulting surface is bounded by one bilateral 2-surface (from ab to $cd=a'b'$ and back to $c'd'=ab$) and two

unilateral ones. We may further join these two latter 2-surfaces, their juncture only forming

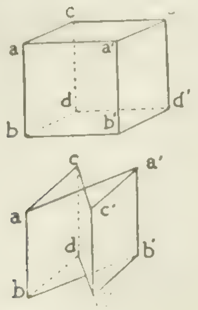

FIG. 12.

a unilateral surface such as we may imagine inside any solid. There will remain only one bounding bilateral 2-surface of spherical connectivity, just as Moebius' sheet has one edge. This further shows that an incision is possible along a surface of spherical connectivity, which does not divide our 3-surface, but renders it bilateral (bilateralizing closed section).

We shall now consider bilateral m-surfaces. They may be given by making the coördinates $x_1 \ldots x_n$ of a point in n-space, functions of m parameters $t_1 \ldots t_m$: $x_i = x_i(t_1 \ldots t_m)$. *$m$-planes* will then be linear functions. Lines, common planes, etc., are m-planes for $m = 1, 2 \ldots$

In n-space, we call surfaces ***complementary*** if their dimensions add up to n, *dual* if they add up to $n-1$. In R_3, lines and 2-surfaces are complementary, while lines are dual to lines (self-dual).

Closed m-surfaces are boundless and contain no points with infinite coördinates. They separate the dual planes of n-space into interior and exterior ones. Taking any complementary plane ($n-m$-plane) that does not intersect the closed m-surface, we can move into it any *exterior* dual plane ($n-1-m$-plane) without allowing it to intersect the surface on the way, can reverse it there by turning it through 180°, and bring it back to its original position along the path on which it was brought. An *interior* $n-1-m$-plane, if we attempted to do the same, would describe an $n-m$-surface which must intersect the given m-surface. Besides distinguishing between the interior and exterior of our closed m-surface this also shows that the interior is bilateral, the exterior unilateral, with regard to the dual planes.

Examples.—(1) The limiting case of a closed figure without dimension is a couple of points. In 1-space (straight line) it bounds a segment. It separates the straights of 2-space (common plane) into those passing between it (interior) and the exterior ones, and does the same for the 2-planes of 3-space. (2) The interior of a circular circumference is an area in 2-space; in 3-space it consists of the straight lines passing through it. Take a plane not intersecting it: an exterior straight line may be moved into the same without coming in contact with the circle, may there be turned through 180° and brought back.—Although points cannot be reversed, it is as natural in an anaylsis situs as in projective geometry to assume unilaterality for the infinite plane. This is merely to extend to a limiting case what is true generally.

Interiors of Different Orders and Degrees.—In a plane a closed curve may have overlapping portions so as to contain a certain area twice or r times. In 3-space it may, without having any double points, coil r times about certain straight lines of its interior, which thereby become an *interior of the rth order*. But if, as we follow the curve in a given direction, it coils p times in an assumed *positive* rotation about this interior of rth order, and $r-p$ times *negatively*, we may then call $p-(r-p) = 2p-r$ the *degree of the interior*. The curve C (Fig. 13) has an interior of

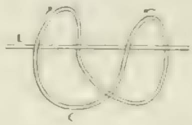

FIG. 13.—Interior of order 2 and degree 0.

order 2 and degree 0, to which line L belongs. These considerations are applicable to n-space, where $n-1$-surfaces, however, cannot possess interiors of higher orders without self-intersection (double points, etc.). Interiors of higher orders than the first can be removed by deformation, unless the curve is knotted (see below).

Locking of Dual Closed Curves.—In n-space a closed m-surface may be locked with a closed $n-1-m$-surface, as are the links of a chain. Through neither of them can a surface one dimension higher than it be laid that does not intersect the other. Examples: A point-couple and a circle enclosing one of its points in a plane. Two linked curves in R_3. For the latter, according to Gauss, the double integral

$$\frac{1}{4\pi}\iint \frac{(x'-x)(dy\,dz'-dz\,dy') + (y'-y)(dz\,dx'-dx\,dz') + (z'-z)(dx\,dy'-dy\,dx')}{[(x'-x)^2+(y'-y)^2+(z'-z)^2]^{\frac{3}{2}}}$$

x, y, z being a point of one curve, x', y', z' one of the other, has the value 1. In the case of one curve coiling repeatedly about the other, the order and degree of their interlocking may again be distinguished in accordance with the reflections of the preceding paragraph. Gauss' integral then gives the *degree*, which may happen to be 0 if the order be even. Two spherical surfaces transplanted into R_5 may interlock.

Knots.—Closed m-surfaces, in $2m+1$-space may lock with themselves. They are then said to form *knots*. The various shapes of knotted curves in common space have been extensively

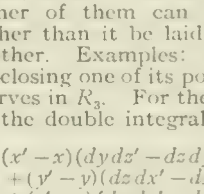

FIG. 14.—Trefoil-knot.

investigated (Listing, Tait, Simony). These researches have been referred to as *topology*, a word also used synonymously with analysis situs. The simplest knot is the so-called trefoil-knot. It is formed by a curve of the sixth order whose equation in tetrahedral coördinates

is given by Brill. It was thought that these knots might be forms of vortex-rings accounting for the differences of chemical elements. There are no knots in 4-space, surface-knots first becoming possible in 5-space, and, in their turn, dissolving in 6-space.

Generalized Connectivity.—m-surfaces will be called connected with regard to tangent lines, 2-planes, etc., if any two of these can be moved into one another without ceasing to be tangent to the surface. Two spheres in R_3, *e.g.*, are disconnected as to points, connected as to tangents and tangent planes. The opposite is true for the faces of a polyhedron. But we shall assume that the surfaces considered possess all these connectivities. With regard to any of them they may be multiply-connected. Connectivity as to points (c_1) is the special case treated above. It has been referred to as cyclosis or periphraxy (Maxwell) in the case of portions of 3-space. The interior of an anchor-ring, *e.g.*, has $c_1 = 2$.

The $c-1$ closed curves by means of which we determined the connectivity of a closed surface in 3-space will lock with other closed curves either in the space enclosed by the surface or in the exterior. We are thus led to consider the connectivity of the portion $(R_3 - S_2)$ left after subtracting from R_3 the points of our surface S_2.

Betti's Numbers of a Closed m-surface S_m.—Imagine S_m, if necessary after continuous deformation, placed in $m+1$-space. Find the connectivities $\bar{c}_1, \bar{c}_2 \ldots c_{m-1}$ of the remainder $(R_{m+1} - S_m)$ with regard to points, lines, 2-planes, . . . $m-1$-planes. These are *Betti's numbers* $P_1, P_2 \ldots P_{m-1}$ of the surface S_m, $(\bar{c}_k = P_k)$. This means that in $(R_{m+1} - S_m)$ there are $P_k - 1$ independent closed k-surfaces with which certain $m-k$-surfaces within S_m may lock. Obviously, the $m-k$-surfaces may be deformed out of S_m into the remainder $(R_{m+1} - S_m)$, while at the same time, and never ceasing to lock with them, the k-surfaces are deformed so as to be on S_m. This shows that P_{m-k} is at least equal to P_k, and vice versa, so that finally $P_{m-k} = P_k$ on any closed bilateral m-surface without double points. Betti's number P_1 for a 2-surface is at the same time its connectivity c.

Euler's Polyhedron Formula.—The theorem holds for any division of a spherical surface into simply connected districts by frontiers bounded by the vertices in which they concur, that $v - f + d = 2$, v being the number of vertices, f of frontiers, and d of districts. Such a map is *regular* if each district has the same number f_d of frontiers, and if an equal number f_v of these concur in each vertex. We have $v = \frac{2f}{f_v}$, $d = \frac{2f}{f_d}$, and $f(2f_d - f_d f_v + 2f_v) = 2f_v f_d$, where $2f_d - f_d f_v + 2f_v$ must evidently be positive. This gives rise to only five regular maps corresponding to the regular polyhedral surfaces of the tetrahedron (self-reciprocal), cube and octahedron (reciprocal to each other), dodecahedron and icosahedron (reciprocal). The regular 4-dimensional polyhedra are found to be six, viz., two self-reciprocal ones bounded by 5 tetrahedra and 24 octahedra respectively, one bounded by 8 cubes reciprocal to one bounded by 16 tetrahedra, and one bounded by 120 dodecahedra reciprocal to one bounded by 600 tetrahedra.

Euler's formula, extended to maps on closed 2-surfaces of connectivity c: $v - f + d = 3 - c$ leads to a superior limit for the number of districts that may be adjacent each to each on such a surface. Heffter has investigated under what conditions this limit is actually attained, while H. S. White shows what regular maps (called by him *reticulations*) are possible for any given c. Generalizing still further, Euler's formula for a *map* on any m-surface, *i.e.*, a division of it into simply connected parts, the dividing $m-1$-surfaces again being divided into simply connected partitions, etc., becomes:

$$\sum_{q=0}^{m-1} (-1)^q n_q = 1 + \Sigma(-1)^q (P_{m-q} - 1),$$

n_q being the number of q-dimensional parts or partitions on the map. Since for closed m-surfaces we have $P_k = P_{m-k}$, if m is even this becomes $\Sigma(-1)^q n_q = 3 - P_1 + P_2 \ldots - P_{m-1}$; if m is odd, $\Sigma(-1)^q n_q = 0$ (Poincaré).

Literature.—Since no treatise on analysis situs has been published, a few of the main papers on the subject will here be mentioned. W. Dyck (Math. Annalen, vol. 32, p. 457) gives the literature preceding his article (to 1888). The pertinent publications of the savants named above are as follows: Listing, 'Der Census raumlicher Complexe' (Göttinger Abhandlungen, 1861), and 'Vorstudien zur Topologie' (Göttinger Studien, 1847); C. Jordan, 'Sur la déformation des Surfaces' (Liouville Journal, sér. 2, 11, 1866); Klein, 'Über den Zusammenhang der Flächen' (Math Annalen 7, 1874); Moebius, 'Werke,' Band 2: 'Über die Bestimmung des Inhalts eines Polyeders' and 'Zur Theorie der Polyeder und der Elementarverwandtschaft'; Gauss, 'Werke,' V, p. 134; Kronecker, 'Berliner Monatsberichte' (1869, p. 159, p. 688, 1873, p. 117, 1878, p. 95); Betti, 'Sopra gli spazi di un numero qua lunque di dimensioni' (Annali di matematica, 1870); Tait, 'On Knots' (Trans. Roy. Soc. Edinburgh, 1879, 1884, 1886; also Proceedings of the same Society, 1876 to 1879); Simony (Math. Annalen 19 and 24); Brill (Math. Ann. 18); Heffter (Math. Ann. 38); Boy (Math. Ann. 57); Maxwell, 'Theory of Electricity and Magnetism' (vol. 1, p. 18); Veblen (Trans. Am. Math. Soc., 1905, p. 83). The subject of analysis situs of higher dimensions, especially of 4-space, has been greatly advanced by the following six recent papers by H. Poincaré: 'Analysis Situs' (Journal de l'Ecole Polytechnique, 1895); 'Complément à l'A. S.' (Proc. London Math. Soc., 1900); 'Second complément à l'A. S.' (Rendiconti del Circolo matematico di Palermo, 1899); 'Sur certaines surfaces algébriques' (Bull. Soc. math. de France, 1902); 'Sur les cycles des surfaces algébriques' (Journal de Math., 1902); 'Cinquième complément à l'A. S.' (Rendic. Circ. mat. di Palermo, 1904).

PAUL WERNICKE,
Professor State College of Kentucky.

Analyzer, the portion of a polariscope (q.v.) employed in the examination of polarized light. Nicol prisms, tourmaline plates, double-refracting crystals, and movable mirrors are each used for this purpose.

Anam, or **Annam**, an Asiatic country on the east side of the Indo-Chinese Peninsula, along the China Sea, about 850 miles long, with a breadth varying from over 400 miles in the north to 100 in the middle. It is composed of Tonquin or Tongking in the north and Cochin-China and Chiampa in the south. The total area

is 170,000 square miles, and the population 15,000,000.

Its coast is much indented, affording many fine harbors, and a mountain range extends its entire length. The Mehong, the principal river, is the boundary between Anam and Siam and is navigated by steamboats. The capital and largest city is Hué. Rice, cinnamon, sugar-cane, coffee, tea, tobacco, and cotton are the chief productions, though silk is manufactured to some extent and fine woods are exported. The government is a monarchy, the king being nominally assisted by a council of six, but French influence predominates.

The inhabitants are from two races, the Mountain Mois, and the Anamese proper, and generally under the middle size and less robust than the surrounding peoples. Their language is monosyllabic and is connected with the Chinese. The religion of the majority is Buddhism, but the educated classes hold the doctrines of Confucius; besides which there are 420,000 Roman Catholics.

Anam was conquered by the Chinese in 214 B.C., but in 1428 A.D. completely won its independence. The French began to interfere actively in its affairs in 1847 on the plea of protecting the native Christians. By the treaties of 1862 and 1867 they obtained the southern and most productive part of Cochin-China, subsequently known as French Cochin-China; and in 1874 they obtained large powers over Tonquin. By the treaty of 1884, ratified at Hué, 1886, Anam was declared a French protectorate.

Anamalai Hills, a range of mountains in the Coimbatore district of Madras, southern India. They lie between 10° 13′ and 10° 31′ North latitude and 76° 52′ and 77° 23′ East longitude. The range is rather a vast table-land with several high summits than mountains. They are covered with dense forests and the brush and jungle growths render habitation impracticable, the only inhabitants being a few wild tribes who live upon the animals which infest the woods and jungle produce. Geologically the mountains are formed of metamorphic gneiss, interspersed with veins of feldspar, quartz, and reddish porphyrite. Teak and other valuable timber may be found on the lower slopes, while a portion of the land has been planted with coffee.

Anamarita. See COCCULUS INDICUS.

Anamorphosis, a term applied to a drawing so executed as to present a distorted image of the object represented, but which, if viewed from a certain point, or reflected by a curved mirror or through a polyhedron, shows the object in true proportion.

Anamosa, Ia., a city and county-seat of Jones County, situated on the Wapsipinicon and Buffalo rivers and on the Chicago & N. W. and Chicago, M. & St. P. R.R.'s. It has a State penitentiary and many excellent quarries of building-stone, and manufactories of flour, carriages, and wagons. Pop. (1900) 2,891.

Ananchytes, a genus of fossil petalostichous sea-urchins of the family *Spatangidæ*, and subfamily *Ananchytinæ*, found in the Cretaceous formation. The name «shepherd's crown» is given to it in the southern part of England and also the name «fairy loaves.» They have a transversed mouth, an oblong outlet, a helmet-like form, and simple ambulacra.

Ananias, a member of the Church at Jerusalem, struck dead with his wife Sapphira because of an attempt to misrepresent the amount of their gifts to the Apostle Peter. The name was also borne by a Damascus disciple named in connection with Saul's adventure there, and by a high-priest in Jerusalem belonging to the Sanhedrim.

Ananier, or **Ananyer,** a Russian town about 220 miles northwest of Kherson, with some little agricultural trade and a mixed population of Russian Jews and Rumanians. It was annexed to Russia in 1792. Pop. (1897) about 17,000.

Anapa, a seaport town of Russia, situated on the Black Sea. It has been variously the possession of Turks and Russians, but has belonged to Russia from 1829. Pop. about 7,000.

Anapæst, in prosody, a foot consisting of two short syllables and one long one. In the comedies of Aristophanes it was the dominant measure, and Greek choruses employed it in their exits and entrances. From this latter circumstance it was frequently styled the marching rhythm.

Ana'phalis, a genus of plant of the tribe *Inuloideæ* of the family *Compositæ*. The characteristics are nearly the same as *Antennaria*, viz.: heads many flowered, diœcious; flowers all tubular; and the pistillate corollas are very slender. Involucre dry and scarious, white or colored, and imbricated. The receptacle is convex or flat, not chaffy; anthers caudate; achenes terete or flattish. The main difference between the two lies in the pappus, as in the *Anaphalis* the pappus in the sterile flowers is not thickened at the summit or scarcely so and that of the fertile flowers not at all united at the base; fertile heads usually with a few perfect but sterile flowers in the center. *A. margaritacea* (pearly everlasting) is found on dry hills and in the woods, is common to the northward and flowers in August. The stem is erect, corymbose at the summit, has many heads and is leafy; leaves broadly to linear-lanceolate, taper-pointed, sessile, and soon green above; the involucral scales are pearly white, very numerous, and obtuse or rounded. Consult: Gray, ‹Manual of Botany› (New York, 1889).

Anaphrodisiacs, ăn-ăf′rọ-dĭz′ĭ-ăks, are remedies that diminish sexual power or desire. They may act directly on the genital centres in the spinal cord, indirectly through the circulation on the brain, or locally on the sense organs. Inasmuch as local irritation is a frequent cause of stimulation of the sexual sense, attention to cleanliness is imperative and the removal of all sources of irritation indicated. There are many simple ways of allaying the excitement for the time, such as the application of ice, and cold baths, local or general, are of great benefit. The diet should also be regulated, spicy, stimulating, and heating foods should be carefully avoided, and the main foods should be vegetables. The clothing should be as light as possible, and if necessary drugs may be administered. Local analgesic applications, such as weak solutions of carbolic acid—1 to 2 per cent—or oxid of zinc ointment with carbolic acid, are useful. Of the general anaphrodisiacs the bromides are the best. Bromide of sodium or potassium is most frequently employed. Special medical advice is needed in the treatment of persistent sexual excitement. See also APHRODISIAC.

Anaptomorphus, a fossil lemur from the Eocene of Wyoming, allied to the modern tar-

sier. Some authorities have considered this animal as related to the ancestral line of man.

Anarchism, a theory of social organization, numbering, it is said, about one million adherents. Its doctrines represent the extreme of individualism. It looks upon all law and government as invasive, the twin sources whence flow nearly all the evils existent in society. It therefore advocates the abolition of all government as we to-day understand the term, save that originating in voluntary co-operation. Anarchists do not conceive of a society without order, but of an order arising out of the law of association, preferably through self-governing groups, for it may be said that, with here and there an exception, anarchists regard mankind as gregarious. «Our object is to live without government and without law,» says Elisée Reclus, the eminent geographer, and to-day the leading anarchist of France. Anarchists do not ignore the enormous economies resulting from the law of association, but insist that the law will be better served in a state of freedom and in the absence of all compulsion. They believe that everything now done by the state can be better done by voluntary or associative effort, and that no restraint upon conduct is necessary, because of the natural tendency of mankind in a state of freedom to respect the rights of the individual. The repression of crime, where crime might arise, could safely be left to spontaneously created organizations, such as the Vigilance Committees in early California, where no State government existed. In the view of Prince Kropotkin, the leading Russian anarchist, no cause for litigation would arise after we had abolished «the present system of class privilege and unjust distribution of the wealth produced by labor, that creates and fosters crime.»

To quote further from Kropotkin: «We are nurtured from our birth to believe that we *must* have government. Yet the history of man proves the contrary. When small bodies or parts of humanity broke down the powers of their rulers and resumed some part of their foreordained freedom, these were always epochs of the greatest progress, economically and intellectually. In the direct ratio to the freedom of the individual he advances.»

It is not easy to sum up in a few paragraphs the leading doctrines of any economic sect and at the same time retain absolute accuracy of statement. It should therefore be said that anarchists, while agreeing that the doctrine of *laissez faire* should be extended to all departments of human activity, are by no means in agreement on all points. There are evolutionary and revolutionary anarchists, and communist- and individualist-anarchists. The point on which all are agreed is in their opposition to compulsory forms of government, and in regarding the necessary despotism of majorities in a democracy as only a little less hateful than the despotism of a monarchy. «Governments are the scourge of God,» says Proudhon, with whom the philosophy of modern anarchism may be said to have begun.

Pierre Joseph Proudhon was born in Besançon, France, in 1809, and died in 1865. Germs of the doctrine of which he is the founder may be traced to much earlier, even ancient periods. Among his modern precursors is William Godwin (b. in Wisbech, England, 1756; d. in London, 1834), who is better known as the author of the novel, 'Caleb Williams,' but who in his 'Inquiry Concerning Political Justice,' which appeared in 1793, advocated the abolition of every form of government, and formulated the theory of anarchistic communism. But modern anarchism as a force in sociologic thought began with the publication of Proudhon's famous essay, 'What is Property' (1840). In it he rejects all law and authority, but in a work which appeared in 1852 entitled, 'The Federative Principle,' he seems to have modified in a measure his former theory of government and favors the formation of self-governing communities. In the former work occurs the phrase which is destined to be forever associated with the name of Proudhon, but which was uttered by the Girondist Brissot a half century earlier, «Property is robbery.»

It was upon the notion that he had furnished a demonstration of this thesis that Proudhon especially prided himself. But this phrase as used by the father of anarchism must be held to apply rather to modern methods of acquisition than to property itself, for Proudhon was an individualist, not a communist-anarchist, and strove, however unsuccessful he was in making himself understood, rather to refine than to destroy the idea of property. In all his reasoning on this point there is much dialectic subtlety, of which, with perverted ingenuity, Proudhon was overfond; but it may be said that what he really sought was the overthrow of all prevailing theories of property with a view to rendering it unassailable from the standpoint of exact equality and social justice. A few years later the doctrines of anarchism in the hands of Michael Bakunin underwent a change from the advocacy of a purely peaceful revolution to one of force. Bakunin was born 1814, died 1876. He was prominent in the Paris Revolution of 1848, was surrendered to Russia and sent to Siberia, but succeeded in making his escape. His principal work, in addition to innumerable pamphlets and addresses, is 'Dieu et l'État.'

«The propaganda by action,» as it is termed, by which it was hoped to inspire such dread and horror as to compel the adoption of measures of social amelioration, or perhaps the overthrow of the state itself, has borne abundant fruit in the attempted assassination of Emperor William in 1878, in the attempt upon the life of the German princes in 1883, in the assassination of President Carnot, of France, in 1894, of the Empress Elizabeth, of Austria, in 1898, of King Humbert, of Italy, in 1900, and of President McKinley, by Czolgosz, in the autumn of 1901. Other anarchist crimes were the throwing of a bomb in the French Chamber of Deputies, in 1893, by Vaillant, and the bomb explosion in Paris, caused by Emile Henry, in 1894.

The Haymarket tragedy of 1886, in Chicago, by which a number lost their lives in an explosion from a bomb thrown by some unknown hand, and which resulted in the trial and conviction of seven professed teachers of anarchism in that city, four to the gallows, two to life imprisonment, and one to a term of 15 years, aroused the attention of the whole civilized world. It is now seen, after the lapse of 17 years, that these men, even if dangerous to the community, were convicted more largely by the existing state of public terror than by any actual evidence connecting them with the throwing of

the bomb. The fact that the pardon of the three who escaped the gallows was petitioned for, after the terror of the time had died away, by some of the most prominent citizens of Chicago, is proof of the change the public mind underwent regarding the accused. The controversy over the justice of their conviction is still unsettled. With these acts of murder and vengeance the purely economic doctrines of anarchism have of course no relation. "The propaganda of action" is repudiated by those who are sometimes termed "philosophical anarchists," to distinguish them from the revolutionary wing. These are represented in this country by Benjamin R. Tucker, in France by Elisée Reclus, and in England by Auberon Herbert. ("It is a mistake to believe that the anarchist idea can be advanced by acts of barbarity."— Elisée Reclus.) This school regards force as fundamentally at war with their ideals. It does not believe that the social revolution can be accomplished by the methods of Bakunin and his school. Proudhon never preached force.

With the policy of "propaganda by action" in this country is linked the name of Johann Most, a former member of the German Reichstag; in France, that of Charles Malato ("I love and admire Vaillant just as some English Republicans love and admire Cromwell, who was also a regicide" — Charles Malato); and in Italy, that of Enrico Malatesta, an anarchist, like Kropotkin, of noble family. ("It seems to me that in the natural order of evolution violence has as much a place as the eruption of a volcano. All great progress has been paid for by streams of blood. I cannot see how the present conditions based upon force can be changed in any other way than by force, and so long as they use force against us we must in self-defense employ violent methods."— Enrico Malatesta.)

As Proudhon was the father of anarchistic individualism, Kropotkin is as indisputably the father of anarchistic communism. Theoretic anarchism for some time subsequent to the advent of its French founder was rigidly individualistic. Max Stirner, a follower of Proudhon in Germany, whose philosophy was more of a blank negation than that of his master, pushed the ego to a point where it more resembles a caricature than a dogma, and Bakunin hated the idea of communism. But in Kropotkin it must be said that the idea of property has reached its disappearing point, and the ideal of anarchism is at the last purely communistic. Kropotkine's life and his romantic career, united with the vast store of knowledge he possesses, give to his professions of anarchism a fascination and a weight. And amiable as is his personality, he is not unsuspected of a sympathy with the Bakunin school of action.

Among the works on anarchism not previously mentioned are Kropotkin's 'Paroles d' un Révolté' and 'La Conquête du Pain,' with a preface by Elisée Reclus, and the latter's 'Evolution et Revolution'; 'The Individual and His Property' by Max Stirner; 'Société Mourante' and 'Société au Lendemain de la Revolution'; 'Declarations' (Paris), by G. Eliévant, a work highly regarded by anarchists; 'Après la Tempête,' by Herzen; magazine articles by Auberon Herbert; and 'Instead of a Book,' by Benjamin R. Tucker. 'Anarchism, Its History and Theory,' by E. V. Zenker, is a work valuable for its thoroughness and its judicial impartiality; 'Die Theorie des Anarchisimus,' by Rudolph Stamler, may be consulted with profit for an examination and refutation of the theories and arguments of anarchism. Among the works closely allied to anarchistic thought should be included the sociologic romance, 'Freeland,' by Theodor Hertzka, of Austria.

JOSEPH DANA MILLER.

Anastasia, Saint, the name of three Christian martyrs. (1) A virgin said to have been a pupil of SS. Peter and Paul, and slain under Nero (54–68 A.D.). She is commemorated 15 April. (2) "The Younger," martyred under Diocletian, 303; wife of one Publius, a pagan, who himself laid an information against her. Two alleged letters of hers in prison have been preserved. The Greeks commemorate her the 22d of December, the Latins the 25th. (3) A Greek maiden of Constantinople, whom Justinian (about 597) sought as a mistress. To escape him she fled to Alexandria and lived there disguised as a monk for 28 years. She is commemorated 10 March.

Anastasius, the name of four Popes, the first and most eminent of whom held that office 398–401. He enforced celibacy on the higher clergy and was a strong opponent of the Manichæans and Origen. Anastasius II. succeeded Gelagius I. in 496; d. 498. Anastasius III. filled the papal chair 911–913. Anastasius IV. was Pope 1153–1154.

Anastasius I., an emperor of the East who succeeded Zeno, A.D. 491, at the age of about 55: b. about 438; d. 518. He distinguished himself by suppressing the combats between men and wild beasts in the arena, abolishing the sale of offices and building the fortifications of Constantinople. His support of the heretical Eutychians led to a dangerous rebellion and his anathematization by the Pope.

Anastasius II., an emperor of the East who was raised to the throne in 713. Attempting various reforms, he was deposed in 716 and became a monk at Thessalonica.

Anastasius, a romance by Thomas Hope, (1819). The author was known to have written some learned books on furnishing and costume; but 'Anastasius' gave him rank as an accomplished painter of scenery and delineator of manners. Anastasius, the hero, a young Greek ruined by injudicious indulgence, is haled before a Turkish magistrate. Discharged, he fights on the side of the Crescent and goes to Constantinople, where he resorts to all sorts of shifts for a livelihood,— jugglery, peddling, nostrum-making; becomes a Mussulman, visits Egypt, Arabia, Sicily, and Italy, and finally dies young, a worn-out and worthless adventurer. The book has passages of great power, often of brilliancy and wit; but belongs to the fashion of a more leisurely day and is now seldom read.

Anastatic Printing, a process by which a facsimile of a page of type or an engraving, old or new, is reproduced in the manner of a lithograph or page of letterpress. The print or page to be transferred is dipped in diluted nitric acid, and, while retaining a portion of the moisture, laid face downward on a polished zinc plate and passed through a roller-press. The zinc is immediately corroded by the acid contained in the paper, excepting on those parts occupied by the ink of the type or engraving.

The ink, while rejecting the acid, is loosened by it and deposits a thin film on the zinc, thus protecting it from the action of the acid. The result is that those parts are left slightly raised in relief, and the plate being then washed with a weak solution of gum, and otherwise treated like a lithograph, the raised parts, being greasy, readily receive ink from the roller and give off a facsimile impression of the original.

Anastomosis, in anatomy the joining of the branches of a vessel with other vessels of the same or a different branch. Anastomoses are found in the arteries, veins, and lymphatics. Anastomoses of nerve and muscle fibres are also spoken of.

An'atase, a mineral more correctly known as OCTAHEDRITE (q.v.).

Anath'ema, a word used in a form of excommunication from the Church. It is properly a Greek word, and was originally applied to an object set apart and devoted to a deity, such as a gift hung up in a temple (being derived from the Greek *anatithēmi*, I lay up); but it gradually came to mean separation from God and men, something accursed; and latterly to pronounce an anathema, to anathematize, became much the same as to curse. *Anathema* occurs repeatedly in New Testament Greek, in the English version being generally rendered "accursed," but once the original word is retained (1 Cor. xvi. 22) along with *maranatha,* the latter serving apparently to intensify the curse, though it is properly a Syriac expression signifying "the Lord will come." The Greek and Roman Catholic Churches both make use of the anathema. In the latter it can be pronounced only by a Pope, council, or some of the superior clergy. The subject of the anathema is thus declared an outcast from the Church. When councils declare any belief heretical the declaration is couched in the following form: *Si quis dixerit,* etc., *anathema sit,* "If anyone says (so and so) let him be anathema." The anathema was thus pronounced by the Vatican Council against opponents of the doctrine of papal infallibility. In the Middle Ages the anathema was freely used. See EXCOMMUNICATION.

Anathoth, a town in Palestine, assigned to the Levites, the birthplace of the prophet Jeremiah and the home of Abiathar the high priest. It was about three miles northeast of Jerusalem, and the small village of Anata occupies its site.

Anat'idæ, a family of swimming-birds, including ducks, swans, geese, etc. See ANSERES.

Anato'lia, the modern name of Asia Minor. See ASIA MINOR.

Anatomy, literally a cutting up; but anatomy usually signifies the special study of the structure of organic bodies, morphology (q.v.) and applies to both animals and plants. Animal morphology is the study of human or other animal forms, the study of the relationship between the forms constituting Comparative Anatomy (q.v.). The study of the minute or microscopical anatomy is termed Histology (q.v.). Developmental Anatomy is the study of the gradual growth of the animal, Embryology (q.v.). In the plant world there are also the correlated branches of Plant Morphology, Comparative Anatomy, Histology, and Embryology. The study of the microscopical structure of the single cell is termed Cytology; of collections of related cells and tissues constituting organs, Organology; thus the study of the bony system is termed Osteology, of the structures of circulation Angiology, of nerve structures Neurology, of the muscles Myology, of the viscera Splanchnology, etc. Each in its turn has its special departments of investigation.

The study of anatomy may be approached from the purely descriptive side, Descriptive Anatomy, or may deal with the anatomy of related organs in related animals, as Systematic Anatomy. Applied or Practical Anatomy, or that branch dealing with its study as an aid in the diagnosis and treatment of disease, may be designated as Medical or Surgical Anatomy. Regional and Topographical Anatomy deals with the study of special parts or the special relations to surrounding parts. The larger study of anatomy in its general philosophical relations to the general questions of structure is termed Philosophical or Transcendental Anatomy.

History.— The beginnings of human knowledge of the structure of organic bodies are preserved from the earliest times in fragments only, but there are very good reasons for believing that much more was known many thousands of years before the Christian era than there is written evidence to substantiate. The history of anatomical study is correlative with the history of medicine, and even in very early times inquiries were made concerning the structure of the human and animal body.

It is usual to ascribe to the Greeks the first foundations of anatomical knowledge, but it seems that Chinese culture, which was highly developed when the peoples of Europe were in a very primeval condition, had a well systematized medical lore that included much exact pharmacological knowledge, with some few anatomical facts, although the anatomy of the early Chinese was largely speculative. Section of the human as well as lower animal bodies was forbidden by at least two of the religious sects of early Chinese culture, the Alman and Buddha worships. It is interesting to note that as early as 2838–2699 B.C., Shinnong was a half-mythical medicine man in China, and it is said that Chinese works on medicine were written as early as 2698–2599 B.C. (Hwang Ai).

In India the sacred work of the Ayur Veda, supposed to date from between the 14th to the 9th centuries B.C., at least 100 years before the cult of Æsculapius had begun, contains descriptions of the human body obtained from dissections, and it may be that Charaka and Susrutu, the earliest of Indian physicians, should be considered the earliest anatomists. Egypt contributed somewhat to the knowledge of anatomy, and the Papyrus Ebers, 1553? B.C., is a monument of old Egyptian medicine. It is of interest to note that some of the Hippocratic nomenclature of anatomy is of Egyptian origin. The influence of religion, however, was very strong in the shaping of Egyptian medicine. Evisceration was largely practised and undoubtedly led to the collection of many anatomical facts the importance of which has become lost to students. It is certain, however, that the school of medicine situated in Greece, on the island of Cos, laid the firm foundations of our knowledge of anatomy. It was in Greece also that the physician's profession was amply recognized. This early Hippocratic

age gave rise to a professional conscience, and the "Physician's Oath," or the "Hippocratic Oath," "is a monument of the highest rank in the history of civilization." (Gomperz: 'Greek Thinkers.')

There were at least seven physicians with the name of Hippocrates who taught in the early times. Hippocrates II. (430 B.C.), however, was the great Hippocrates, but the knowledge of anatomy then possessed must be considered as the accumulation of the school rather than the work of any one man, for, as has already been pointed out, some of the Hippocratic nomenclature is Egyptian in origin. (v. Oefele.) Inasmuch as the Hippocratic writings are partly preserved, a better idea of the anatomical knowledge of the times may be gathered from them than from the mythical, traditional, and fragmentary remnants left by other peoples. The school of Cos had a fairly accurate and extensive knowledge of the human skeleton, and they knew the general shapes and varieties of most of the internal organs. Their physiological hypotheses, however, were crude but suggestive.

From the time of the great Hippocrates the school of Cos seemed to deteriorate, although Polybus, the son-in-law of Hippocrates II., Syennesis, Diogenes, and Praxagoras, the last named being noted for his anatomical knowledge, kept alive many of the traditions of the school. With Aristotle (384–323 B.C.) there came a period of more exact science and the dissection of the lower animals was practised, hence Aristotle may be termed the father of Comparative Anatomy. His researches in anatomy were wide and deep and his work on animals contains much that is still taught.

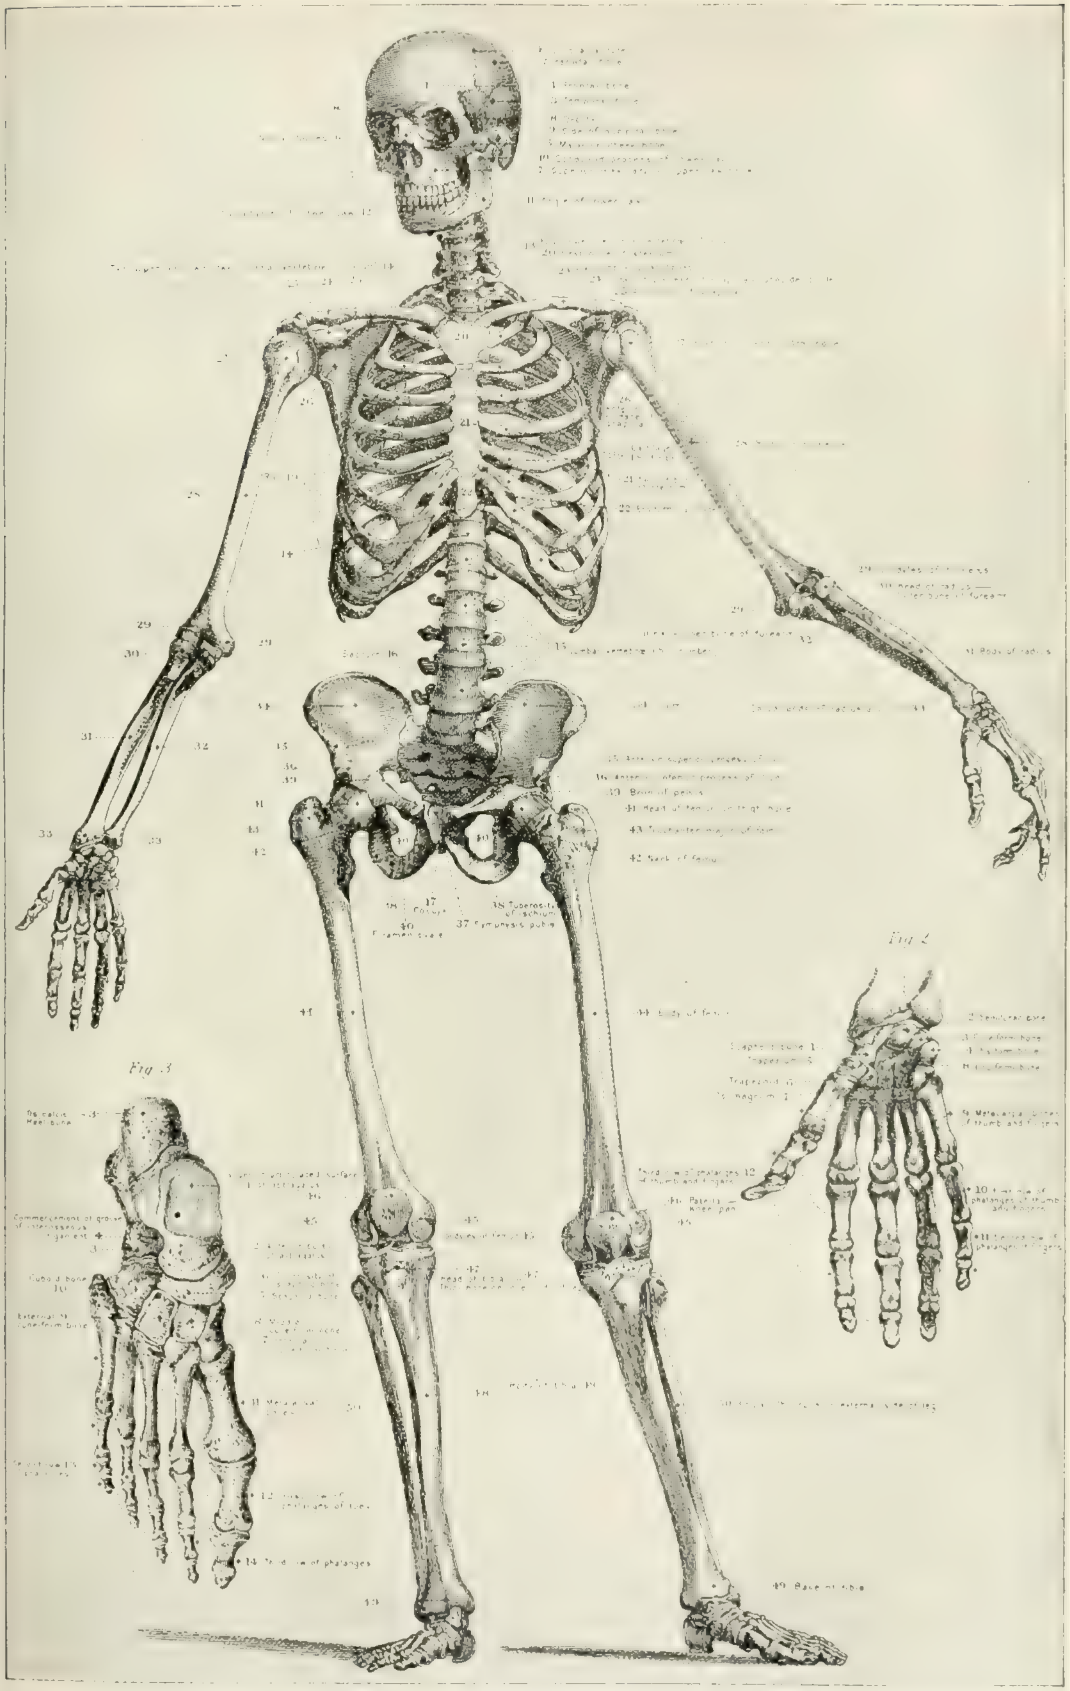
The Alexandrian period, 300 B.C., during which the culture of Rome and of Greece was encouraged in Egypt under the Ptolemies, shows as a bright spot in the history of anatomical science. With the foundation of the Alexandrian Museum, the analogue of a modern university, the practice of human dissection became authorized. This period was a brilliant one in the history of medicine. Herophilus and Erasistratus were among the early leaders, the former making some noteworthy contributions to the knowledge of the anatomy of the brain. He maintained that it was the organ of thought and the origin of motion. He also described the lacteals and the lymphatics, and was an indefatigable searcher for the seat of the soul, which he placed in the floor of the fourth ventricle of the brain, the place now known to be the site of the cranial nerves, that are indispensable for the function of breathing. Herophilus also is credited with the destruction of the old doctrine that the arteries held air, hitherto the veins only having been thought to contain blood.

Erasistratus first described the valves in the veins, made the general subdivision of sensory and motor nerves, and drew the generalization of the relation of the complexity of the brain convolutions and mental development. He also first suggested the thought of anastomoses between the arteries and veins. Many others followed, but the rise of the Empirical school (q.v.) was the forerunner of the gradual decay of the Alexandrian school. It was to the newly arisen empire of Rome that the stream had turned, and until the time of Cato Greek physicians flourished in Rome. Asclepiades (126–56 B.C.) was one of the founders of the Atomic school at Rome, and Rufus (97 B.C.) of Ephesus, with A. Cornelius Celsus (25 B.C.–40 A.D.) were among those who have left definite anatomical landmarks. Celsus is known as a brilliant man, a compiler of the work of his predecessors. His anatomical work was insignificant, but he contributed largely to therapeutics. The last dying ember of this Alexandrian transplanted school showed in Claudius Galen, a Greek from Pergamos, a town already noted for its Æsculapian temple. Galen was a man of great brilliancy, an independent thinker, and it was to his literary efforts that much of the history and treatment of the Hippocratic school has been preserved to us. His works on anatomy alone were at least fifteen in number, nine of which are preserved. Galen systematized much of the anatomical knowledge of the time, and although much of his data was drawn from the study of apes it was to pass muster in the service of human anatomy. He was perhaps the first to make any experimental physiological studies. His descriptions of the relations of the brain to the spinal cord and his knowledge of the cranial nerves were in advance of his predecessors. Galen's work stands out as the last systematic work of the Greek period, and following his death began the dark era of the barbaric inroads of the northern races and the dispersal of the culture of the East.

For a period of many centuries history is comparatively silent on the subject of medicine. No great schools arose, yet the doctrines of the ancient Greeks were kept alive in many places by obscure scholars and by many peoples, although it is known that the Saracens were largely instrumental in keeping intact that which Galen had handed down, without adding much, however, to his teachings. A flourishing intellectual development took place in the Byzantine countries, and many universities were founded by the Arabs, where the Roman-Hellenic culture was mingled with the Christian-Oriental ideas to found a new culture. Among the most famous of the Oriental physicians was Sergios von Resaina (536). He translated both Galen and Hippocrates into Syrian. Oreibasios was also a commentator of the Greeks; Avicenna (980–1036) was the Galen of the Orientals. This period of medical history has been called the Arabic period, and not until the influence of the crusades commenced to make itself felt did the period of the Renaissance begin.

The history of medicine (anatomy) now becomes more and more multiplex; new schools begin to be founded. Salerno, Naples, Montpellier, Venice, Bologna, Prague, Vienna, and Oxford successively built universities and attracted the ablest minds in medicine. Scholars traveled from university to university to learn from a professor here and a professor there, and the fortunes of the universities rose and fell like the tides of the sea. In 1224 it is said that the University of Bologna alone had 10,000 students. Among the early names of this period of transition may be mentioned Lisfranc (1295); Mondino (1275–1327), who wrote the first anatomy since the time of Galen, and which reached 25 editions,— he also suffered persecutions for his zeal in dissecting; Linacre, (1461–1524) of England, was one of the earliest scholars to bring the results of the new awaken-

ANATOMY—I. THE HUMAN SKELETON.



ing to Oxford and to Cambridge; and Sylvius, or Jacques Dubois, a Frenchman, was another of these great early anatomists of the reconstruction period. Sylvius first arranged all of the muscles of the human body and gave them the names which, for the most part, they now carry.

Andreas Vesalius (1514–1564), a Belgian, first studied at Louvain, and later became a pupil of Sylvius at Paris. At the age of 22 he became professor of anatomy at Padua, and at 29 issued a monumental work on anatomy, the best that had been given up to that time. He corrected many of Galen's errors and had a checkered career. General gross anatomy under Vesalius, who was a son, grandson, and great-grandson of a physician, began to assume more definite shape. In his student days at Paris under Sylvius, anatomy was taught upon the animal cadaver. Sylvius, however, was an uncompromising Galenist, and, although he made dissections, he followed Galen's treatises in very servile fashion. He was practically the last of his school, and his doctrines were swept away by the light thrown by this indefatigable seeker after truth as drawn from nature rather than from books. "My study of anatomy," said he, "would never have succeeded had I, when working at medicine at Paris, been willing that the viscera should be merely shown to me and to my fellow students at one or another public dissection by wholly unskilled barbers, and that in the most superficial way. I had to put my own hand to the business." Human dissection was rapidly and superficially practised, but Vesalius is known to have haunted cemeteries and gibbets to obtain human material. The results of his studies were published in 1543 in his masterpiece, 'De Humani Corporis Fabrica. Libri VII.,' the first of a long series of more distinct modern treatises on physiology as well as anatomy. Vesalius may truly be said to have been the founder of modern biological science. "He brought into anatomy the new spirit of the time, the young men of the time who listened to the new voice."

Of the contemporaries of Vesalius many were almost as famous as he. Eustachius at Rome, and Fallopius at Paris, Ferrara, and Padua corrected many of Vesalius's details, and Eustachius may be said to have been the first to call attention to the study of embryology as an aid in the interpretation of gross anatomy. Both Eustachius and Fallopius made noteworthy additions to the knowledge of the ear. These were the days of enthusiasm in the discovery of new facts, and so great was the striving for the new culture that it is said that criminals were utilized for purposes of experiment and dissection, probably after smothering. A large coterie of brilliant men lived at this time. Servetus (1509–1553), a Spaniard, first made out many of the true facts of the pulmonary circulation. Cæsalpinus (1517–1603), a highly cultured scholar and a great botanist, was among the first to speak of the circulation of the blood. Varolius (1543–1575), furthered the knowledge of the anatomy of the nervous system. Spigelius (1578–1625) made noteworthy studies of the liver. Realdo Colombo (1494–1559), who succeeded Vesalius at Padua, and was subsequently professor of anatomy at Pisa, filled out the outline of Servetus. Some authorities claim that he stole the ideas and correctly described the pulmonary circulation, although he did not appreciate the corollaries of his discovery. He imitated Vesalius and his work in a bold reproduction of his friend's studies; and Fabricius (1537–1619), who succeeded Fallopius at Padua, built a special anatomical amphitheatre where he taught anatomy to England's great anatomist Harvey.

The time had now come for a mind who could take this accumulating mass of anatomical facts, which after all were extensions in detail only of the old Hippocratic anatomy, and to discover new physiological principles, for it was noteworthy that although newer and better ideas of structure had been given, yet many of the old notions of function were still taught.

This was done by William Harvey of England. He was born in 1578, studied at many universities, mainly at Cambridge and Padua, and in 1615 first clearly demonstrated the correct action of the heart and interpreted the history of the circulation of the blood. Harvey's old anatomical preparations of this age are still in existence. From this time onward newer interpretations were possible, and the study of anatomy and physiology, now correctly linked, made rapid strides. These newer vantage grounds of interpretation were further extended by the discovery of the microscope, and by this instrument the field of microscopical anatomy, or Histology (q.v.), was opened up, leading to far-reaching and important results to the welfare of mankind. The period of detailed and special advance may be said to have been foretold in the newly revived study of physics by Borelli and his school, and the newer chemistry of Van Helmont won from the mysticisms of alchemy. These united to interpret the results of anatomical research, and the general history of the subject of anatomy widens out, fan-like, into its several specialties. The subject of anatomy now becomes lost in the history of interpretations and applications, and the further developments of these are considered in these volumes under their special heads where the developments of the various branches of anatomical research are considered. Consult ANATOMY, COMPARATIVE; ANTHROPOLOGY; BIOLOGY; CHEMICAL PHYSIOLOGY; CYTOLOGY; EMBRYOLOGY; HISTOLOGY; PATHOLOGY; PHYSIOLOGY; SURGICAL ANATOMY.

Bibliography.— The most extensive of modern works on the history of anatomy is found with complete bibliography in Neuburger and Pagel's 'Handbuch der Geschichte der Medicin,' (2 vols. 1903). See also Buck's 'Reference Handbook of the Medical Sciences' (11th ed. N. Y. 1902); Roswell Park's 'An Epitome of the History of Medicine' (1897). Of descriptive anatomies there are many: Testut and Poirier in French; Bardelben and Spalteholz in German, the latter translated by Barker into English in 1903; Morris, Quain, Gray in English; Leidy, Gerrish, and Huntington in America. The bibliography of the special subjects will be discussed in their sections. See MEDICINE, HISTORY OF.

SMITH ELY JELIFFE, M. D.,
Editor 'Journal of Nervous Diseases.'

Anatomy, Comparative, is that subdivision of the science of zoology which deals with adult forms and structures of animals with a view to determining their relationships. Comparative Anatomy and Embryology, the latter dealing

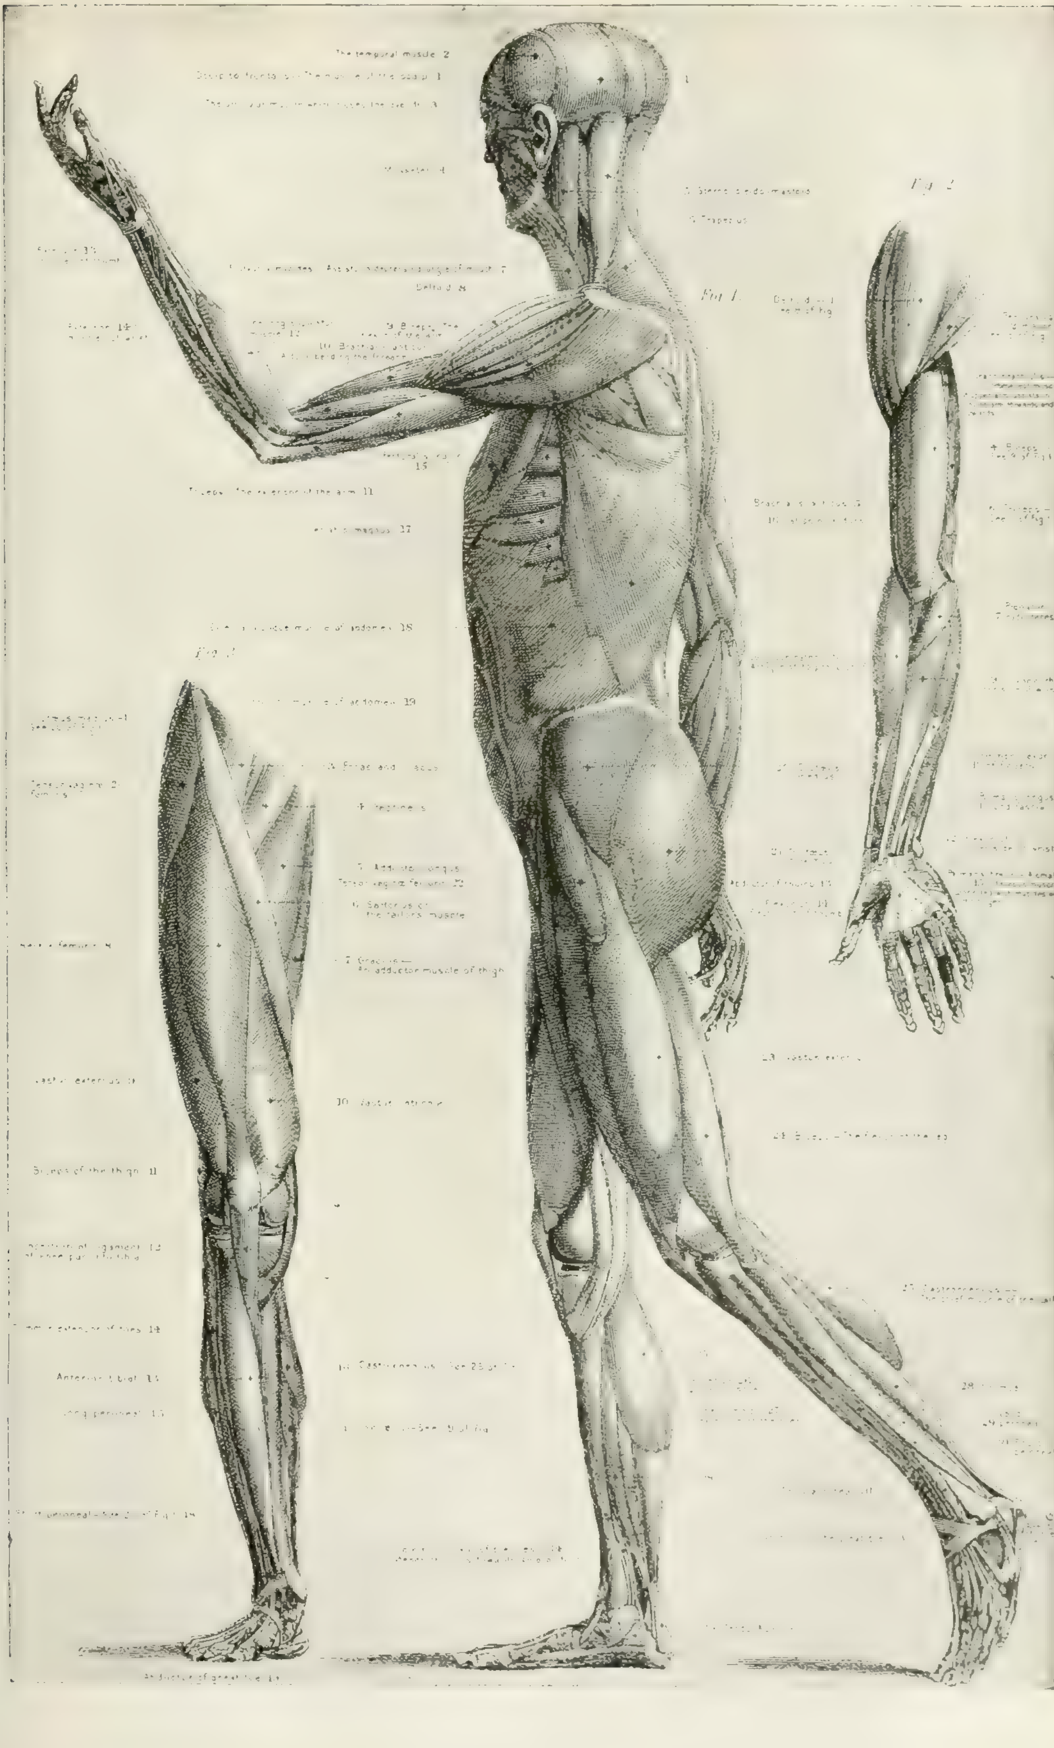
with the immature forms and structures of animals, constitute the science of Morphology, which treats of the structure, development, classification, and relationships of animals as contrasted with Physiology, which deals with their functions. In contradistinction to special anatomy, which has for its aim the description of all the structures and parts of any one animal,— for example, man,— the method of comparative anatomy is to compare corresponding parts in many different species, noting their modifications and transformations with the ultimate purpose of determining the affinities or relationships of these species to one another. In the earlier history of this science the expressions "relationship" or "affinity" were used in a metaphorical sense, signifying merely relative positions in a system of classification. With the growth of the evolution idea, however, they have acquired a new and literal meaning, since the aim of modern morphology is to determine the genetic or blood relationships of animals to one another and thereby to trace the evolution not only of the species but also of the various organs and parts. The great value of the comparative method in science is nowhere better illustrated than in the study of anatomy. There are probably not fewer than 1,000,000 known species of animals belonging to at least 10 or 12 distinct types. These animals exhibit the various organs of animal life under a great variety of forms, and bv means of comparison it is possible to determine in each case what is universal and essential and what is merely local and accidental, and also to indicate the steps by which complexity of organization has been attained. Furthermore the comparative method throws a flood of light upon the significance of problematical and rudimentary structures such as the thyroid, the thymus, and pineal glands of man, the purpose of which so puzzled the earlier anatomists. In fact it may fairly be said that it is impossible to properly comprehend any structure of the human body without considering it in relation to similar structures in other animals.

I. Principles of Comparative Anatomy.— It is obvious that in the study of animals various standards of comparison might be employed; for example, they might be compared as to color, size, or length of life, but it is at once apparent that such comparisons would bring together animals of the most diverse characteristics in other respects. As contrasted with such a purely artificial classification it was long the aim of naturalists to find a natural system expressing the "affinity" between organisms which could frequently be better felt than described. It was the great merit of Cuvier, often called the founder of comparative anatomy, that he insisted upon the importance of comparing the totality of the internal structures as well as the external characteristics of animals. By means of such comparisons he reached the conclusion that there were four great independent branches or types of animal organization, namely, *Vertebrata, Mollusca, Articulata, Radiata,* each consisting of forms fundamentally like one another but unlike those of other types. The principal criterion used by Cuvier for determining this fundamental likeness or unlikeness was the relative positions of corresponding parts, particularly of the nervous system. "The type is the relative position of parts" (Von Baer). Richard Owen, a pupil of Cuvier, introduced the term homology to describe this fundamental likeness, defining it as "morphological correspondence in the relative position and connection of parts." He contrasted with this physiological correspondence of parts, which he named analogy. In closely allied animals, organs which are homologous are usually also analogous, but in less closely related ones this may or may not be the case. Organs having the same function may be structurally very unlike, for example, the wing of a bird and that of an insect; on the other hand, organs structurally similar may have very different functions, for example, the fore leg of a quadruped and the wing of a bird. This conception of homology lies at the very foundation of all morphological studies; it is the one criterion for determining likeness or unlikeness between organisms. Owen further distinguished between special and general homology, the former signifying fundamental likeness between corresponding parts of different animals, as in the case of the arm of man and the fore limb of a quadruped; while the latter refers to similar parts of the same individual, as in the case of the fore and hind limbs of a quadruped or the right and left sides of the body. Since the term general homology as used by Owen is liable to misinterpretation it would be well to replace it by the expression meristic homology (Bateson), signifying by this term morphological correspondence between parts of the same individual which may be repeated in any relation whatever. Meristic homology would thus include correspondence between parts which are repeated in a series, for example, the vertebræ of the spinal column (serial homology, homodynamy), between parts repeated on the right and left sides of the body, for example, right and left limbs (lateral homology, homotypy) and between parts repeated in any other relations, for example, the fingers of one hand, upper and lower teeth, etc., (vertical homology, homonomy).

Significance of Homology.—To Cuvier and his followers homology meant "conformity to type," to the "archetypal plan" established by the Creator. In the light of evolution, however, homologies are believed to be family or hereditary likenesses due to inheritance from some common ancestor. For this reason special homology might better be called homogeny (Lankester) or homophyly. Contrasted with this are such morphological resemblances as are not due to inheritance, but to similarity of environment acting upon forms of dissimilar descent; such false homology is called homoplasy (Lankester), homomorphy (Gegenbaur) or convergence. It is the task of comparative anatomy to apply to animal structures these criteria of likeness or unlikeness and to distinguish between these various kinds of homology. These various forms of homology are summarized in the following table:

Homology	Special Homology (Homogeny, Homophyly)	
	General Homology (Meristic Homology)	Homodynamy (Serial)
		Homotypy (Lateral)
		Homonomy (Vertical, etc.)
	False Homology (Homoplasy, Homomorphy, Convergence)	

ANATOMY—II. THE MUSCLES OF THE HUMAN BODY.



II. General Structures and Functions of Animals.—Although the differences between the highest and the lowest animals are enormous there are nevertheless certain structures and functions which are practically the same in all animals whatsoever. All animals and plants without exception are composed of cells, while all the functions of living things are the resultants of the aggregate functions of the cells of which they are composed. The cell is thus the universal unit of organic structure and function (Cell Theory of Schleiden and Schwann), and has been defined as a mass of protoplasm enclosing a nucleus (M. Schultze). Protoplasm or living matter is a substance, usually semi-solid, of unknown but undoubtedly very complex chemical composition. It is probably composed of several complex compounds of C, H, O, and N, which do not form a mere mixture but are united in a definite and orderly way. Both the cell body and the nucleus are composed of protoplasm, though of very different quality in the two cases; that which forms the chief mass of the cell, the cell body, is called cytoplasm, while that constituting the nucleus is known as karyoplasm. At least these two kinds of protoplasm are found in every cell and are necessary to the continuance of vital activities. The cytoplasm and karyoplasm are each composed of two or more different substances of visibly different structure, and all these parts are put together in an orderly manner so that they bear definite relations to one another. The cell, therefore, no less certainly than a complex animal, shows organization,, that is, differentiation of unlike parts and integration of these parts into a single and complete whole.

As all organisms are composed of cells, so all living things have certain activities or functions in common. The most important of these are the following: (1) Metabolism, or the transformations of matter and energy within the living thing; this may be subdivided into anabolism, or the change of the matter and energy of food into the matter and energy of protoplasm; and katabolism, or the destructive changes in protoplasm by which the living matter is transformed into less complex substances (secretions, waste products, etc.), while its energy appears in various forms (heat, motion, etc.). Metabolism therefore includes nutrition, growth, waste and repair, movement, secretion, and excretion. (2) Irritability, or the capacity of receiving, transmitting, and responding to stimuli. (3) Reproduction, or the formation of new individuals from the substance of an old one. These general functions are characteristic of every living thing, plant or animal, simple or complex. From them all the functions of the most complex animal are built up, and as they are manifested in some degree by every cell it will be seen that the cell is the unit not only of organic structure but also of organic function.

All animals begin their individual existence as a single cell, but while some remain in this condition throughout life, others by repeated divisions of this initial cell become multicellular; the former constituting the group *Protozoa*, the latter the *Metazoa*. *Protozoa* are animals in which the entire body consists of a single cell, which usually leads an independent existence, though in some cases several may be united into a colony. In some forms the substance of this cell consists of protoplasm showing very little differentiation; in others it is differentiated into many unlike parts, each with its own specific function. The most general differentiation, apart from that of nucleus and cell body, is into a superficial dense layer, the ectoplasm, and a more fluid, granular interior, the endoplasm. Further specializations are shown by the more complex forms in the formation from the ectoplasm of contractile vacuoles, serving as organs of excretion; of thread-like processes, serving as organs of locomotion (*cilia, flagellæ*); of contractile fibres (myophan striations) which act like muscle fibres; of stinging threads (*trichocysts*) which serve as organs of defense; of a mouth and gullet through which food is taken into the interior of the cell, and of a calcareous or silicious skeleton, frequently of great complexity and beauty. All of these structures are differentiations of a single cell; they show how complex such a cell may become, and they indicate that the *Protozoa* are, in the words of one of the old zoologists, «perfect animals.»

In all *Metazoa* the body is composed of many cells differing among themselves in certain respects. These cells have all arisen from a single one, the egg, which by repeated divisions (cleavages) gives rise to a group of connected cells. In typical cases these become arranged in a single layer, forming a hollow sphere, the blastula, which then, by the migration of certain surface cells into the interior, becomes a two-layered sphere; the gastrula, containing a central cavity; the archenteron, or primitive digestive sack, which opens at one place to the exterior by a pore, the blastopore or primitive mouth. The outer layer of the gastrula is called the ectoderm, the inner one the endoderm, while between them a third layer, the mesoderm, usually appears, being derived from one or both of the primary layers. These three layers are known as the germ layers and from them all the organs of the adult metazoan are derived. The ectoderm gives rise to the outer covering of the body, the nervous system, and sense organs; the endoderm to the alimentary canal and its outgrowths, while from the mesoderm arise muscles, skeleton, circulatory, excretory, and reproductive systems.

In all *Metazoa* the ectoderm and endoderm and frequently also the mesoderm consist of cells, flattened, cuboid, or columnar in shape, pressed together side by side into a layer. This simplest and earliest grouping of cells in the metazoan body is called epithelium. From one or more of these epithelial layers cells may escape into the space between the ectoderm and endoderm and there become branched and irregular in shape, forming a loose grouping of cells known as mesenchyme. Epithelium and mesenchyme are the primary tissues of the metazoan body. They are the first formed in the development, and from them all other tissues are derived. The cells of one or both of these primary tissues may undergo further differentiation into contractile or muscle cells and into irritable or nerve cells, while the mesenchyme cells may give rise to non-living cell products such as fibres, spicules, cartilage, bone, and fat. When cells of any one of these groups are united they constitute a tissue, so that in the body of a metazoan we recognize, in addition to epithelial and mesen-

chymatous tissue, muscular, nervous, and sustentacular or connective tissue. Further consideration of these tissues belongs to Histology rather than to Comparative Anatomy. In all *Metazoa* two or more of these tissues may be united to form organs, which are structures of definite shape and individuality having for their purpose the carrying on of specific functions. Finally two or more organs may co-operate in a common function and are then known as an organ system. The principal systems of organs in the metazoan body are the following: (1) Integumentary; (2) Nervous; (3) Motor; (4) Skeletal; (5) Alimentary; (6) Respiratory; (7) Circulatory; (8) Excretory; (9) Reproductive.

III. Fundamental Form of the Metazoan Body.— Although the forms of multicellular animals are extremely varied they may all be referred to a single ground form, the gastrula. From the egg stage to the gastrula all *Metazoa* travel essentially the same road in their development; beyond the gastrula stage they diverge in many directions. The gastrula is therefore the latest developmental stage common to all *Metazoa* and must be taken as the ground form from which they all have been derived. It is typically a double-walled sac surrounding the archenteron or primitive digestive cavity, which opens at one pole to the exterior by the blastopore or primitive mouth. It is radially symmetrical around an axis connecting the oral and aboral poles; this is the primary or gastrular axis. In a few types — for example, sponges, hydroids, jellyfishes — this axis becomes the chief axis of the adult body; such animals constitute the group *Protaxonia*. In others (all bilateral animals) the chief axis of the adult lies almost at right angles to the gastrular axis, and it is derived in large part from one of the secondary axes of the gastrula; these forms are known as *Heteraxonia* or *Bilateralia*. Among the *Protaxonia* the adult form is radially symmetrical and differs but little from the gastrula; this is especially true of the

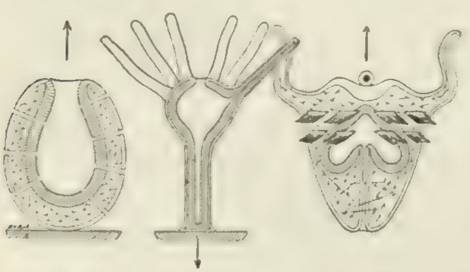


Fig. 1

Fig. 1.— Types of *Protaxonia* (= *Cœlenterata*) (from Hatschek). The chief axis of the gastrula coincides with that of the adult, the apical pole of the gastrula being indicated by the head of the arrow.— *A*, ground form of the *Spongiaria*. *B*, ground form of the *Cnidaria*. *C*, ground form of the *Ctenophora*.

hydroids, some of which are practically gastrulas throughout life which are attached by the aboral pole and with a row of tentacles around the mouth. Among the *Heteraxonia*, on the other hand, the adult shows but little if any resemblance to the gastrula from which it is derived; this is the result not only of the change of axis just mentioned but also of the complication of the gastrular layers and the formation from them of complex organs and parts. In the change of axis it usually happens that the primary axis becomes so bent that the oral and

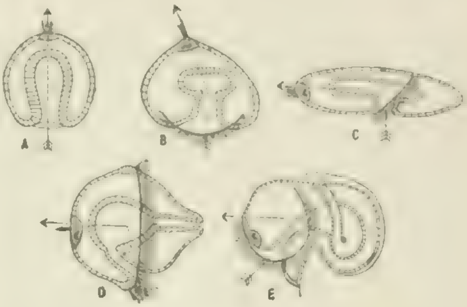

Fig. 2

Fig. 2.— Types of *Heteraxonia* (= *Bilaterata*). The gastrula axis becomes only in part the chief axis of the adult; the apical pole of the gastrula is shifted forward to the anterior end of the adult, while the oral pole of the former lies on the ventral side of the latter or near its anterior end, so that a more or less extensive bending of the gastrular axis occurs; in all cases the brain and eye arise at or near the original apical pole.— *A*, gastrula. *B*, *C*, larva and adult of flatworm. *D*, larva of annelid (trochophore). *E*, larva of gastropod (veliger).

aboral poles approach each other while at the same time one of the secondary axes elongates, becoming the principal axis of the adult, and the body becomes bilaterally symmetrical with reference to a plane passed through this axis and the original primary axis. The apical pole of the gastrula becomes the anterior pole of the adult; since brain and sense organs usually develop at this pole it might also be called the sense pole. The position of the oral pole of the gastrula with reference to the adult axis shows considerable variation in different groups, but among invertebrates it generally lies on the ventral side, while in the case of the vertebrates it is dorsal. The chief axis of the adult connects the anterior and posterior poles and is therefore known as the antero-posterior axis. The side of the body generally directed downward, and at the anterior end of which the mouth usually lies, is ventral, while the opposite side is dorsal and the line connecting these two is the dorso-ventral axis.

There are a few apparent exceptions to the rule that *Heteraxonia* are bilateral forms; some *Heteraxonia* are apparently radially symmetrical (starfish, sea-urchin), while others are asymmetrical (snails, amphioxus, flounders, etc.). The starfishes and sea-urchins are five-rayed animals which were classed by Cuvier among the *Radiata*, but a careful study of the larval as well as the adult form shows that they are really bilateral and that their radial structure has developed from a bilateral form, probably through the influence of peculiar life conditions, such as persistent attachment or fixation to foreign objects. Snails are generally spirally coiled and asymmetrical, but here also the study of their development shows that at an early stage they are bilateral, and even in the adult condi-

tion the head and ventral parts of the body are usually bilateral; the asymmetry of the dorsal part being due, perhaps, to its elongation and the shell formation covering it. In the case of other asymmetrical forms, like amphioxus, flounders, etc., it is certain that we are dealing with modifications of bilaterality due to peculiar conditions of life.

Another modification of the original metazoan ground form, the gastrula, which almost all *Metazoa* show, is due to the formation and development of a middle layer in a space, the blastocœle or primary body cavity, between the ectoderm and the endoderm, namely, the mesoderm. In the lowest *Metazoa* this consists of branched cells (mesenchyme) which are loosely packed together and contain no considerable spaces, or if present these spaces are only parts of the primary body cavity. Among the higher *Metazoa* the middle layer is usually divided into an inner portion lying next to the endoderm and an outer one next to the ectoderm. Between these two layers of mesoderm there remains a space which is the secondary body cavity or cœlom. This is lined by flattened mesoderm cells, the peritoneum, and is usually divided into right and left halves by two longitudinal partitions, the dorsal and ventral mesenteries, one of which lies dorsal to the alimentary canal and the other ventral to it; in some animals one or both of these may be destroyed. In segmented animals the cœlom may be further divided into a series of chambers by transverse partitions, the dissepiments. The excretory and sexual organs are developed in large part from the walls of the cœlom and project into its cavity. The portion of the cœlom surrounding the heart is usually separated from the remainder of this cavity and is called the pericardium; while in the highest vertebrates (mammals) the anterior portion of the cœlom which contains the lungs is separated by the diaphragm from the posterior part containing the abdominal viscera.

A further complication of the metazoan body is introduced by the repetition of the principal organs of the body in a series, one behind the other; such repetition is known as metameric segmentation, and each segment of the body is called a metamere or somite. Many of the higher *Metazoa* (annelids, arthropods, vertebrates) show this form of segmentation. In the simplest cases each of these somites has its own section of the cœlom and its own sensory, nervous, muscular, alimentary, respiratory, excretory, and sexual organs, and each may bear a pair of limbs or locomotor organs. Each somite, in short, contains all of the important organs and may properly be called a little body (somite). In more highly organized segmented animals the various segments are no longer alike (homonomous), but show physiological divisions of labor, some being differentiated for one function and some for another (heteronomous). In this way some of the organs named above disappear in certain segments while others become greatly enlarged or modified. Finally this specialization of the somites is carried one step farther in higher arthropods and in vertebrates in which we have an intimate fusion of metameres and coalescence of organs in certain regions such as to completely mask the fundamental segmentation. This is especially true of the vertebrates, the lower forms of which group show segmentation of the axial skeleton (vertebræ and ribs) and attached muscles, of the nerves, of the gills and their blood vessels, and of the excretory and sexual organs; while in the higher vertebrates (reptiles, birds, and mammals) segmentation is limited in the adult to the axial skeleton, muscles, and nerves. The fusion of somites is most pronounced at the anterior end of the body; the head of insects contains three or four somites, while the vertebrate head is composed of not fewer than nine. Among arthropods the section of the body immediately behind the head and known as the thorax is composed of a number of fused somites, while in the posterior section of the body, the abdomen, the somites do not usually coalesce. Primitively the limbs are all alike and a pair is borne on each somite; however in higher annelids and arthropods they disappear entirely from certain somites and in others undergo great modifications of structure to fit them for particular functions. In the case of vertebrates they are limited to but two pairs, and it is probable that these are derived from a continuous lateral fin by the suppression of intervening portions. The great modifications and complications which have here been briefly sketched lead far from the simple form of the gastrula, and yet comparative anatomy and embryology show that the gastrula is the ground form of all *Metazoa* and they indicate in many cases the steps by which these most complex parts have arisen.

IV. Classification.—Although there is much diversity of opinion as to the number of types

or phyla in the animal kingdom it is certain that there are more than the four recognized by Cuvier, the number being probably not less than ten or twelve. The present tendency

among zoologists is to increase this number rather than to reduce it; but the absolute separateness and independence of these types is not now generally maintained. Many of them have important characters in common, and while sufficiently distinct to mark the primary subdivisions of the animal kingdom are yet evidently related to one another. The primary divisions or phyla which are now most generally recog-

nized are the following: (1) *Protozoa*, (2) *Spongiaria*, (3) *Cnidaria*, (4) *Ctenophora*, (5) *Platyhelminthes*, (6) *Nemathelminthes*, (7) *Rotifera*, (8) *Chætognatha*, (9) *Annelida*, (10) *Arthropoda*, (11) *Molluscoida*, (12) *Mollusca*, (13) *Echinodermata*, (14) *Chordata*. Some forms cannot with certainty be assigned to any of these groups, and new phyla may need to be established for them; on the other hand future work may show that two or more of the groups named may be combined under a single phylum. The value of these phyla so far as the number and variety of animals included in them is concerned is very unequal, some of them including but a single order and but a few genera, while others include many classes, orders, and genera; in fact, about one half as many species are known in a single order of the class *Insecta* as in all the remainder of the animal kingdom put together. A tabular classification of each of these phyla and of the classes into which it is subdivided is given on the three following pages:

V. ORGAN SYSTEMS.—When two or more organs are associated in carrying on a common function they constitute an organ system. Those systems most widely represented among animals, and therefore the most important, are those concerned with the general functions of all animals, namely, metabolism, reproduction, and irritability. The first of these consists of several distinct though related functions, each with its own system of organs; accordingly we recognize the following systems: (1) digestive, (2) respiratory, (3) circulatory, (4) excretory, (5) motor, (6) reproductive, (7) nervous, (8) sensory; to these may be added those less important systems which serve for protection and support, namely, (9) integumentary, (10) skeletal. These organ systems will now be compared in broad outlines, with a view to showing their relationships in the leading phyla of the *Metazoa*. For the sake of convenience the integumentary, skeletal, and motor systems will here be considered before any of the others.

1. *Integumentary System.*—In all animals the outer covering of the body consists of a layer of epithelial cells, the ectoderm. Beneath this layer a basement membrane is present, which in some animals is thick and serves for protection and support (*Cnidaria*, *Platoda*). This epithelium is frequently ciliated and it always contains gland and sensory cells and in addition may contain nerve and muscle cells as well as stinging cells (*Cnidaria*). In some animals the epithelium, which in these cases is called hypodermis, secretes on its outer surface a cuticular covering which may be a thin and flexible membrane or cuticle (hydroids, trematodes, cestodes, annelids, rotifers), or it may be thick and flexible (nemathelminths) or dense and inflexible except at the joints (arthropods). In other cases the epithelium secretes skeletal structures in certain regions only, thus giving rise to calcareous shells (corals, mollusks, brachiopods). In arthropods this epidermal secretion is particularly dense and tough and is known as chitin; it may become calcified in certain portions. In mollusks the superficial epithelium remains naked except in a certain region, the embryonic shell-gland, where it first secretes a cuticular covering and then forms beneath this a dense calcareous layer, the shell; at the margins of the shell-gland (mantle edges) the secretion of these layers continues throughout life.

CHIEF SUBDIVISIONS OF THE ANIMAL KINGDOM.

A. PROTOZOA: One-celled animals without gastric cavity, germ layers, or tissues.

Class 1. *Rhizopoda:* With streaming protoplasmic processes (pseudopodia). Example, *Amœba.*

Class 2. *Flagellata:* With one or two vibratile protoplasmic processes (flagellæ). Example, *Monad.*

Class 3. *Ciliata:* With many vibratile protoplasmic threads (cilia) Example, *Infusoria.*

Class 4. *Sporozoa:* Parasites without mouth or organs of locomotion. Example, *Gregarina.*

B. METAZOA: Many-celled animals with gastric cavity, germ layers, and tissues.

A. PROTAXONIA (=*Cœlenterata*): *Metazoa* with gastrula-like body, persistent gastrular axis, and radial symmetry.

I. SPONGIARIA: Fixed aquatic animals with numerous pores in body wall through which water is drawn into the gastric cavity and thence expelled through a large opening, the osculum. Complicated colonies are formed by incomplete budding.

Order (1). Calcarea: With skeleton formed of calcareous spicules. Example, calcareous sponge.

Order (2). Non-calcareous: With silicious, fibrous, or gelatinous skeleton. Example, commercial sponge.

II. CNIDARIA: Aquatic animals either attached (polyps) or free-swimming (*Medusæ*) with stinging cells (cnidæ). By incomplete budding the polyps may give rise to plant-like colonies (hydroids), or by complete budding to jellyfishes (*Medusæ*).

Class 1. *Hydrozoa:* Gastric cavity without septa and without ectodermal œsophagus.

Order (1). Hydromedusæ: Usually with alternation of hydroid (asexual) and medusoid (sexual) generations. Examples, hydroids, small jellyfishes.

Order (2). Siphonophora: Floating colonies of many polymorphic zooids. Example, Portuguese man-of-war.

Class 2. *Scyphozoa:* With radial septa in gastric cavity and with ectodermal œsophagus.

Order (1). Scyphomedusæ: The solitary polyp divides into a series of jellyfishes with notched margins. Example, large jellyfishes.

Order (2). Anthozoa: The polyps divide but do not form jellyfishes. Examples, sea-anemones, corals.

III. CTENOPHORA: Two-rayed radiates with sense organ at apical pole of gastrula, with mouth and ectodermal œsophagus at opposite pole and with eight meridional rows of vibratile plates which serve as locomotor organs; without stinging cells. Example, the Venus girdle.

B. HETERAXONIA (=*Bilaterata*): Animals in which the chief axis of the adult body is not that of the gastrula; symmetry bilateral.

IV. PLATYHELMINTHES: Flatworms with mouth usually on ventral surface and with apical (sensory) pole of gastrula near anterior end of body; primary body cavity filled with mesenchyme, no true cœlom.

i. PLATODA: Gastric cavity, when present, with but one opening to the exterior, the mouth.

Class 1. *Turbellaria:* Free living forms; body covered by cilia. Example, planarians.

Class 2. *Trematoda:* Parasites without coat of cilia but with external cuticle; with suckers for attachment to host. Example, flukes.

Class 3. *Cestoda:* Parasites without mouth or alimentary canal; with external cuticle, but without cilia; usually incompletely divided into segments (proglottides). Example, tapeworms.

ii. NEMERTINEA: Free living worms with external covering of cilia; with mouth, alimentary canal, and anus; with protrusible proboscis at anterior end of body. Example, *Cerebratulus.*

V. NEMATHELMINTHES: Round worms, mostly parasitic, with long, unsegmented bodies covered by a dense cuticle; with primary body cavity; without cilia.

i. NEMATODA: Thread worms without mesenteries or peritoneum; with nerve ring around œsophagus and dorsal and ventral nerve trunks Examples, pinworms, vinegar-eels.

ii. GORDIACEA: Hair worms parasitic during part of life; with mesenteries and peritoneum; with nerve ring and ventral nerve trunk. Example, horsehair worms.

iii. ACANTHOCEPHALA: Internal parasites without alimentary canal; with proboscis and hooks for attachment to host. Example, *Echinorhynchus.*

VI. ROTIFERA: Wheel animalcules with body divisible into head (trochal disk), trunk, and tail (foot); with wheel or crown of cilia around head; with primary body cavity, and with grinding stomach (mastax). Example, wheel animalcules.

VII. CHÆTOGNATHA: Small marine worms with three body segments, namely, head, trunk, and tail; with horizontal fins around tail and on sides of trunk; with bristles (chætæ) on sides of mouth; with true cœlom (secondary body cavity). Example, arrow-worms.

VIII. ANNELIDA: Ringed worms with segmented bodies and true cœlom; the segments (somites) are typically similar (homonomous) and each encloses a section of the cœlom and of the vascular, excretory, and nervous systems.

Class 1. *Chætopoda:* Worms with bristle-like appendages (chætæ), which usually serve as organs of locomotion, on every somite. Example, earthworm.

Class 2. *Gephyrea:* Marine worms with few traces of segmentation; with crown of tentacle around mouth and with U-shaped alimentary canal, the anus opening near the mouth.

Class 3. *Hirudinea:* Worms with flattened bodies and rudimentary cœlom, without chætæ, but with anterior and posterior suckers. Example, leeches.

IX. ARTHROPODA: Animals with jointed bodies and legs; without cilia, but with the entire surface of the body covered by a coat of dense substance, chitin.

i. BRANCHIATA: Aquatic animals with gills.

Class 1. *Crustacea:* With two pairs of antennæ (feelers) and usually with gills borne on the legs. Examples, lobster, crab.

ii. TRACHEATA: Land animals with internal respiratory cavities (tracheæ, lung books).

Class 1. *Onychophora:* Worm-like animals with numerous short legs. Example, *Peripatus.*

Class 2. *Myriopoda:* Animals with head and many-jointed body, every segment bearing one or two pairs of legs. Example, centipedes.

Class 3. *Insecta:* Animals with body divisible into head, thorax, and abdomen; with four pairs of appendages on head, three pairs of walking legs on thorax, but without appendages on abdomen.

Class 4. *Arachnida:* Body divisible into cephalo-thorax and abdomen; with six pairs of appendages on former, but none on latter. Examples, scorpions, spiders.

X. MOLLUSCOIDA: Unsegmented animals, usually stalked and attached, living singly or in colonies; with a crown of ciliated tentacles around the mouth; generally with U-shaped alimentary canal and with anus opening near mouth.

Class 1. *Phoronida:* Single, stalked animals with body cavity partially divided into three portions. Example, *Phoronis.*

Class 2. *Brachiopoda:* Single animals with calcareous shell consisting of dorsal and ventral valves. Example, brachiopods.

Class 3. *Polyzoa:* Stalked animals which usually give rise to colonies by incomplete budding.

XI. MOLLUSCA: Unsegmented animals with reduced cœlom; differing greatly in form, but usually having a head, with tentacles and eyes; with a rasping organ (the lingual ribbon or radula) in the mouth; with dorsal visceral sac containing most of the viscera; with a free fold of the body wall, the mantle, which usually secretes a shell, and with a ventral muscular foot.

Class 1. *Pelecypoda:* Bivalve mollusks without head or lingual ribbon; with filiform or plate-like gills. Examples, clams, oysters.

Class 2. *Amphineura:* Bilateral animals with paired nerve trunks. Example, chitons.

Class 3. *Gasteropoda:* Unsymmetrical mollusks, with univalve shell, usually spirally coiled. Example, snails.

Class 4. *Scaphopoda:* Small mollusks with tubular, uncoiled shells. Example, *Dentalium*.

Class 5. *Cephalopoda:* Active, predaceous mollusks with unpaired mantle and shell and with eight or ten arms which bear suckers. Example, squid octopus.

XII. ECHINODERMATA: Five-rayed marine animals, with dermal skeleton of spines or plate; with ambulacral system of tubes which are filled with sea-water.

Class 1. *Holothuroidea:* Soft, worm-like animals with reduced skeleton; the mouth surrounded by retractile tentacles. Example, sea-cucumbers.

Class 2. *Echinoidea:* Spherical or oval forms with complete armor of dermal plates. Example, sea-urchins.

Class 3. *Asteroidea:* With five arms radiating from a central disk; with open ambulacral grooves on the oral side of arms. Example, starfishes.

Class 4. *Ophiuroidea:* With arms and central disk, but with closed ambulacral grooves. Example, brittle stars.

Class 5. *Crinoidea:* The cup-shaped body bearing many branching arms is usually attached by a stem. Example, stone-lilies.

XIII. CHORDATA: Bilateral, segmented animals with an axial skeleton, the notochord, on the dorsal side of which is the tubular nervous system and on the ventral side the alimentary canal; with gill slits opening laterally through the walls of the pharynx.

i. HEMICHORDA: Worm-like animals which burrow in the sand. Example, *Balanoglossus*.

ii. UROCHORDA: Sac-like animals enclosed in thick tunic (*Tunicata*) in which are inhalent and exhalent openings. Example, sea-squirts.

iii. CEPHALOCHORDA: Fish-like animals, pointed at both ends, which burrow in the sand; without skull or brain (*Acrania*). Example, *Amphioxus*.

iv. VERTEBRATA: Chordates with skull and brain; with relatively few gill slits; the notochord serves as a foundation for the vertebral column; usually with two pairs of locomotor appendages.

(a). **Anamnia:** Aquatic vertebrates with functional gills; without embryonic membranes.

Class 1. *Cyclostomata:* Eel-like fishes without jaws, but with circular sucking mouths; with single olfactory organ; without paired fins. Example, lamprey.

Class 2. *Pisces:* Cartilaginous and bony fishes with movable jaws, persistent gill clefts, paired and median fins, and dermal exoskeleton of scales. Examples, sharks, fishes.

Class 3. *Amphibia:* Vertebrates with pentadactyl limbs with gills and gill clefts in larval life which may be lost in the adult. Examples, frogs, newts.

(b). **Amniota:** Air-breathing vertebrates in which the gills are never functional; the embryo is always surrounded by embryonic membranes (amnion and allantois).

Class 4. *Reptilia:* Body covered by horny scales or plates; heart usually three-chambered; one occipital condyle. Examples, snakes, alligators.

Class 5. *Aves:* Birds with body covered with feathers and usually fitted for flight; with four-chambered heart and single occipital condyle. Examples, sparrow, pigeon.

Class 6. *Mammalia:* Animals with the body covered with hair; with mammary glands for suckling the young; with four-chambered heart and with two occipital condyles. Examples, dog, horse, man.

In reptiles, birds, and mammals the superficial epithelium (epidermis) becomes many layers thick, and the outer layers of cells die and are transformed into horny or cuticular substance; an adaptation to life out of water. In these three classes of vertebrates there are also a number of characteristic epidermal outgrowths: in reptiles these take the form of horny scales or plates; in birds they appear as feathers, which are only modified scales; and in mammals as hair, while nails or claws are formed from the epidermis in all of these classes. In the mammals there are also epidermal ingrowths which give rise to various types of glands, such as sweat, oil, wax, and milk glands, all of which are epidermal in origin.

Beneath the surface epithelium, which is always ectodermal in origin, there is in many animals a fibrous or connective tissue layer known as the dermis or corium. This layer is especially well developed among echinoderms and vertebrates, in both of which it may give rise to skeletal spicules or plates, thus forming a dermal exoskeleton. Among the vertebrates this is especially well developed in the fishes, the scales which cover the body being of dermal origin; in some cases these dermal scales are covered by enamel which is derived from the epidermis. The same is also true of the teeth of vertebrates; the inner portion or dentine is of dermal origin, while the enamel comes from the epidermis; teeth are in fact only modified scales.

2. *Skeleton.*— An internal skeleton, not the product of the integument, is present in relatively few invertebrates, but is found in all vertebrates. Such a skeleton is found in sponges in the form of calcareous, silicious, or horny spicules; in cnidarians and ctenophores as supporting jelly; in many invertebrates as a system of connective tissue cells and fibres; in cephalopods and certain arthropods as cartilages surrounding the central nervous system. On the other hand the possession of a primitive axial skeleton, the notochord, is one of the chief characteristics of the *Chordata;* in addition to this there are generally present in this phylum many other skeletal elements which are usually cartilaginous or bony. In all true vertebrates the notochord becomes surrounded by cartilage, and the whole is then constricted into a series of segments, the centra of the vertebræ; from these centra cartilaginous arches grow dorsally around the spinal cord, while other skeletal arches, the ribs, surround the trunk and become connected with the vertebral column; finally the ribs may be united ventrally, thus forming the sternum: these parts constitute the axial skeleton. In addition there is the skeleton of the head (the skull) and that of the limbs (the appendicular skeleton). In the lower vertebrates and in the embryos of all higher forms the skull consists of a cartilaginous cranium partially surrounding the brain, and of paired cartilaginous rods forming the skeleton of the jaws and gill-arches. In higher vertebrates these cartilaginous elements undergo ossification, and in addition dermal bones are formed which partially overlie this cartilaginous basis. The appendicular skeleton consists of the two limb-girdles partially enclosing the trunk on the ventral side, the pectoral and pelvic arches, and of the skeleton of the limbs themselves. In the fishes the arches and limbs are peculiar and it is difficult to homologize their skeletal parts with those of higher forms; in all vertebrates above the fishes, however, the relations of these parts are similar and their homologies not difficult to determine.

3. *Motor System.*— All animals at some time in their lives have the power of locomotion, though in some cases this is lost before adult life is reached and the animal becomes fixed like a plant (hydroids, sponges, crinoids, molluscoids, and many parasites). However, in all these cases certain parts of the body preserve the power of movement, though the animal as a whole is incapable of locomotion. Animal movement is of three fundamental types: amœboid, ciliary, and muscular. See MUSCLES.

(1) Amœboid movement is manifested especially by free cells and exhibits a streaming of semi-fluid protoplasm: it is typically illustrated by the proteus animalcule *Amœba.* In this protozoan small lobes or pseudopodia may appear anywhere on the body, and into one or more of these the endoplasm, with all that it contains, may be seen to stream, at the same time being withdrawn from other lobes. This flowing may continue for some time in a given direction, the outflow of protoplasm at one end of the body being compensated for by the inflow at the other end, thus producing an actively progressive movement. The mechanism of this movement is obscure, but in some cases it seems to be associated with temporary inequalities in the tension of the surface of the cell; at points where the surface tension is reduced an outflow of protoplasm occurs, forming a lobe or pseudopod, into which protoplasm from the main body continues to flow so long as the surface tension is least in this direction. Usually several points of reduced tension exist at the same time on the surface of an amœboid cell, so that several lobes or pseudopodia are found radiating from a common centre. In other cases it is, perhaps, due to the general contractility of protoplasm, local contraction in one part of a cell causing an outflow in another part.

(2) Ciliary movement consists in the rhythmical beating of innumerable small protoplasmic threads (cilia) which project from the free surfaces of certain cells and which act somewhat like oars. Among one-celled organisms the entire cell may be covered by these cilia; in all multicellular animals they are limited to the free borders of certain epithelial cells. The beating of a cilium includes two movements, — the stroke, which is rapid and by which the cilium is sharply bent in one direction, and the recovery of the original position, which is relatively slow and weak. It is probable that the cause of this beating is the unequal contraction of the protoplasm on different sides of a cilium, by which it is bent first in one direction and then in the other. All the cilia covering a free surface beat in unison, the stroke being in one direction, and the movement is so timed that beginning at one end of a ciliated tract it seems to pass in a wave-like movement to the other end.

(3) Muscular movement, the principal type of motion in higher animals, is caused by the contraction in one direction of a muscle fibre consisting of a kind of protoplasm especially differentiated for this purpose. During the contraction or expansion of a muscle there is no change in its volume, the shortening of a fibre in one

axis being compensated for by its expansion at right angles to that axis. Such a change in the shape of a fibre could be produced only by a change in the shape of the particles of which it is composed or by a change in their relative positions. The latter is probably the real cause of muscular contractility.

All of these types of movement are found in certain *Protozoa* and in many *Metazoa*. Amœboid movements are, however, usually restricted to free cells without membranes or dense cortical layers of protoplasm, such as certain egg cells, embryonic cells, endoderm cells, excretory, pigment, and lymph cells of various *Metazoa;* in no case is this type effective in the movement of large bodies. In the larvæ of all phyla, except the nemathelminthes and arthropods, locomotion is brought about, at least in part, by cilia, and even among the adult forms of many lower metazoans this is the principal type of locomotion (ctenophores, turbellarians, nemertines, rotifers). Among the nemathelminths and arthropods cilia are entirely lacking throughout the whole life cycle. Among large animals locomotion is effected entirely by muscular contractility, while cilia are limited to certain regions where by their beating they produce currents. Muscle fibres are found in all *Metazoa* with the possible exception of sponges; they are of two kinds, striped and non-striped or smooth; the latter are of very wide distribution throughout the *Metazoa*, the former are limited to a few phyla (mollusks, arthropods, chordates). Smooth muscle is contractile to a much greater extent than striped muscle, but is much slower in action. The muscular system may consist of isolated fibres such as are found in many cnidarians, platodes, and rotifers, or these fibres may be united into bundles or sheets as is the case in most higher animals; these groups of muscles show many differences and can be compared only in a general way. In general the arrangement of the body muscles depends upon the presence or absence of a skeleton. Animals which have no skeleton usually have the body musculature arranged in the form of two coats: an outer layer of circular fibres and an inner of longitudinal ones, while the intestinal musculature is also arranged in two coats, the outer (next the cœlom) longitudinal and the inner circular. If an exoskeleton is present, as in arthropods, these muscular layers of the body wall are broken up into bundles which become attached to the skeleton; if an endoskeleton is present, as in vertebrates, the muscles become attached to the bones, which serve as levers, and thus the muscles come to lie at a deep level. The locomotor apparatus of echinoderms is unique, consisting of a great number of tube feet, which are hollow muscular tubes, closed at the end by a sucking disk. The cavity of each tube is connected with the water vascular (ambulacral) system within the body, from which water can be forced into the tube feet. In this way they are protruded until the sucking disk touches and becomes attached to some object; then by contraction of the muscles of the foot the water is forced back into the water system, and by simultaneous action of many of these feet the body is slowly warped along.

4. *Digestive System.*— With the exception of a few internal parasites which absorb their food in a digested condition from the bodies of their hosts, some form of digestive system is present in all animals.

Digestion is the process of rendering insoluble foods soluble. One of the distinguishing characteristics of animals is that they, unlike plants, take in solid food (much of which is in an insoluble condition) through a mouth opening (ingestion), and that by the process of digestion some of this insoluble food is rendered soluble and hence capable of diffusing to all parts of the organism, where by a mysterious process known as assimilation some of it is built up into the substance of the protoplasm itself. After the substances rendered soluble by digestion have been removed from the food the indigestible remnants are cast out of the body in solid form (egestion). Among the *Protozoa* digestion occurs within the body of a single cell, that is, it is intracellular. The same is true of the sponges, in which the food, consisting of microscopic animals or plants, is taken in by certain epithelial cells lining the cavities of the the sponge and by them passed over to other cells and tissues by which the food particles are ingested, digested, and assimilated. In all animals above the sponges intracellular digestion is limited to the endoderm cells and to certain free cells, such as white blood corpuscles (leucocytes) and it is of decreasing importance as one ascends the scale. In all animals except the lowest, digestion occurs principally in a digestive cavity surrounded by cells which pour their secretions into the cavity. By the action of these secretions certain insoluble food substances are transformed into soluble ones. This digestive cavity is in all cases derived from the archenteron or primitive digestive cavity of the gastrula and in the simplest cases is little more than a sac whose walls may be folded into ridges or septa, thus enlarging the digestive surface (*Anthozoa*), or they may be extended to form tubular canals, by means of which the digested food is distributed to all parts of the animal (*Scyphozoa, Ctenophora, Turbellaria*). In all *Cnidaria* except the lowest class, and in all animals above the *Cnidaria*, the ectoderm surrounding the mouth is folded in at the mouth opening, thus forming an ectodermal tube, or œsophagus, which opens at the inner end into the gastric cavity. Among chordates this ectodermal invagination forms only the mouth cavity, the œsophagus being derived from the endoderm. In all *Cnidaria, Ctenophora*, and *Platoda* there is but one opening into the gastric cavity, the mouth, and through this single opening food is taken in and undigested remnants cast out. In the *Nemertinea*, and with a few exceptions in all higher animals, there is a second opening into the gastric cavity, namely, the anus, through which the ejecta pass. The anus is formed by an infolding of the ectoderm which meets and fuses with a portion of the gastric wall; this terminal ectodermal portion of the digestive tract is the hind gut. With the formation of an anus the digestive tract becomes tubular, with mouth at one end and anus at the other, and the entire canal is divisible into three portions, an ectodermal œsophagus or fore gut, an endodermal mid gut and an ectodermal hind gut. The relative development of these three portions differs much in different phyla; for example, among chordates the fore gut is limited to the mouth cavity and the hind gut to an in-

significant terminal portion of the intestine, while the mid gut gives rise to all the intervening portions of the digestive tract. Among arthropods, on the other hand, the mid gut is limited to an extremely small portion of the digestive tube between the stomach and intestine, while all the remaining portions are derived from the fore and hind guts. In the higher animals the fore and mid guts may be subdivided into mouth cavity, pharynx, œsophagus, stomach, and intestine and in some cases these portions may be further subdivided, as, for example, in birds, where the œsophagus gives rise to an enlargement, the crop, the stomach is divisible into a glandular stomach and a grinding stomach or gizzard, and the intestine consists of two portions, the small and the large intestine. Finally into a portion of the hind gut the excretory and sexual ducts as well as the intestine may open, in which case this common chamber is called the cloaca. Various portions of the fore gut may be armed with teeth, usually of a horny character among invertebrates, and the pharynx may be protrusible. The digestive and absorptive surfaces of the mid gut may be increased in three different ways, either (1) by an increase in length, in which case it becomes folded or coiled, or (2) by folds which project into the canal, or (3) by diverticula, that is, blind sacs or tubes, which open out from the canal; in many higher forms all of these methods coexist in the same individual. The extent of the digestive surface depends primarily upon the character of the food; if the latter is highly nutritious the digestive surfaces are much smaller than where it is poor in nutrition. In carnivorous mammals, for example, the alimentary tract is from four to five times the length of the body, whereas in certain herbivora it may be from 20 to 30 times the length of the body. In the simplest *Metazoa* it is probable that all the cells lining the digestive cavity are alike and that they all secrete the same digestive fluids; in more complex animals the cells differ in structure and function in different portions of the tract. By a specialization of the diverticula or blind tubes opening out from the canal, large digestive glands are formed which pour particular digestive secretion into the alimentary canal. The most generally distributed of all these are the salivary glands, opening into the fore gut, and the liver and pancreas (or where both are united, as often happens among the invertebrates, the hepatopancreas), which open into the mid gut. In all of the lower invertebrates except the roundworms the food is moved about in the alimentary tract by means of cilia or by general contractions of the body. In all higher forms the contraction of muscle fibres surrounding the canal play an important part in this movement, though cilia may also be present. In the chordates both longitudinal and circular muscles surround the canal and by their rhythmical contractions produce a wave-like contraction of the canal (*peristalsis*), which passes along the canal from mouth to anus.

5. *Respiratory System.*— Respiration consists in the exchange of gases between the body and the medium which surrounds it. The gas given off from the body is principally carbon dioxid, one of the products of combustion within the body, while that which must be supplied to it is oxygen. Since oxidation is the one essential feature of destructive metabolism which occurs in all living matter, it follows that respiration is a universal function among organisms. Among small and simple animals this exchange of gases takes place directly between the living cells and the surrounding medium and occurs all over the surface of the body. In more complex forms with body fluids the exchange takes place between the tissues and the fluid (internal respiration) and then between the fluid and the surrounding medium (external respiration). This exchange may take place through the general integument of the body without the aid of any specific organs, as is the case in all small animals and in many larger ones,— for example, flatworms, roundworms, rotifers, small annelids, and even some vertebrates, such as the lungless salamanders. However, in most animals of any considerable size, special organs exist to facilitate this exchange. In such as dwell in water vascular processes are present which serve to bring the blood into close relation with the water. These processes, which are called branchiæ or gills, are covered by a thin epithelium through which an interchange of the gases contained in the blood and in the water can readily take place. To facilitate this interchange the gills are usually much folded or branched so as to afford a large

surface, and they are frequently covered by cilia which serve to keep the water in motion, while at the same time the blood is circulated through them. The most primitive type of gill is that of a simple ciliated tentacle, which may also serve other functions, such as is found among the *Molluscoida* and some *Mollusca;* such gills may become branched or plume-like or may fuse together into plates (*Lamellibranchia*). Gills are situated on those parts of the body where

they will be most exposed to fresh water, and occur in the most extraordinarily different positions in different phyla; thus they may be found on the limbs (*Crustaceæ*, some annelids), on or around the head (sedentary annelids, molluscoids), along the sides of the body (primitive mollusks), on the lateral walls of the pharynx (chordates), or as outgrowths of the hind gut (holothurians). Homology being «correspondence in the relative position and connection of parts,» there can of course be no homology between structures occurring in such diverse positions, and yet within a given phylum they may be homologous and of high morphological value (for example, chordates). Among the chordates a series of gill-clefts opens right and left through the walls of the pharynx, and in the lower classes of the phylum the gills are found as highly vascular plates or tufts on the outer sides of the arches separating these clefts; water is taken in through the mouth and then forced out through the gill-clefts and thus over the gills. In the higher classes of the phylum (reptiles, birds, and mammals), the gill-clefts are present during embryonic life, though at no time in their entire life-history do these animals have gills and respire water. The constancy of gill-clefts among vertebrates gives this character a high value in determining the affinities of such doubtful forms as *Balanoglossus*, *Cephalodiscus*, and *Tunicata*.

In animals which do not dwell in water and in some few which do (insect larvæ, lung fishes, etc.), certain infolded portions of the body occur into which air is drawn and from which it is again expelled. Among invertebrates these infolded portions are generally derived from the skin; among vertebrates from a portion of the alimentary canal, the pharynx. In the case of insects and allied forms (*Tracheata*) these infolded portions have the form of much-branched tubes, the tracheæ, which reach to all parts of the body, the terminal twigs of the tracheal system of tubes being found in connection with almost every bit of tissue in the body. These tracheæ open to the exterior through closeable pores, the stigmata, situated on the sides of the body; air is taken in through these pores and by means of the tracheal tubes penetrates to all parts of the body, the exchange of gases taking place directly between the tissues and the tracheæ. Among the vertebrates the lungs are an evaginated portion of the pharynx, which in most fishes is a hydrostatic apparatus, the swim-bladder, but which in the lung fishes (*Dipnoi*) becomes highly vascular and may serve as a lung. In all higher vertebrates this sac is paired, and its walls, which in the lower classes are relatively simple, become much infolded and very richly supplied with blood vessels. The exchange of gases here takes place between the blood and the air within the lung, and in most vertebrates the oxygen-carrying capacity of the blood is increased by the presence of hæmoglobin (the coloring matter of red blood corpuscles) which enters into a loose chemical combination with the oxygen.

6. *Circulatory System.*— The physiological significance of the circulation of fluids within the body is the distribution of nutriment and in some cases oxygen to all the parts. In the simplest *Metazoa* (*Cnidaria*, *Ctenophora*) there is no need of a special circulatory apparatus other than that which is furnished by the gastric cavity itself; this may branch and extend to various parts of the body or hydroid colony, thus forming a gastro-vascular system, through which the distribution of nutriment takes place; the branched gastric cavity of certain turbellarians serves also a similar function. Circulation of body fluids also occurs in many lower animals without the aid of any special circulatory apparatus; in such cases lymph, containing the products of digestion, is distributed through all the intercellular spaces in the primary body cavity, and by the contractions of the general musculature of the body it is kept in irregular movement. With the single exception of the nemerteans a blood vascular system is found only among animals with a secondary body cavity or true cœlom and is lacking even in some of these, particularly such as are quite small or are evidently degenerate forms. With a few exceptions it is present in mollusks, echinoderms, annelids, arthropods, and all chordates. In its simplest form it consists of branching and anastomosing tubes which contain blood. The walls of the tubes are composed of flattened epithelial cells (endothelium) which may be surrounded on the outside by muscle or connective tissue fibres. The blood which fills these vessels consists of a fluid or plasma within which floating cells or corpuscles are almost invariably present. With increasing complexity of this system the walls of the vessels become thicker by increase of the muscular or connective tissue coats, and in certain parts of the system the vessels become larger. The muscular walls may be pulsatile throughout the entire length of a vessel, or this function may be limited to a small portion of a large vessel, which is then known as a heart; even in the highest animals the heart is only a differentiation of a simple pulsatile blood vessel. The vessels leading away from the heart are the arteries, those through which the blood flows back to the heart the veins, while the small thin-walled vessels connecting the two, and through the walls of which plasma escapes

into the tissues, are the capillaries. Among the annelids there is a large dorsal vessel and a ventral one, which are connected in each somite by commissural vessels. The dorsal vessel is pulsatile along its whole length, and peristaltic contraction waves can be seen in a living worm

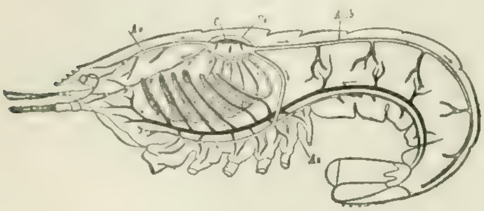

Fig. 12

Fig. 12.— Circulatory and respiratory systems of the crayfish (from Claus).— *C*, heart with three pairs of ostia; *Ps*. pericardium; *Ac*, cephalic aorta; *A. ab*, abdominal aorta; *As*, sternal artery. The arrows indicate the direction of the flow.

to pass from the posterior to the anterior end; correspondingly the blood flows forward in the dorsal vessel, down through the commissural vessels into the ventral one, and then backward through the latter to the posterior portion of the body, where the blood ascends through commissural vessels to the dorsal vessel, after which the same circuit is repeated. Throughout this whole course the blood flows through vessels with definite walls, and the circulation is said to be closed. Among the mollusks and arthropods a heart is present which is more concentrated and complete than among the annelids. In the arthropods this consists of a thick-walled, pulsatile tube lying on the dorsal side of the body and extending through several somites; in each somite are a pair of openings, the ostia, which open into the heart from the pericardium, and through which returning blood enters the heart. Among the mollusks the heart is also of a compact type and is divided into auricular and ventricular portions. Primitively two auricles are present, though in some gasteropods this number is reduced to one; in all mollusks there is but one ventricle. In primitive arthropods and mollusks the blood flows out of the ventricle at both the anterior and posterior ends; in more highly differentiated members of these phyla, out of the anterior end only. Among the arthropods the vascular system is very incomplete, the arteries soon end in lacunar spaces in the tissues, and from these spaces the blood is gathered into large sinuses and thence flows back to the heart. These lacunar spaces and sinuses are not true vessels, since they do not have definite walls, but are derived from the primary and secondary body cavities; the circulation is therefore an open one. Among mollusks the vascular system is more extensive than among arthropods, but here also the circulation is open, the arteries being connected with the veins by a system of lacunar spaces instead of capillaries. Finally among the echinoderms and chordates the circulation is closed as among the annelids; that is, the blood throughout its entire circuit is contained within definite vessels.

The manner in which blood is supplied to the respiratory organs is of great importance in explaining the structure of the circulatory organs in air-breathing vertebrates. Among annelids, arthropods, and mollusks the blood flows directly from the heart to all parts of the body, whence it is gathered into trunks which carry it to the gills; from these organs it is then returned purified to the heart. In the fishes the blood passes from the heart directly to the gills, whence it is gathered into the dorsal aorta and distributed to all parts of the body; it is then returned laden with waste product from the tissues to the heart. In these animals the heart consists of a single auricle and ventricle, essentially a simple tube more or less bent upon itself. In air-breathing amphibia a part of the blood passes directly from the heart to the lungs, whence it returns to the heart oxygenated, while a part of it goes at once to the body; the former is known as the pulmonary, the latter as the systemic circulation. In these animals the heart is incompletely divided by a partition which separates the auricular chamber into two auricles, but which leaves the ventricle undivided. The blood returning from the body is carried into the right auricle, while that from the lungs goes into the left; in the ventricle both kinds of blood mingle to a certain extent, though by a peculiar arrangement of folds and valves the larger part of the oxygenated blood which enters the left auricle is pumped to the anterior part of the body, while the blood from the right auricle goes to the lungs and to the posterior

parts of the body. Finally in all birds and mammals and in the highest reptiles (*Crocodilia*) the heart is completely divided by a partition into two auricles and two ventricles, and a double circulation, systemic and pulmonary, is established. The blood from the left ventricle goes

at once to all parts of the body, whence it returns to the right auricle; it then falls into the right ventricle and is pumped from that to the lungs; here it is oxygenated and returns to the left auricle, and then from the left ventricle is again sent out to all parts of the body.

7. *Excretory System.*— Excretion is the process of removing non-gaseous waste products, particularly urea and allied compounds, from the body. These nitrogenous waste substances are formed as the result of proteid combustion within the body, and as this form of metabolism is universal among animals nitrogenous waste substances are everywhere formed. With few exceptions all animals possess some form of excretory organ; in fact this is one of the distinguishing characteristics of animals as contrasted with plants. Among the *Protozoa* the excretory organ is a pulsatile vacuole which gradually fills with fluid containing these waste products and then suddenly contracts, forcing this fluid out of the body. Among cœlenterates excretion is probably performed by isolated gland cells, so that no single organ exists for this function; even among higher animals excretion is performed to a limited extent by individual cells or small glands; for example, the chlorogogue cells of annelids, the dermal glands of *Crustacea*, and the sweat-glands of mammals. In all higher animals a special excretory organ exists; this usually consists of minute tubules formed of cells which take up the waste substances and pass them into the tubule, whence they are carried to the exterior; such an excretory tubule is known by the general name of nephridium. The forms of nephridia differ considerably in different phyla, but two principal types may be recognized; these are the protonephridium, or water vascular system, and the metanephridium (Hatschek). The protonephridium is found in the flat worms and rotifers; that is, among worm-like animals with-

FIG. 16

FIG. 16.— Structure of the protonephridium (excretory organ) of a flatworm (from Hatschek).—*A*, part of the excretory apparatus of a tapeworm; R, edge of body; C, collecting tubules.— *B*. Terminal cells with flame of cilia.— *C*. Diagram of terminal cell, excretory capillary, and canal.

out a secondary body cavity; it is also found as the larval excretory organ (head kidney) in annelids. It consists of a pair of more or less branched tubules opening at one or more places to the exterior, while the internal terminations of the tubules each end in a single large cell which closes the end of the tubule and bears a tuft of long cilia projecting into its lumen. This tuft beats with undulatory movement and looks somewhat like the flickering flame of a candle, whence it is called a "flame" and the large cell which bears it a "flame cell." The tubule itself is usually composed of a single series of long glandular cells so perforated

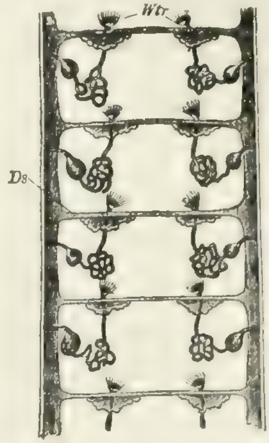

FIG. 17

FIG. 18

FIGS. 17, 18.— Diagrams of the excretory system in an annelid and in a shark (from Claus after Semper). —*Ds*, dissepiments; *Wtr*, ciliated funnels; *Ug*, segmental duct.

that the lumen is intracellular. In larger branches of the protonephridium the walls of the tubule may be formed of many cells which are ciliated on the side next the lumen. These cilia as well as the flame drive fluids within the lumen to the exterior. It is probable that these fluids are transuded body fluids and that the excretion of the waste substances is brought about by the activity of the cells which form the walls of the lumen.

The metanephridium is found among annelids, mollusks, molluscoids, prototracheates, and chordates, while a modified form of it exists in crustaceans. Typically it consists of a tubule opening to the exterior at one end and into the body cavity or some portion of it (pericardium or blood sinus) at the other. Where it opens into the body cavity the tubule is widened and covered with long cilia and is known as the ciliated funnel or nephrostome. Following this is the glandular portion of the tubule, consisting of a single series of perforated cells, or in other cases of an epithelium, composed of many cells, which forms the walls of the lumen. In either case these cells are glandular in character and are the real excretory cells, taking urea from the blood and passing it into the lumen of the tubule. The latter is ciliated throughout, and by the action of these cilia, together with those of the ciliated funnel, cœlomic fluid is drawn into the tubule through the funnel and driven to the exterior, thus flushing the tubule and carrying away the excreted substances. Finally the terminal portion of the tubule, which is derived as an invagination from the ectoderm, serves as a collecting tube or reservoir. Generally a single pair of these tubules is found in unsegmented animals, such as *Mollusca* and *Molluscoidea*; this number may be reduced,

however, as in the *Polyzoa*, where they are entirely lacking, or in certain *Gasteropoda*, where one of them is suppressed, or it may be increased as in the case of certain *Cephalopoda* (*Tetrabranchia*), where two pairs are present. In segmented animals, such as annelids, prototracheates, and chordates, it is probable that originally one pair existed in every somite, and this is still approximately the case in some of the simplest members of these phyla, while in higher forms they are limited to certain segments and have disappeared from others. The segmental character of these organs is so characteristic in the phyla named that they are called "segmental organs."

Among the *Chordata* these organs undergo modifications which deserve especial mention. They lie at the dorsal side of the body cavity and on each side of the notochord. Only in *Amphioxus* do they open individually to the exterior; in other chordates the peripheral ends of the tubules unite on each side into a duct which grows backward and opens into the cloaca near the anus; this is the segmental duct. This earliest system of segmental tubules in chordates is known as the pronephros, and it extends throughout the entire trunk region of the lowest vertebrates (cyclostomes), though in all higher forms it is limited to a few anterior somites and is usually a purely embryonic organ. Among these higher forms longer and more complicated tubules are formed in the somites behind the pronephros, which also open into the segmental duct at one end and into the body cavity at the other; near the ciliated funnel a knot of blood vessels forms on the side of the tubule and projects into its lumen; this is the glomerulus or malpighian corpuscle. Many of the tubules in this region then lose their ciliated funnels and no longer open into the body cavity, the tubule being flushed out by transuded plasma from the glomerulus; at the same time the single pair of tubules originally present in each somite may give rise to others by budding, so that several may be found in each somite. This second form of the nephridial system of vertebrates is known as the mesonephros, and is the permanent excretory organ of fishes and amphibians, while only an embryonic organ in reptiles, birds, and mammals. Finally, in the last named classes, the definitive kidney or metanephros appears in several of the somites posterior to the mesonephros. Its tubules, while similar to those of the mesonephros, are still more complex, having no trace of a ciliated funnel, and by budding very many of them are formed in each somite. The duct into which they open, the ureter, is an outgrowth of the segmental duct. It is thus to be seen that the very complex excretory system of vertebrates can be derived, step by step, from the simple nephridial system of such invertebrates as the annelids.

Finally, the nephridia may carry off from the body cavity not only cœlomic fluid, but also cells which are set free into this fluid; some of these cells in the annelids may be loaded with urates which are thus carried to the exterior (chlorogogue cells), but the most important of the cells which thus escape from the cœlom are the sex cells, ova and spermatozoa. The nephridia may be especially modified for carrying off these sex cells, in which case they are known as gonoducts. Even among the vertebrates the oviducts and spermiducts (*vasa deferentia*) are derived from the nephric

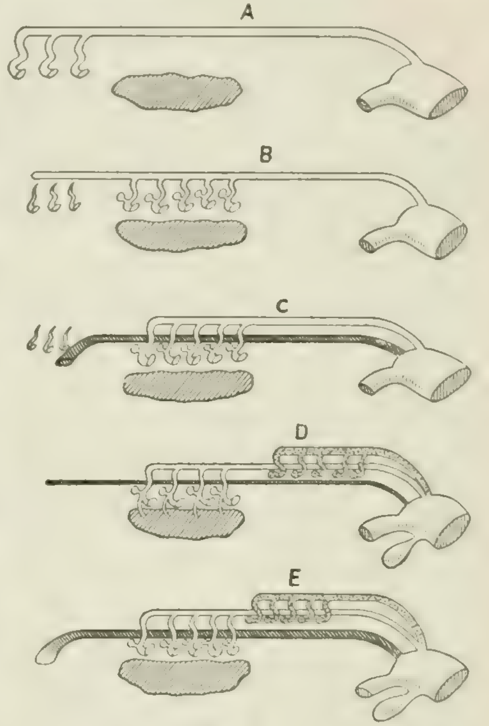

Fig. 19

Fig. 19.— Diagrams illustrating the development of the urino-genital organs of a vertebrate (after Parker and Haswell).—*A*, pronephros and segmental duct; *B*, atrophy of pronephros, development of mesonephros; *C*, appearance of Müllerian duct; *D*, development of metanephros, male type; *E*, the same, female type. system. The former in most vertebrates arises in the embryo as part of the segmental duct and opens into the body cavity at its anterior end through a pronephric tubule; the latter is the remainder of the segmental duct, and in animals above the amphibians, which have a metanephros and ureter, acts exclusively as a spermiduct.

8. *Reproductive System.* — Reproduction among animals is both sexual and asexual; the former occurs among all animals, the latter is limited to the lower forms and to the constituent cells of higher ones. Sexual reproduction or amphigony consists in the union of two cells, the sex cells or gametes, to form a single cell of double origin, the oosperm or zygote, from which a new individual similar to the parental form develops. If the gametes are approximately equal in form and size their union is spoken of as conjugation, if they are very unlike in these respects they are called ova and spermatozoa, and their union is known as fertilization. Both conjugation and fertilization occur among the *Protozoa*, whereas all *Metazoa* reproduce by means of differentiated sex cells, namely, ova

and spermatozoa. In a few animals ova have the power of developing without previous fertilization, the process being known as parthenogenesis. If such development without fertilization occurs in larval forms which have not completed their development it is known as pædogenesis. In most animals the sexes are separate,—that is, ova and spermatozoa are produced by different individuals, males and females, and the species is diœcious; in some cases, however, both kinds of sex cells are produced by the same individual, which is then said to be hermaphrodite, and the species to be monœcious.

The essential reproductive organs are the gonads, or the glands which produce ova and spermatozoa, namely, the ovaries and the testes. In sponges the reproductive cells are scattered through the mesoderm so that in these animals ovaries and testes cannot be said to exist. In the lowest cnidarians (*Hydrozoa*) the sex cells are at first widely scattered in the ectodermal epithelium, but they actively migrate to certain portions of the hydroid stem where reproductive buds are being formed, and, aggregating here, form gonads. In all higher animals definite gonads are present. No genital ducts are present in the cœlenterates, and none are needed, since the sex cells can escape directly into the water. In animals above the cœlenterates the sex cells are mesodermal in origin, and in most cases form a part of the epithelium lining the cœlom. In animals without a true cœlom the sex cells arise within tubes or glands the cavities of which may perhaps represent the cœlom. In flatworms the gonads occur in considerable numbers in a single individual. In roundworms they are limited to one or two tubes, in rotifers, mollusks, molluscoids, and echinoderms they are confined to one or at most a few sex glands, while in segmented animals they are found in primitive forms in every body somite, though with advancing organization they become limited to a few segments or even to one. In most animals above the cœlenterates some form of duct exists for carrying the sex cells to the exterior; among the flatworms, roundworms, and rotifers these ducts are never the excretory tubules, though they may possibly represent the cœlom of higher animals. In these higher forms they are frequently metanephridia, or modified excretory ducts.

In many animals the ova and spermatozoa escape directly into the water, and there the eggs are fertilized and undergo development; it is probable that in these animals the escape of ova stimulates the males to eject spermatozoa so that both kinds of sex cells are shed at about the same time. In such cases enormous numbers of sex cells are produced and very many are wasted. A slight advance over this condition is found in those animals (frogs, bony fishes, etc.) in which the openings of the male and female ducts are placed close together at the time of shedding the sex cells; this is known as external copulation. In other cases the spermatozoa only escape from the body, and by means of currents of water they are carried into the body of the female, where they fertilize the ova *in situ*, as in sponges, or in certain receptacles into which the eggs are collected, as in fresh-water mussels. In other animals copulatory organs exist which serve to introduce spermatozoa into the sex ducts of the female, thus increasing the chances for the fertilization of the ova; this is internal copulation. In many cases copulation occurs but once, and the spermatozoa are stored in a seminal receptacle which opens into or near the oviduct. Internal copulation is a necessity in all land animals and in parasites, and it also occurs in many phyla of invertebrates (flatworms, roundworms, rotifers, gasteropods, cephalopods, annelids, arthropods).

In certain animals the sexes differ not only with respect to the sexual apparatus but also in many other regards; when such differences are very marked they constitute what is known as sexual dimorphism. In such cases the male is frequently very degenerate in form, being sometimes not more than a hundredth part the size of the female and entirely lacking alimentary canal, sense organs, and nervous system (rudimentary males of rotifers, barnacles, etc.).

Asexual reproduction, or monogony, consists in the formation of new individuals by division of an old one. In one-celled organisms and in the constituent cells of higher animals this takes the form of cell division. In the lower *Metazoa* asexual reproduction is not limited to cell division, but the entire body or portions of it may undergo constriction and subsequent division, thus giving rise to new individuals. This division may be into equal parts, in which case it is called fission; or into unequal parts, when it is known as budding or gemmation. In animals which reproduce both sexually and asexually there is a more or less regular alternation of one method with the other; this is known as alternation of generations or metagenesis. The alternation of amphigony with parthenogenesis is called heterogony.

9. *Nervous System and Sense Organs.*— Sensation and co-ordination are manifestations of protoplasmic irritability, or that capacity of receiving and responding to stimuli characteristic of every cell. Animals, even the simplest, are sensitive to a variety of stimuli, among which may be mentioned mechanical, chemical, thermal, and electrical, as well as light, gravity, etc. These stimuli, acting on the organism, start changes in the protoplasm (impulses) which are transmitted to portions of the body distant from the point first stimulated and call forth the co-ordinated activities of many different parts. In higher animals there are special sense organs for receiving certain of these stimuli and specialized protoplasmic fibres (nerve fibres) for transmitting impulses, while nerve centres for co-ordinating activities appear very far down in the animal scale. In the lowest animals, however, there are neither nervous system nor sense organs, and yet through the irritability of the general protoplasm these functions are performed.

A protozoan reacts to all stimuli in the same way, and it is probable that however different the stimuli may be they produce essentially the same changes in the protoplasm. The sensations of *Protozoa*, if they can be said to have sensations, must be of the most general and indefinite sort, just as their responses to stimuli show the most monotonous sameness. The same thing is probably true of sponges, where none of the cells are differentiated for receiving and transmitting stimuli. In all other phyla, however, certain cells of the body are set apart for these particular functions, and

the greater the differentiation in these respects the more definite and varied are the sensations, the more swiftly impulses are transmitted to the motor system, and the more complicated are the responses.

Nervous System.— The elements out of which the nervous system is built are nerve cells and fibres, the latter being merely outgrowths of the former. In practically all *Metazoa* these cells are derived from ectoderm, and in a good many animals the sense organs and entire nervous system remain throughout life a part of the superficial epithelium which covers the body (*Cœlenterata, Chætognatha,* certain *Annelida, Molluscoidea,* many *Echinodermata, Balanoglossus*); such a nervous system is said to be epithelial. In all other *Metazoa* the nervous system, though formed from epithelium, separates from it in the process of development, so that brain, ganglia, and nerve trunks come to lie some distance from the surface of the body; this is known as an epitheliogenous nervous system. In addition to the two classes just mentioned, which are based on the relations of the nerve cells to the body layers, four types of nervous system are found among *Metazoa* which are based upon the relations of the nerve cells to one another; these are (1) the diffuse type, (2) the linear type, (3) the ganglionic type, and (4) the tubular type.

(1) A diffuse nervous system consisting of nerve cells and fibres scattered throughout the superficial epithelium is the simplest type known and is found among such animals as sea-anemones (*Actinozoa*); the nerve cells are here connected together by means of the fibres into a ganglionic plexus. (2) The next step in increasing complexity is represented by a linear nervous system such as is found in the jelly-fishes; here many nerve cells and fibres are aggregated into a double nerve ring around the

margin of the umbrella, thus forming a centralized nervous system; other nerve cells remaining, scattered throughout the epithelium, serve to connect the ganglia with the muscles. (3) The ganglionic type. In ctenophores, a sense organ from which nerves radiate, is found at the apical pole, and in a great many of the higher animals the earliest formed and most widely represented portion of the nervous sys-

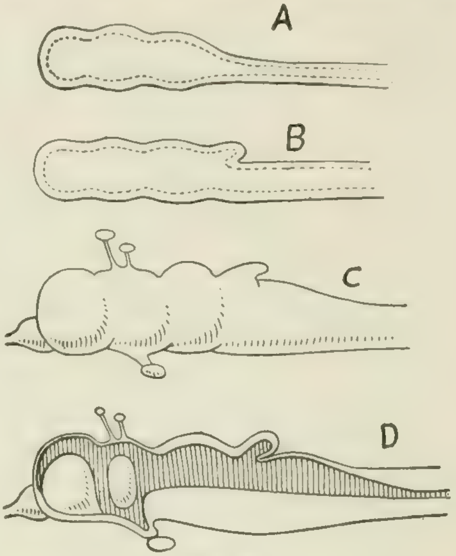

FIG. 24

FIG. 24.— Diagrams of the vertebrate brain (after Parker and Haswell).— *A*, first stage, with three brain vesicles; *B*, second stage, four brain vesicles; *C*, *D*, side view and sagittal section of fully formed brain without cerebral hemispheres.

tem is a sense organ and ganglion which appear at the apical pole of the gastrula, and becomes in the adult the cerebral ganglion or brain, lying on the dorsal side of the œsophagus. Nerve trunks are always given off from this ganglion, and very generally two of them run down on each side of the œsophagus to its ventral side, thus forming a circumœsophageal nerve ring. In different phyla longitudinal nerve trunks may be given off from different parts of this ring; among annelids, arthropods, mollusks, and molluscoids from the ventral side, and in annelids and arthropods this forms the "ventral chain," which consists typically of a pair of ganglia in each somite connected with those in front and behind by nerve cords. The first one in the chain is the subœsophageal ganglion, connected with the cerebral ganglion by the circumœsophageal commissures. In the mollusks the nervous system consists of a pair of supra- and sub-œsophageal ganglia (cerebral and pedal) which with their connectives form an œsophageal ring. To these is usually added a pair of pleural and of parietal ganglia forming a loop which extend back into the body, while ventral trunks (pedal cords) may be present in the foot. (4) The tubular type of nervous system is found only among the chordates; here the nervous system develops from an epithelial plate (neural plate) on the dorsal surface of the embryo, which becomes invaginated in such a way as to form a longitudinal groove, the neural groove. This then separates from the epithelium as a tube, which in all vertebrates is enlarged at its anterior end to form the brain. This neural tube,

while apparently a continuous structure, is really composed of segments, the neuromeres, one neuromere being found in each body somite; the neuromeres are thus comparable to the ganglia of the ventral chain of arthropods and annelids. This segmentation of the central

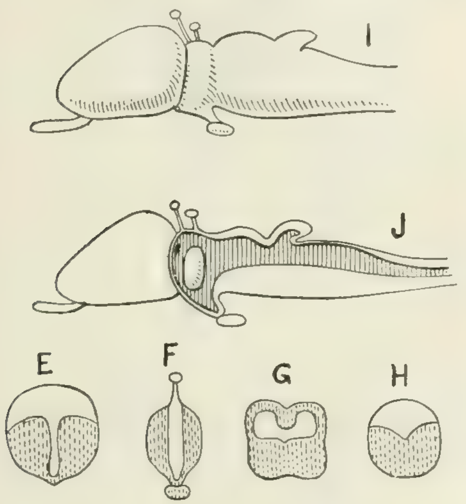

Fig. 25

Fig. 25.— Diagrams of vertebrate brain (after Parker and Haswell).— *E — H*, transverse sections of brain at different levels; *E*, of the cerebrum; *F*, of the 'tween brain; *G*, of the mid brain; *H*, of the hind brain; *I*, *J*, side view and sagittal section of a brain with cerebral hemispheres.

nervous system of vertebrates is indicated even in the adult by the segmental arrangement of the spinal and cranial nerves. In the embryonic development of all vertebrates the brain consists of three enlargements or vesicles, the fore brain, mid brain, and hind brain; the first gives rise to the cerebrum and 'tween brain of the adult, the second remains as the mid brain, while the third gives rise to the cerebellum and medulla. The portion of the neural tube posterior to the brain becomes the spinal cord of the adult. With the differentiation of nerve cells and fibres in the walls of the neural tube these walls increase greatly in thickness, while the originally large cavity of the tube becomes restricted in size, forming in the adult the ventricles of the brain and the central canal of the cord.

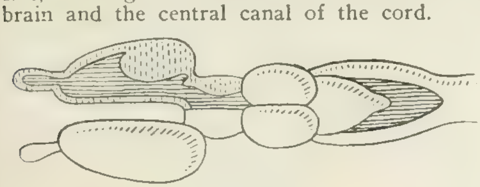

Fig. 26

Fig. 26.— Dorsal view of vertebrate brain with the cavities of the right side exposed (after Parker and Haswell).

Sense Organs.— The simplest sense organs are the scattered sensory cells found in the superficial epithelium of many animals; these may be solitary or aggregated into buds. They are elongated epithelial cells with a hair-like process at the free border and a fibre at the deeper end connecting with the branches of a ganglion cell. They are organs of general sensation,— that is, they are capable of receiving various kinds of stimuli, such as mechanical, thermal, electrical, and chemical, and are therefore largely undifferentiated, though probably chiefly subserving the sense of touch. These integumentary sense organs are found in almost every group of animals. Among the vertebrates they are present in primitive form over the general body surface; in the fishes and amphibia they are aggregated into buds, forming the lateral line organs, while among those vertebrates which do not dwell in water deeper-lying organs, of modified type, are found (tactile cells, corpuscles, and bulbs). In addition to these organs of general sensation, higher *Metazoa* generally possess specific sense organs, namely, those differentiated for the reception of particular kinds of stimuli. These are organs of (1) smell and taste, (2) equilibrium and hearing, (3) vision.

(1) Organs of smell and taste are present in all vertebrates and in many invertebrates. Their structure is extremely simple, being but slightly modified from the type of the primitive organs described above. In fact the olfactory sense cells of vertebrates are merely scattered sensory cells, while the organs of taste (taste buds) are simple aggregations of such cells. Throughout the *Metazoa* the organs of taste and smell are generally located in ciliated pits or depressions of the integument either on the head or at least near the mouth or respiratory organs. In these positions they serve in the one case to test food and in the other the quality of the medium used in respiration. Among fishes the olfactory organs are located in pits on the front of the head; in all air-breathing vertebrates these open posteriorly into the mouth cavity or pharynx, and thus form the anterior part of the respiratory tract. The organs of taste are of course in or near the mouth. Among the mollusks a sense organ which is probably olfactory in function, the osphradium, is located near the gills. Among the arthropods we find notable modifications of these organs owing to the fact that the entire body surface is there covered with an impermeable chitinous coat. These sense organs are here peculiar hollow tubes, the olfactory tubes or cones, which are borne on the anterior portion of the body, usually on the antennæ and mouth parts; these hairs are filled with fibrillar protoplasm which connects with sense cells at the base of the hair.

(2) Organs of hearing and equilibration are very widely represented throughout the animal kingdom. It is advisable to consider these two organ systems together, since the two functions which they subserve are united in the same general organ in the vertebrates, while in lower forms it is by no means easy to distinguish between the two. It has long been customary to speak of all vesicular sense organs containing free solid bodies as auditory in function, but it is much more likely that in the lower *Metazoa* they serve to acquaint the animal with its bodily positions,— that is, that they are organs of equilibration. In many respects the simplest type of organ of this class is found among certain jellyfishes. It here consists of a short tentacle situated in a depression of the ectoderm and bearing a solid body or otolith near its free end; by the movements of the tentacle the

hairs or protoplasmic processes of surrounding sensory cells are stimulated. In other *Medusæ* the sensory cells may entirely enclose the ten-

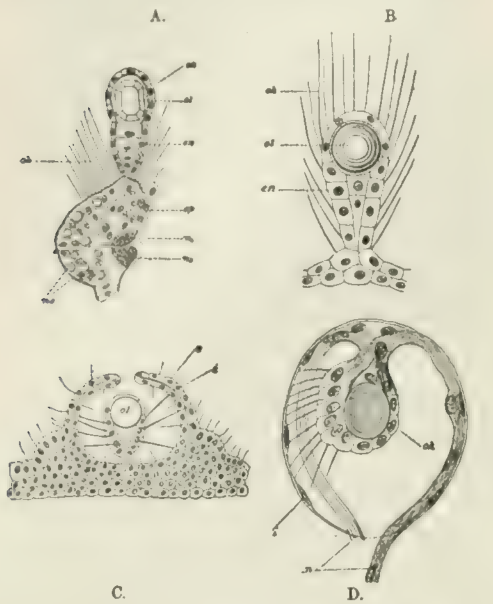

FIG. 27

FIG. 27.—Auditory or equilibrative organs of jelly-fishes (from Hatschek).—*A*, of *Cunarcha*. *B*, of *Pectis*. *C*, of *Rhopalonema*. *D*, of *Cumarina*. *Ok*, auditory tentacle; *Ol*, Otolith; *Oh*, auditory hairs; *n*, nerve.

tacle, thus forming an auditory vesicle or otocyst. The auditory organs of most vertebrates, as well as of most invertebrates, can be traced back to this simple type. The sensory cells forming the walls of the otocyst are similar to tactile cells,—that is, they bear processes projecting into the cavity of the otocyst, while the bases of these cells are connected with ganglion cells. By the movements of the otolith, usually a calcareous concretion, these cells are stimulated and the impulses thus generated conveyed away by the nerve fibre. Otocysts of this type are possessed by mollusks, certain

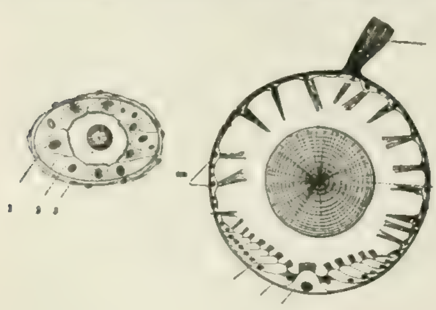

FIG. 28

FIG. 28.—Auditory or equilibrative organs of mollusks (from Hatschek).

annelids, turbellarians, and brachiopods. In the case of arthropods organs of a different type are generally found, owing to the fact that the body is here covered by chitin and that the fine protoplasmic processes or cilia are absent. Among the crustaceans the auditory organ usually consists of a cavity in the basal joint of the first antenna, which is open to the exterior and which contains water and grains of sand; the wall of the cavity bears chitinous processes or auditory hairs which have a nervous connection at their base; these hairs are stimulated by the movements of the water and sand within the auditory sac. Many insects have a true tone-perceiving organ, the chordotonal organ; in principle this consists of a few elongated cells, the chord, which are attached directly to the integument at one end and by a ligament to an opposite point of the integument; when this apparatus is thrown into vibration impulses are conveyed to the nerve cells attached to some portion of the chord. In other insects (*Orthoptera*) a tympanal organ may be present, consisting of a vibrating membrane overlying a tracheal chamber; sense cells are present between the membrane and chamber, and when the membrane is set into vibration by sound waves the sense cells are stimulated. Among aquatic vertebrates a system of integumentary

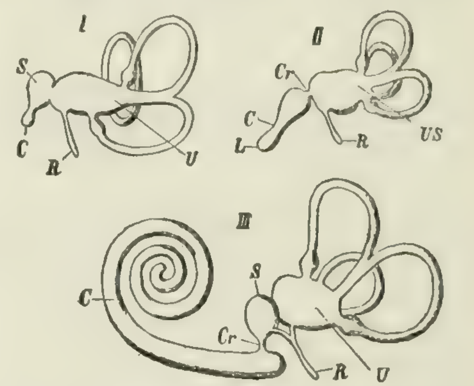

FIG. 29

FIG. 29.—Internal ear of different vertebrates. I, Fishes. II, Birds. III, Mammals. (From Claus.)—*U*, utriculus with semicircular canals; *S*, sacculus; *US*, utriculus and sacculus; *C*, cochlear duct; *L*, lagena; *Cr*, *canalis reuniens*; *R*, *recessus vestibuli*.

sense buds is found along the lateral borders of the body and over the head, which is known as the lateral line system. The function of these organs is not surely known, but it is probable that they are organs of touch and also of equilibration. In all vertebrates it is probable that the auditory organs, as well as the organs of smell and taste, have been derived from integumentary sense organs homologous with those of the lateral line. In the process of development the ear appears as a pit-like invagination of the skin which is then infolded to form a vesicle; this vesicle then becoming partially divided into two chambers, the utricle and the saccule. In most vertebrates the former bears three pairs of semicircular canals which are organs of equilibration, while the latter gives rise to a recess, the lagena, which becomes the cochlear duct in mammals and is a true auditory organ. Calcareous concretions or

otoliths are present in this much-folded and complicated otocyst. This sensory portion of the auditory organ is known as the inner ear;

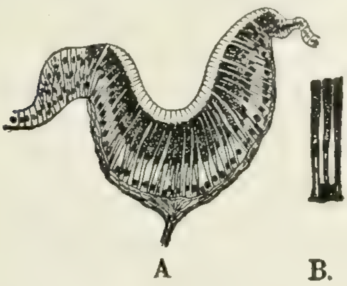

FIG. 30

FIG. 30.—*A*, section through the open eye-pit of a limpet (*Patella*); *B*, the two kinds of retinal cells, pigmented and sensory (from Hatschek).

to this is added in all animals above the frogs and toads a middle ear or tympanum which transmits the sound waves from the surface to the inner ear. Finally, in the mammals there are folds of the integument around the tympanic membrane which serve to collect sound waves and which constitute the external ear.

(3) *Visual Organs.*— Animals without any trace of eyes are sensitive to light (certain *Protozoa, Turbellaria, Larvæ*), and it must therefore be assumed that protoplasm may be directly stimulated by light without the intervention of any special organ. In its simplest form an eye consists of one or a few transparent cells partially surrounded by pigment in the form of a cup, so that the light can enter only from one side; the pigment not only absorbs light rays, but it optically isolates the cells within from those without this cup (some *Medusæ, Turbellaria, Annelidæ*). The function of such an eye is probably to determine the direction of light, since it could give no image of luminous objects. A slight advance over this simplest type of eye is found in the cup-shaped eyes of certain mollusks; here certain superficial epithelial cells are infolded to form a cup; in some cases deeply pigmented, while other intermediate cells remain clear and unpigmented. The latter

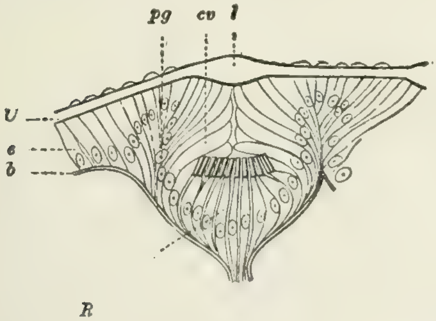

FIG. 31

FIG. 31.— Section through the eye of a water-beetle (*Hydrophilus*) (from Hatschek); *l*, chitinous lens; *cv*, transparent cells; *pg*, pigment cells; *R*, retina.

are the sensory cells and are connected at their bases with nerve fibres. If this cup-shaped eye becomes infolded still further and its opening grows smaller and finally closes altogether, it forms a vesicular eye such as is present in certain mollusks and annelids. The wall of this vesicle, which is turned toward the epithelium, is transparent and may become thickened to form a lens; the opposite wall of the vesicle is pigmented and is known as the retina. In such an eye the free ends of the retinal cells are turned toward the cavity of the vesicle, while the opposite ends, which are directed away from the vesicle, are prolonged into fibres; such an eye has a direct retina. This type of eye reaches its highest development among the cephalopods, where it bears a striking superficial resemblance to the vertebrate eye. A rudimentary eye of this type is present in all vertebrates as the pineal organ or gland. This is an unpaired structure on the dorsal side of the

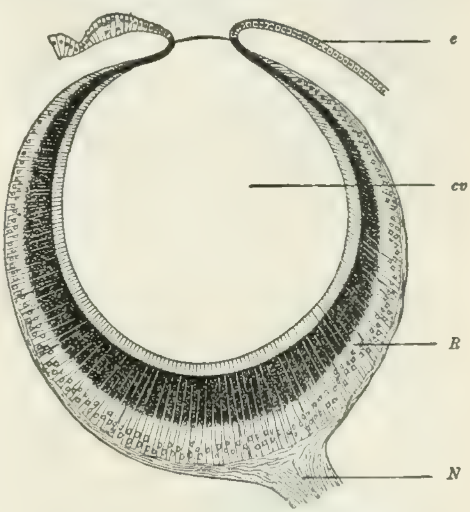

FIG. 32

FIG. 32.— Section through the cup-shaped eye of a gasteropod (*Haliotis*) (from Hatschek).— *e*, epithelium covering body; *cv*, vitreous body; *R*, retina; *N*, nerve.

'tween brain and in certain reptiles is plainly a vesicular eye with direct retina. The paired eyes of vertebrates are also vesicular, but in them the retina is inverse,— that is, the free ends of the retinal cells are directed away from the cavity of the vesicle, while the ends which bear the fibres are directed toward it. The explanation of this remarkable condition is found in the study of the development of these eyes. They arise as lateral evaginations of the walls of the embryonic fore brain, are then constricted from the brain, and become vesicles connected with the fore brain by only a stalk. At this stage the vertebrate eye is like the invertebrate one save only that it has arisen from the neural instead of the superficial epithelium. All the cells which form the vesicle have their free ends directed toward its cavity, while their basal ends are directed away from it. The outer wall of this optic vesicle is then infolded until it comes into contact with the inner wall, thus forming a cup open toward the skin. The ectoderm over

FIG. 33.— Longitudinal section through the pineal eye of a lizard (*Sphenodon*) (after Baldwin Spencer), The eye is located in the middle of the dorsal side of the head and is covered by translucent scales. The outer wall of the eye vesicle is thickened to form a lens, while the inner pigmented wall is the retina from which the nerve proceeds.

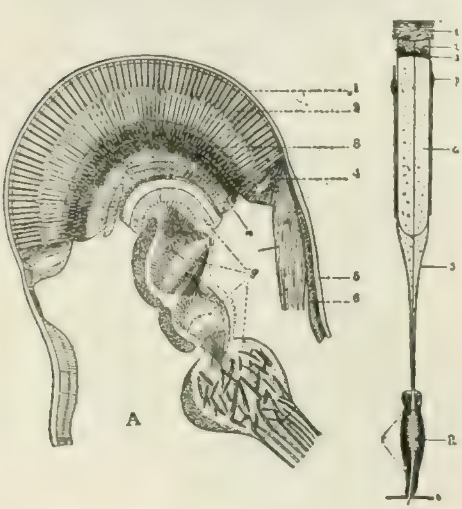

FIG. 34

FIG. 34.— A, section through the compound eye of a crayfish (from Hatschek).— 1, cornea; 2, crystalline cones; 3, retinulæ; 4, pigment cells; 5, cuticle; 6, epithelium; *n*, optic nerve, *g*, ganglia. B. A single element (ommatidium) from the compound eye of a crayfish.— 1, corneal lens; 2, corneal cells; 3, crystalline cone cells; 4, 5, outer and inner parts of the crystalline cone; *p*, pigment cells; *r*, retinula; *R*, rhabdome; *b*, basement membrane.

the opening of the optic cup is then infolded to form the lens, which completely separates from the surface and lies in the mouth of the cup. The infolded wall of the cup alone forms the retina, and therefore the free ends of the retinal cells are directed away from the lens and the cavity of the cup. The lens and optic cup are then surrounded by fibrous and vascular coats, the sclerotic and choroid; a chamber is formed in front of the lens which is filled with water or aqueous humor, while one behind the lens and in front of the retina is filled with vitreous humor.

The compound eye is another type found chiefly among arthropods. It consists of a large number of closely-packed single eyes or ommatidia, each of which is surrounded by pigment and is optically isolated from the others. Each ommatidium consists of (1) a hexagonal cornea at the surface, (2) a crystalline cone below this, and (3) the retinula or group of retinal cells which are connected with nerve fibres. The cornea and crystalline cone are refractive and serve in the capacity of a lens, while the retinula alone is the sensory element.

EDWIN GRANT CONKLIN,
University of Pennsylvania.

Anatomy of Melancholy, The, a famous work by Robert Burton (1577–1640). It was first issued in 1621 under the name 'Democritus Junior,' and was revised five times by the author before his death. It is divided into three systematic sections devoted respectively to the causes and symptoms of melancholy, its cure, and of amorous and religious melancholy. It is in effect an *omnium gatherum* of all sorts of out-of-the-way lore, from diet to demonology, and its literary felicity and humor have aided in keeping it alive as genuine literature.

Anatomy of Plants. The cell, the elementary organ of plants and animals, was first observed by the English micrographer Robert Hooke (1667), who suggested the name "cell" because of its resemblance to the cell of a honeycomb. A few years later another English author, Nehemiah Grew, extended this observation and published the first work on plant-anatomy (1672), in which he described the minor structure of leaves, stems, and roots, and introduced several anatomical terms still in use. Grew was soon followed by an Italian, Marcello Malpighi, the author of the illustrious work, 'Anatome Plantarum' (1675), and these three men are thus the founders of the science of plant anatomy. Many years later Robert Brown (1833) detected the nucleus in the cell, and the German botanist Schleiden (1838) pointed out the general occurrence of this new body within the cells of plants and its importance to the cell-division. These discoveries soon led to the apprehension of the cell as being the elementary organ of plants, and when the occurrence of nucleus had been proved also in the cells of animals the German naturalist Schwann (1839) advanced the important doctrine that bodies of animals and plants consist of cells and the products of these.

While the nucleus had thus been detected and described to some extent, there still remained a closer examination to be made of the other parts of the cell-content, which some of the earlier investigators had already observed and described as a soft, gritty matter, capable

of motion in the cell. This cell-content was studied by Mohl (1846), who gave it the name protoplasm. The constituents of the cell were thus properly defined as the cell-wall, the protoplasm, and the nucleus. Of these the protoplasm and the nucleus are the most essential parts, since the wall is not always developed, but is totally absent in numerous animal-cells and also in those of several plants among the lower *Algæ* and *Fungi*, at certain stages, for example. A completely developed plant-cell may for the most part be defined as a microscopical, closed vesicle consisting of a wall, and the contents, nucleus, protoplasm, and cell-sap. The shape of the cell presents a vast number of forms, generally referred to only two types: the parenchymatic and the prosenchymatic. Of these the parenchymatic is either isodiametric or elongated, but with blunt ends and usually thin-walled, while the prosenchymatic is mostly elongated with pointed or sharp endings, and is more or less thick-walled. A third type of cell may be mentioned, the "hypha" of certain *Algæ* and *Fungi*, which is very thin, thread-like, and composed of a single cell or many. There are plants consisting of one cell only, but most plants are composed of an enormous number, which together constitute the so-called "cellular tissues," parenchyma and prosenchyma, in respect to the shape of the cells of which they are composed. The function performed by these tissues is very different, and the classification as parenchyma and prosenchyma is thus not sufficient, since this only applies to the external shape of the cells. In accordance with both structure and function the following tissues are observable in the higher plants: Epidermis, the mechanical tissue, the conductive tissue, and the fundamental tissue; the first and the last of these tissues being parenchymatic, the others prosenchymatic.

The minor structure of these various tissues may be described as follows:

Epidermis.— This is the outermost cell-covering of a plant-organ, such as the leaf, stem, and root, and consists of at least one layer of cells. The outer cell-wall is often considerably thickened and invariably covered by a thin membrane, the so-called cuticle (*c* in Fig. 1) which

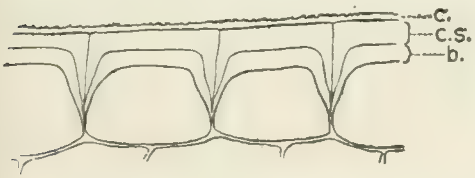

Fig. 1.— Epidermal cells of the leaf of aloe: *c*, the cuticle; *c.s.*, cuticular layers; *b*, cellulose.

is highly impermeable to water, and especially well-developed in land-plants; in submerged water-plants the cuticle is, on the other hand, much reduced. The epidermal system of plants has a threefold significance: it protects the more delicate parts of the organs against mechanical injuries, pressure, etc.; it forms a protection against evaporation by being impermeable to water and water-vapor, and forms also a water-supplying system. These three functions are expressed by various development of the cells, which may be illustrated by a section of a leaf of aloe (Fig. 1) in which all three epidermal peculiarities are quite well developed. The thick cuticle and cuticular layers

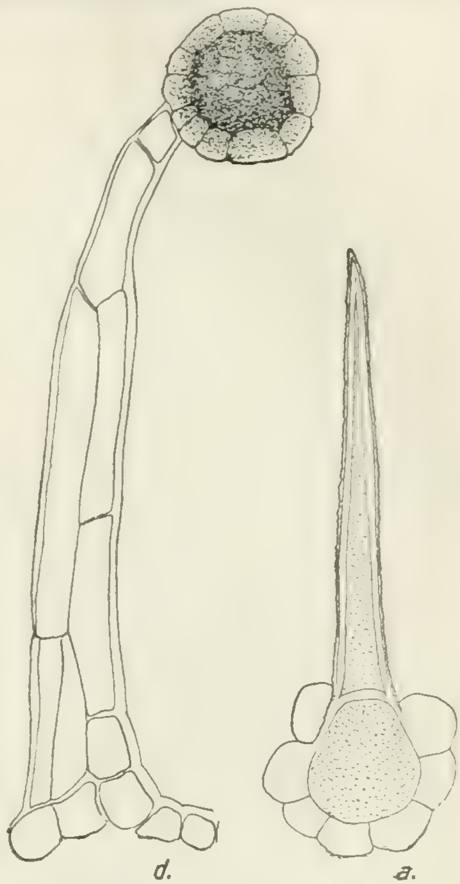

Fig. 2.— *a*, simple hair of *Mertensia*: *d*, glandular hair of *Saxifraga*.

form an excellent protection against loss of moisture, while the thickening of the outer cell-wall and portion of the radial walls furnishes the mechanical support. Characteristic of epidermis, furthermore, is its covering of hairs, which present a number of forms, and of which the majority are developed from the epidermis itself. Some of them consist only of a single

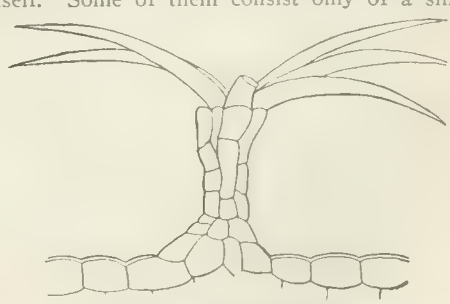

Fig. 3.— Branched hair of *Croton*.

cell, but usually they are composed of several. The hairs may be simple (Fig. 2. *a*) or branched (Fig. 3), and attain various forms from sharply-

pointed to globose, scale-like (Fig. 4) or star-shaped. The ordinary hairs contain only air, and when occurring as a dense covering of the

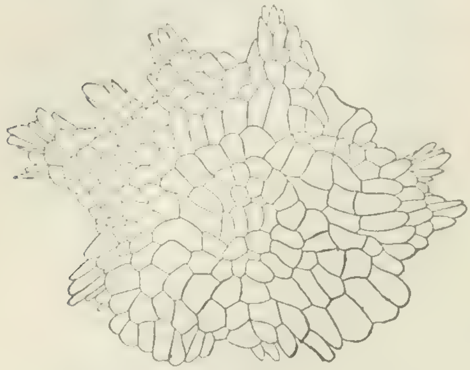

FIG. 4.— Scale-like hair of *Tillandsia*.

plant-organ aid materially in the protection against loss of moisture, thus entering directly into the function of epidermis. Other hairs contain and secrete ethereal oils, the so-called glandular hairs (Fig. 2 *d*), which may serve for attracting insects to carry the pollen, or if the secretion is of a sticky consistence, the function may be to keep off injurious, crawling insects, less adapted for aiding in cross-fecundation. Several hairs contain poisonous matters and cause great pain when touched, as for instance the hairs of the common nettle, but the physiological significance of such and other hair structures is not satisfactorily explained.

A very simple structure is possessed by the root-hairs, which consist of only a single epider-

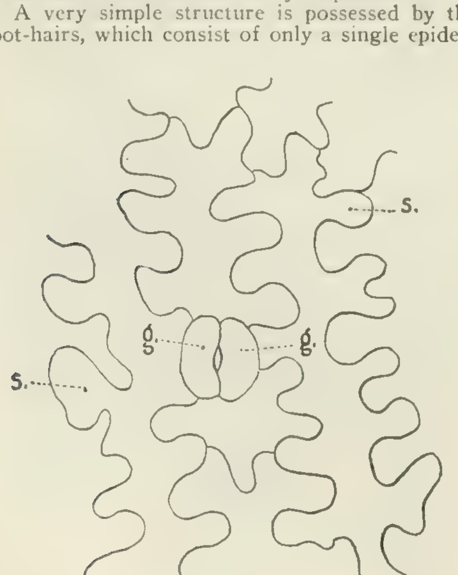

FIG. 5.— Epidermis, with stomata, of *Medeola: g*, the two guard-cells; *s*, the subsidiary cells.

mis-cell, and of which the function is to absorb and conduct food substances in solution. A purely mechanical function is exhibited by the climbing-hairs,— that is, hairs in the shape of hooks by which the weak stems of certain plants — for instance, hop, cleavers, etc.— are able to climb by attaching themselves to other plants.

Finally to be mentioned are the stomata. If the epidermis be able to regulate the evaporation, it is readily understood that this tissue must be compact and without intercellular spaces unless these be capable of closing and opening themselves under certain conditions. Such intercellular spaces occur in the epidermis

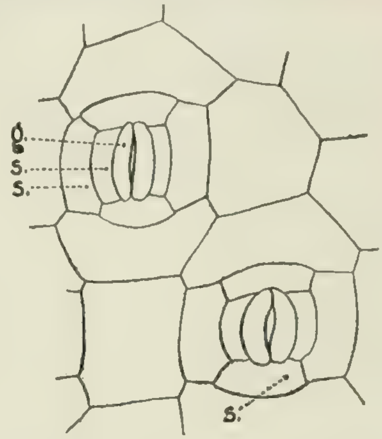

FIG. 6.— Epidermis, with stomata, of *Commelina: g*, guard-cell; *s*, subsidiary cells.

and were by De Candolle named "stomata." Each stoma consists of two crescent-shaped cells (*g* in Fig. 5), the guard-cells, which turn their concave faces against each other, thus forming an intercellular space leading into a wide cavity, the so-called air-chamber (*ac* in Fig. 7). Adjoining the guard-cells are usu-

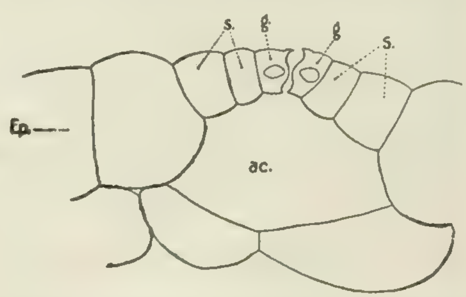

FIG. 7.— Cross-section of a stoma from the leaf of *Commelina: ac*, the air-chamber; *g*, guard-cells; *s*, subsidiary cells.

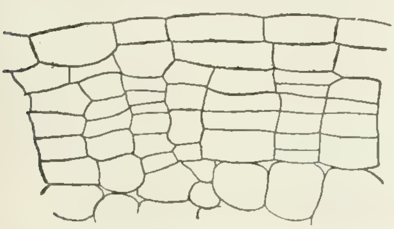
ally two or more epidermis-cells of a shape somewhat different from the others, and these have been called the subsidiary cells (*s* in Fig. 5); their number and manner of arrangement is often very variable in several orders of the phanerogams. The guard-cells are, as a rule, the only cells of epidermis which contain chlorophyll and starch; they have the power of closing or opening the orifice of the intercellular space, a phenomenon that has been studied and explained by Schwendener. When moist these

cells become swollen, and, as they lengthen, curve outward in the middle so as to leave a free opening. An opposite movement takes place when they become dry: they are then shortened and straightened with their inner faces applied to each other, closing the orifice. Stomata occur as a rule on all green plant-organs, stems, and leaves, but lack in those that are constantly under water, and they are totally absent in the thallophytes. The location of the stomata varies somewhat, but they are more numerous on the lower face of the leaves than on the upper. Their position offers a number of variations and is sometimes dependent upon the nature of the surroundings, especially of the climate, the dryness of the air, etc. The guard-cells may be free, reaching above the surrounding epidermis (Fig. 7), or they may be sunk below this. A very peculiar arrangement is noticeable in *Nerium,* where the stomata are located, several together, in depressions of the leaf-surface. A modification of stomata are the so-called water-pores, exhibiting a like structure, but somewhat larger than these and unable to open or close themselves. They are mostly located on the margins of leaves near the ends of the nerves.

The Cork.— While the epidermis is seldom of any long duration in plant-organs which



C.

Fig. 8.— Cross-section of the stem of *Trifolium,* showing the cork (*c*).

persist for more than one season, another covering becomes necessary and is represented by the so-called cork. This tissue may be developed by the epidermis itself, but in most instances it originates in the parenchymatic layers underneath the epidermis, or sometimes much deeper, in the innermost portion of the cortex, for instance. The cork is able to continue its growth, following the increase in thickness of the stem, and consists of several strata of quadratic or rectangular cells, arranged in compact rows, vertical on the surface of the plant-organ (Fig. 8).

The Mechanical Tissue.— The best known elements of this tissue are the so-called "stereome-cells," which are thick-walled, very long prosenchymatic cells, of which the walls have narrow pores and consist of cellulose. The stereome-cells are mostly arranged in strands and located in such portions of leaves or stems as are the most exposed to injury. The cells are very flexible, and the arrangement of the layers is remarkably well fitted for rendering the plant-organ the greatest possible support by means of the smallest quantity of material, as demonstrated by Schwendener. Besides this function the mechanical tissue is also observed to form protective layers around the mestome-bundles, especially near the leptome-elements.

Another thick-walled but parenchymatic cell-form is the so-called sclerotic, occurring in the cocoa-nut, walnut, etc.

The collenchymatic cells may be mentioned here: they are elongated, prismatic cells of which the walls are thickened only in the corners and consist mainly of cellulose. Collenchymatic tissue is frequent in the periphery of stems of herbaceous plants, and in leaves, near the larger nerves of these.

The Conductive Tissue.— This tissue is represented by the so-called "mestome-bundles," or "vascular bundles" of earlier authors, which traverse the plant-organs mostly in a longitudinal direction; they constitute a part of the nerves in leaves and of the wood in trees. Their composition is often very complicated, especially in stems and roots, where they are often associated with some of the other tissues, from which they are not always readily distinguished. At present "mestome," as proposed by Schwendener, comprises only two elements, "leptome" and "hadrome," of which the former conducts albuminous matters and contains the sieve-tubes and the medullary ray-parenchyma. The hadrome contains the vessels and the woody parenchyma and conducts the water. These terms, leptome and hadrome, are not identical with the "phloëm" and "xylem" formerly suggested by Nägeli, since this author included the mechanical tissue, the stereome, which is often developed in almost immediate connection with the true conductive tissue.

Mestome-bundles, containing leptome and hadrome, are observable in all the higher plants: vascular cryptogams and phanerogams, but are not developed in any of the thallophytes (*Fungi* and *Algæ*) or in the mosses. In regard to the various cell-forms represented in the conductive tissue or mestome, the so-called vessels play an important role by their characteristic structure. Vessels are tubes which have been developed from cell-rows whose transverse walls have either entirely or partially disappeared, leaving ridges or rings, and of which the longitudinal walls are strengthened by various thickenings. The so-called "tracheids" are somewhat modified forms of vessels, but hardly distinguishable from them except by their narrower width. Both vessels and tracheids occur under the same types as "spiral," "reticular," "scalariform" and "porous," in accordance with the manner of thickening observable in their walls; of these the porous tracheids are particularly numerous. The wood of conifers consists exclusively of such porous tracheids, which are especially characteristic by the pores being bordered.

The woody parenchyma and medullary rays resemble in structure those parenchymatic cells having numerous rounded, simple pores, but differ in their position and arrangement: the former usually extending longitudinally in the shape of bands, while the medullary rays represent radial bands or plates. Some distinction is also noticeable in the shape of these cells: that of the wood-parenchyma being elongated in the direction of the axis of growth, while the cell of the medullary ray is chiefly elongated in a radial direction.

The leptome contains, as stated above, the sieve-tubes with the cambiform. This tissue differs widely from the hadrome in the great

softness and much narrower lumen of its individual cells. The sieve-tubes are usually elongated cells of which the transverse walls exhibit a very distinct perforation, whence the term sieve-plate is generally given to this particular cell-wall. The openings in the sieve-plates permit the circulation of undissolved albuminous matters. The sieve-tubes and plates are often difficult to observe on account of their delicate structure and minute size; they are, however, well distinguishable in the stems of the grape-vine and of the *Cucurbitaceæ*.

There is still a small conducting system, which may be mentioned here, although belonging either to the leptome or the hadrome. It is the lactiferous tissue, containing the so-called milk-tubes, often located in the neighborhood of the leptome. The cell-wall consists of cellulose: it is as a rule very thin and without pores or thickenings. The milk-tubes of certain species of *Euphorbia* differ from the type by being thick-walled and slightly porous. The content is a milky juice, mostly whitish, seldom yellow, as in celandine (*Chelidonium*), or reddish as in bloodroot. Milk-tubes occur as "ducts" or "cells," and are developed in different ways. The "ducts" are formed by parenchymatic cells arranged in rows, and of which the radial cell-walls become dissolved entirely. The "cells" are, on the other hand, single cells, which grow out into long and branched tubes similar in some respects to the so-called "hyphæ" of certain fungi.

The Fundamental Tissue.— This tissue comprises all the other tissues of the plant not referable to the epidermis, the mechanical, or the conductive tissue, and is as a rule composed of thin-walled, parenchymatic cells with distinct intercellular spaces. Its function is principally to prepare and store nutritive matters, hence the chlorophyll, the starch, and similar matters are contained in this tissue. Several types of fundamental tissue have been distinguished in the various plant-organs, such as the cortex in stems and roots; the pith in stems, but only occasionally in roots; the mesophyll with the palisade- and pneumatic-tissue in leaves; and finally the parenchymatic sheaths, which often surround the mestome-bundles as the endodermis, the mestome-sheath, etc.

The location of these various types of the fundamental tissue is as follows: The cortex, whose outermost layers are often designated as the "hypoderm," is in the stem located beneath the epidermis and borders inwardly on the mestome-bundles or on the mechanical tissue, supporting these. The cortex contains often ducts and cells with chrystals, and is in not a few instances traversed by aëriferous lacunes of quite considerable width, which prevail in aquatic plants. The cortex in the root occupies the same position, and its innermost layer is here constantly differentiated as an endodermis, bordering on the pericambium. The endodermis of both stem and root differs from the other strata of the cortex by the cells being prismatic and often quite long, by the cell-walls sometimes attaining a prominent thickening, and by the corky substance of the cell-wall.

In many respects the pith resembles the cortex, but is usually of a more regular and uniform structure, as a rule constituting the innermost portion of the central cylinder of stems. Mestome-bundles, ducts, lacunes, and chrystal-bearing cells may also be observed in the pith, but not so frequently as in the cortex.

A tissue corresponding in many respects to the cortex is the chlorophyll-bearing palisade- and pneumatic-tissue in leaves. The cells of the palisade-tissue are very thin-walled, rectangular, and placed vertically on the upper surface of the leaves; they contain chlorophyll in abundance. The pneumatic-tissue is located underneath the palisade-tissue and borders on the epidermis of the lower face of the leaf. It is of a very open structure on account of the frequently very irregular shape of the cells, which may vary from roundish to polyhedric or even stellate, a structure corresponding well with its function and its location near the lower epidermis, where the stomata are most numerous.

These tissues, briefly described above, are the most characteristic ones of plant-organs, but their mutual position in these organs offers not a few variations, hence it will be necessary to present a discussion of their occurrence as constituting the structure of roots, stems, and leaves.

The Anatomy of the Root.— The fact that the root is only slightly susceptible of modification in respect to its external structure is especially expressed by the great uniformity that prevails in its internal structure. Roots, however, are not always quite as uniformly developed as generally described, but very few botanists have paid much attention to their structural peculiarities. Some types of roots have been suggested,— for instance "nutritive," "attachment," "contractile," and "storage," — all of which possess a somewhat modified structure corresponding to their functions. But common to all roots are the following tissues: Epidermis, cortex, pericambium, and the conductive tissue.

The epidermis is as described above, but lacks the cuticle, at least partly, and the only hair-formations that occur here are the long, unicellular root-hairs, observable on nearly all young roots excepting at the apex of these, which is covered by the root-cap. The cortex consists of parenchymatic cells, frequently arranged in regular concentric rings; the outermost strata beneath the epidermis are often differentiated as a more or less thick-walled and persisting hypoderm, while the inner ones are usually thin-walled and liable to collapse radially or tangentially, thus giving rise to wide lacunes. The innermost layer of the cortex differs from all the others and represents the endodermis (*e* in Fig. 9), whose structure offers several excellent characteristics for its distinction from the adjoining cortical parenchyma and the pericambium (*p* in Fig. 5). Such characteristics may be expressed by the different manner in which the cell-walls are thickened, or by the presence of the peculiar dots named after Caspary, which are seldom lacking in thin-walled endodermis-cells. These dots, readily visible in transverse sections, are due to foldings of the cell-wall. Inside the endodermis is a layer, and commonly a single one, of usually thin-walled cells, called the pericambium or the pericycle. This tissue is a most important one, since it is capable of cell-division, and it is in this layer that all lateral roots of phanerogams become developed, and usually also the root-shoots. In ferns the lateral roots do not originate in this tissue, but in the endodermis. The pericambium surrounds the conductive tissue in roots

represented by strands of leptome and hadrome in alternation with each other, sometimes enclosing a central mass of conjunctive tissue, or a wide central vessel. The leptome is not as well differentiated as in the stem, and the vessels are arranged in radial groups of which the outermost are the oldest and generally known as the "proto-hadrome vessels." The position of the proto-hadrome is variable, since it is not unusual to observe some of the vessels bordering on endodermis, having thus broken through the pericambium, a structure not uncommon in grasses and sedges. The normal position of these earliest developed vessels is, however, inside the pericambium. But whatever the position may be of these primordial vessels, the development of the hadrome is in roots constantly centripetal in contrast to the stem; the central arrangement of the conducting elements in the roots offers also an excellent distinction between root- and stem-structure, besides the tangential and alternating position of the leptome and hadrome. It is a well-known fact that roots of trees and certain herbaceous plants increase in thickness. This is due to the development of a cambium, a formative tissue, inside the leptome, but forming an arch outside the proto-hadrome. In general this cambium behaves like that of the stem, forming hadrome inwardly, leptome and mechanical tissue outwardly, thus the structure of such roots becomes exactly like that of a stem unless the central portion is still preserved. For in the root the centre must be occupied by three or more radiating primordial vessels instead of a pith.

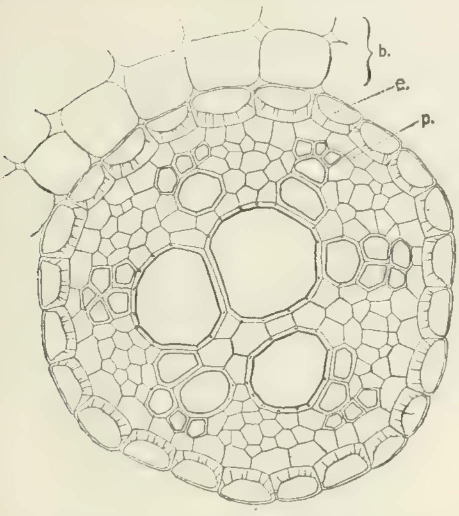


FIG. 9.— Cross-section of the root of *Commelina: b*, the cortex; *e*, endodermis; *p*, the pericambium; the six rays of vessels alternate with six groups of leptome.

The Anatomy of the Stem.— The minor structure of the stem of the above- and underground differs materially from that described as characteristic of normal roots, even if the tissues themselves are much the same. There is an epidermis, a cortex, a mechanical- and conductive-tissue besides a pith, but no pericambium. The stem, however, exhibits a much larger plasticity than the root, and the numerous modifications that occur in respect to the mere external structure are usually accompanied by a corresponding variation in its interior. Marked distinctions are noticeable in stems when we compare the herbaceous with the woody, the annual with the perennial, the terrestrial with the aquatic, and the aërial with the subterranean,— distinctions that have been very extensively studied and have rendered it possible to identify fragments of such stems merely by the aid of the microscope.

When compared with the root, the presence of a pith is characteristic of the stem, while on the other hand a pericambium is observable only in roots. The minor structure of the stem is thus very variable, but may be described more generally as follows: The epidermis consists mostly of a single layer; the outer cell-wall always possesses a more or less distinct cuticle, and the cells may be extended into hairs of very different aspect and functions as already described. When the epidermis is not sufficient to protect the inner tissues,— as, for instance, in perennial stems or such as increase in thickness,— a cork develops either in the epidermis itself or in the cortical parenchyma. The cortex is often prominently represented by numerous layers of parenchymatic tissue in which bundles of stereome and mestome frequently occur, in addition to which lacunes and ducts are commonly observed. The innermost layer of the cortex is usually modified as an endodermis (*End*, in Fig. 10), surrounding the central mass of conductive tissue. The mechanical tissue occurs either as isolated strands or as a partial or complete covering of the mestome-bundles. The arrangement of the mechanical tissue is extremely variable and the monocotyledonous plants are especially instructive in respect to this particular tissue. The conductive tissue represented by the mestome-bundles contains the elements as described above, and most frequently each bundle consists of both leptome and hadrome, usually arranged radially with the leptome as the outermost. A very delicate tissue is observable between both

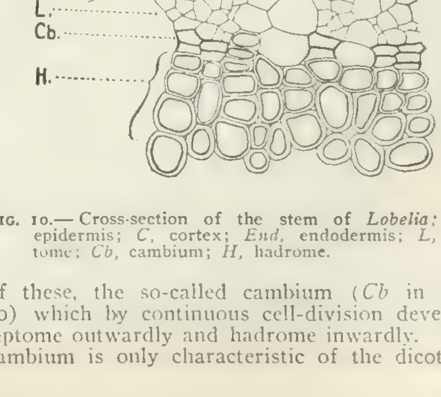

FIG. 10.— Cross-section of the stem of *Lobelia: Ep*, epidermis; *C*, cortex; *End*, endodermis; *L*, leptome; *Cb*, cambium; *H*, hadrome.

of these, the so-called cambium (*Cb* in Fig. 10) which by continuous cell-division develops leptome outwardly and hadrome inwardly. The cambium is only characteristic of the dicotyle-

donous plants. When the cambium occurs between the leptome and the hadrome it is called intrafascicular in contrast to the interfascicular,

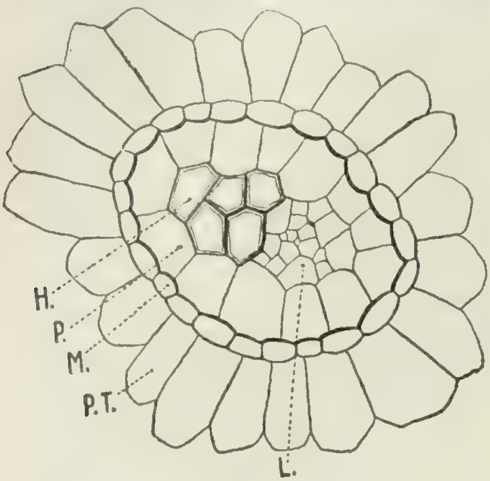

FIG. 11.— Cross-section of the leaf of *Cyperus*, showing a mestome-bundle surrounded by palisade-tissue (*PT*): *M*, the mestome-sheath; *P*, the inner parenchyma-sheath; *H*, the hadrome; *L*, the leptome.

located between the mestome-bundles, thus the cambium in such plants constitutes a closed ring. The mestome-bundles do not always exhibit this radial structure where the leptome is located outside the hadrome, a type that is called collateral (Figs. 11 and 12), but some modified structures have been described, namely the "bicollateral" and the "concentric." The bicollateral are characterized by the presence of leptome on both sides of the hadrome, outside and inside, and this structure has been observed in several of the dicotyledonous orders, for

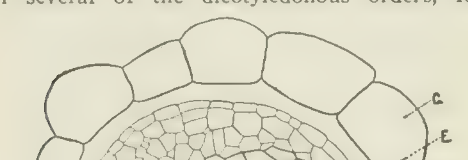

FIG. 12.— Cross-section of a mestome-bundle from the leaf-stalk of a fern (*Polypodium*): *C*, the innermost layer of cortex; *E*, endodermis surrounding the conductive tissue with the vessels in the middle.

instance in the *Cucurbitaceæ* and *Solanaceæ*. The latter type, the concentric, represent a singular arrangement of the leptome and hadrome, the one being surrounded by the other; when the hadrome surrounds the leptome the bundle is called "peri-hadromatic" (Fig. 13), while in the peri-leptomatic bundle the hadrome occupies the central space (Fig. 12). These types of concentric bundles are not so very frequent, but the perihadromatic are, however, quite characteristic of the rhizomes of the majority of the monocotyledons. The perileptomatic bundles are very rare among the phanerogams, but constitute the only form of mestome-bundles in ferns and lycopods.

When we consider the general arrangement of the mestome-bundles in transverse sections of mono- and dicotyledons, we notice a striking difference by the fact that in the former these bundles are scattered without any order, while they form concentric rings in the latter.

While thus these systems of tissues exhibit many variations in the stems, the last tissue, the pith, is almost uniformly developed as a central parenchyma, and as a rule is always

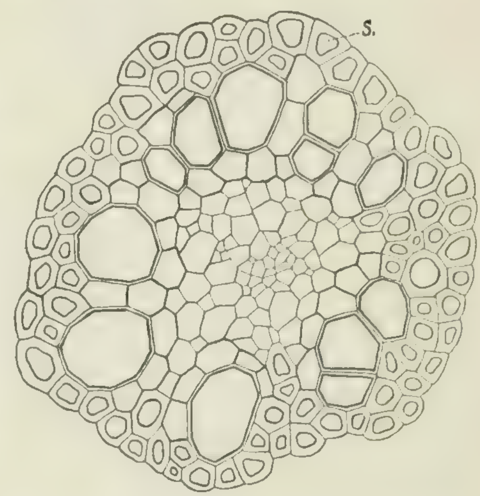

FIG. 13.— Cross-section of a mestome-bundle from the rhizome of a sedge (*Carex incurva*): *S*, the stereome, surrounding the conductive tissue with the leptome in the middle.

present in stems. The thickness of various underground stems, such as tubers, is due to the prominent development either of the pith or of the cortex, in which starch and similar nutritive matters may be stored.

The Anatomy of the Leaf.— The manifold variation exhibited by leaves corresponds also with certain modifications of the internal structure, but to a much less extent than observable in stems. The various functions performed by the leaves do not require such great internal modification as is necessary to the stem, even if the leaves exhibit a metamorphosis of no small importance. The stem-leaves and the floral leaves naturally show conspicuous anatomical distinctions, and the fleshy leaves of bulbs are of course very different in structure from the thin, scale-like leaves of tubers and stolons. However, the principal structure, such as is exhibited by the relative development and arrangement of the main tissues, for instance the mesophyll (the chlorophyll-bearing parenchyma

including the palisade- and the penumatic-tissue), the stereome, and the conductive tissue, is not very variable in leaves when we consider the enormous variation in the shape and size of their outline. In the leaves the epidermis is perhaps the tissue that is subject to the most conspicuous modification, which is especially noticeable in the development of the cells when examined on both surfaces of the leaf, above and between the nerves. The various arrangements of the stomata often cause a modification of the surrounding strata, which is less pronounced in the stems. Thus the epidermis, when examined superficially, exhibits several distinct forms of cells, rectangular, polyhedric, or with the outline very prominently modulate (Fig. 5). The covering with hairs is especially characteristic of leaves, and several types of these may be found to occur on the same leaf. The cuticle is usually very distinct, and renders by its various consistence the most essential protection to the leaf while performing its functions. Besides the epidermis, corky layers may be developed, at least locally, in leaves which

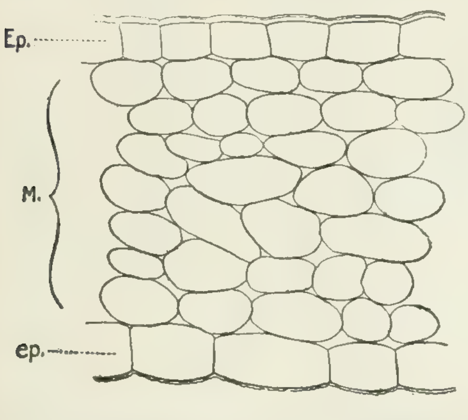

FIG. 14.— Cross-section of the leaf of *Obolaria: Ep*, epidermis of upper surface; *ep*, epidermis of the lower; *M*, the mesophyll.

persist for several seasons; for instance, the evergreen, in which the outer cell-wall of epidermis often becomes very considerably thickened.

The mesophyll is generally differentiated as a palisade- and a pneumatic-tissue, the former located on the upper face of the leaf, just beneath the epidermis, while the latter occupies the lower portion. In some leaves the mesophyll is not differentiated into these two tissues, but only as a homogeneous (Fig. 14) tissue; such leaves are called «isolateral» in contradistinction to the others, the «bifacial.» Otherwise the mesophyll possesses the same forms of reservoirs, ducts, and lacunes as are characteristic of the cortex.

The mestome-bundles are generally collateral with the hadrome located above the leptome, and we find in the leaves the same mechanical support as observed in the stem. But while the mestome-bundles of the stem may show such modifications as «bicollateral» or «concentric,» they lose this peculiarity as soon as they enter the leaves, in which they occur only as collateral.

The leaf-structure thus possesses less variation than that of the stem. if we compare the relative development and the arrangement of the tissues, especially of the mesophyll, the stereome, and the mestome. The main variation seems to lie in the epidermis, and becomes especially noticeable in the comparison of leaves of plants that grow under diverse conditions,— of terrestrial and aquatic plants, for instance. Among the former the desert-plants are known to possess highly complicated structures, which naturally are expressed by the epidermis and the mesophyll rather than by the other elements. But considered as a whole, the leaves show less modification of the inner tissues than the stem, and when some prominent variations are found to occur in leaves these are generally observable also in the stems of the same plants.

The object of the study of plant-anatomy is to ascertain the structure of the various plant-organs, and to bring this in connection with the functions performed by these, thus physiological botany must necessarily be preceded by anatomical studies. But in later years plant-anatomy has been extended still further, and a special branch of this science, «plant-anatomy,» is now recognized as the «anatomical method» by which modifications in structure are brought in connection with the systematic position of the plants. And anatomical investigations have proved that certain precise characteristics do exist in most of the natural orders; thus these, their genera, and in many instances even their species, may be distinguished simply by a few anatomical characters.

This method was founded by the French botanist Mirbel, who was followed, but many years later, by Vesgne and Radlkofer, whose works constitute the real foundation of this particular branch of anatomy. In later years the anatomical method has been studied very extensively, but is of course of less importance than the former, where the structure is brought in connection with physiological problems, the life of the plant under various conditions of environment.

THEO. HOLM,
Expert Botanist, Washington, D. C.

Anaxag'oras, a Greek philosopher: b. in Clazomenæ, in Ionia, about 500 B.C.; d. in Lampsacus, about 428. Settling at Athens, his pupils included Pericles, Euripides, and Socrates. In middle life he was publicly charged with impiety and condemned to death, but the sentence was commuted to perpetual banishment. Anaxagoras held that there was an infinite number of different kinds of elementary atoms, and that these, in themselves motionless and originally existing in a state of chaos, were put in motion by an eternal, immaterial, spiritual, elementary being, from which motion the world was produced.

Anaxarchus, a native of Abdera, who was a friend and counselor of Alexander. He was put to death by Nicocreon, prince of Cyprios.

Anaximan'der, a Greek philosopher, mathematician, and astronomer: b. in Miletus 611 B.C.; d. 547. The substance of his philosophical teaching is that the source of all things is an undefined substance infinite in quantity. According to his theory the universe is a series of concentric cylinders surrounding the cylindrical

earth. Anaximander occupied himself much with mathematics and geography, and to him are ascribed the invention of geographical maps, the first application of the *gnomon* or style fixed on a horizontal plane to determine the solstices and equinoxes, and the discovery of the obliquity of the ecliptic.

Anaximenes of Lampsacus, a Greek historian: b. in Lampsacus, Asia Minor, about 340 B.C. To him is attributed the 'Ars Rhetorica ad Alexandrum' found among the writings of Aristotle. Only fragments of his histories of Philip of Macedon, Alexander, and Greece remain.

Anaximenes of Miletus, a Greek philosopher: b. in Miletus, and flourished about 550 B.C. He affirmed that air was the first principle of all things. Finite things were formed from the infinite air by compression and rarefaction produced by eternally existent motion; and heat and cold resulted from varying degrees of density of the primal element.

Anaya, à-nä'yà, **Pedro Maria,** a Mexican commander: b. in Huichapan 1795; d. 1854. Entering the army in 1811 he attained the rank of brigadier-general in 1833. He held several cabinet positions, was acting president of Mexico for a few weeks in 1847, and at the time of his death was postmaster-general under Santa Anna.

Ancachs, a department of northern Peru, extending from the Andes to the Pacific: capital, Huaraz. Agriculture and cattle-raising are the chief occupations, the silver-mines in the mountains being but ineffectively worked. Area, 17,-405 square miles. Pop. about 429,000.

Ancæus, the name of two of the Greek Argonauts, one the son of Poseidon and steersman of the Argo, the other a son of the Arcadian Lycurgus. Each was killed by a wild boar.

Ancelot, Jacques Arsène François Polycarpe, a French novelist, dramatist, and poet: b. Havre, 9 Feb. 1794; d. Paris, 7 Sept. 1854. His tragedy, 'Louis IX.,' brought him a pension in 1819, but he lost it through the revolution of 1830. He produced pleasing verses, epigrammatic satires; an epic, 'Marie de Brabant' (1825); a novel, 'L'Homme du Monde' (1829), as well as other works, but 'Louis IX' remains his most important achievement. His wife, MARGUERITE VIRGINIE CHARDON, b. Dijon, 15 March 1792; d. Paris, 21 March 1875, wrote novels and plays sometimes with him, but also independently, and won some attention as an artist.

Ancestor, one who has preceded another in a direct line of descent; an ascendant, a former possessor; the person last seised. Termes de la Ley; 2 Shars. Bl. Com. 201. In the common law, the term is understood as well of the immediate parents as of those that are higher; as may appear by the statute, 25 Edw. III., *De natis ultra mare*, by the statute 6 Rich. II. c. 6, and by many others. But the civilians' relations in the ascending line, up to the great-grandfather's parents, and those above them, they term *majores*, which common lawyers aptly expound *antecessors* or ancestors, for in the descendants of like degree they are called *posteriores*. Cary, Litt. 45. The term ancestor is applied to natural persons. The words predecessors and successors are used in respect to the persons composing a body corporate. See 2 Bl. Com. 209; Bacon, Abr.; Ayliffe, Pand. 58; Reeve, Descents.

Ancestor-Worship. See MAN.

Anchieta, àn-shyä-tà, **Jose de,** a Portuguese missionary in Brazil: b. Laguna, Teneriffe, 1533; d. 1597. He was a Jesuit and founded in Brazil the first institution for the conversion of the inhabitants. He was the author of 'Natural Productions of Brazil.'

Anchisaurus, a carnivorous dinosaur of the Triassic period. It has many primitive characteristics, notably small size, four complete toes in the hind foot and five in the fore foot.

Anchises, a legendary hero of Troy, to whom Venus, in the guise of a Phrygian shepherdess, bore a son, Æneas. At the burning of Troy Æneas carried his father away on his shoulders, and their voyage to Sicily is described in Virgil's 'Æneid.'

Anchitherium. See FOSSIL; HORSE.

Anchor, a heavy instrument of iron, intended to be dropped from a ship to the sea-bottom, to hold her in a desired position. It usually consists of a shank, having at one end a ring, to which the cable is fastened with a cross-piece or stock, and at the other end two arms with blades at the end, called flukes. In one form of anchor the stock is not a cross-piece in the sense of lying transversely to the direction of the arms, but lies in the same direction. In the Homeric times large stones were used for anchors; afterward they are said to have been sometimes of wood loaded with lead. In some places baskets full of stones or sacks filled with sand were employed for the same use. All these were let down by cords into the sea, and by their weight stayed the course of the ship. Among the Greeks of later times anchors were composed of iron. Sometimes there was only one tooth or fluke, but generally there were two. Anchors with two flukes appear from ancient monuments to have been much the same as those used as present, but the transverse piece of wood fastened to the shank (the stock) is wanting in all of them. Every ship had several anchors, one of which, surpassing all the rest in bigness and strength, was peculiarly termed, in Greek, *hiera*, and in Latin *sacra*, and was never used but in extreme danger; whence *sacram ancoram solvere* is proverbially applied to such as are forced to their last refuge. When an anchor of the usual form is let fall from the vessel, it generally strikes the bottom with the crown or curve of the arms, and then falls over on one of the ends of the stock, the arms lying flat on the ground. In this position it cannot bite, so that it has to be canted or turned over till the stock lies flat, and the point of one of the flukes (the bill or peak) rests on the ground. The canting is effected by the vessel pulling at the cable, and the longer the stock and the shorter the arms the less is the force required to perform the operation; for this reason the stock is always made longer than the arms. The anchor will now either drag or penetrate the ground, the readiness with which it does the latter depending on the sharpness of the bill, the angle at which the fluke rests on the ground, and of course the nature of the bottom. Formerly the arms used to be rigidly at-

tached to the shank of the anchor; but in 1838 Mr. Porter took out a patent for an anchor of a new construction (though the principle was known before, however), in which the arms were movable around a pivot at the end of the shank, the plane of their movement being perpendicular to the direction of the stock. The advantages of this anchor are, that there is almost no possibility of fouling it,— that is, of the cable becoming entangled with one of the arms; it cannot lodge on the stock end; it presents no upper fluke to injure the vessel to which it is attached, or others, in shoal water (since the swivel movement enables the peak of the upper fluke to come close to the shank when the anchor is fixed); it is not so liable to break, is more conveniently stowed on board, etc. This form of anchor as improved by Trotman is now largely used in the merchant service. In the navies both of Great Britain and of foreign countries the anchor perhaps most commonly employed is the admiralty anchor with fixed arms, the chief recommendation of which is the excellence of its proportions. Another favorite is Rodgers', the chief peculiarity of which is its small flukes. The inventor claims for this anchor that it holds the ground better than those with large flukes. Another excellent anchor is that patented by a Frenchman named Martin. In his anchor the stock lies in the same direction as the arms, the consequence of which is that when the anchor reaches the ground it inevitably falls flat, with both stock and arms resting on the bottom. The arms are capable of turning in a socket through an angle of 30° in such a manner that when the anchor is lying flat on the ground the flukes of both arms may sink into the ground at an angle of 15°. The weight of the arms and the pull of the vessel cause them to do this. It will be understood that the flukes are not, as in other anchors, perpendicular to the direction of the arms, but lie in the same direction. Besides holding the ground more firmly than any other anchor of equal weight, this anchor has the advantages of being free from liability to foul and easily stowed. The latter circumstance particularly recommends it for use in unmasted turret ships, almost all of which are equipped with it.

The different anchors carried by a ship are called bower, sheet, stern, and kedge anchors. The bower anchors are so called from their being stowed in the bow. When one bower anchor is heavier than the other it is called the best bower and is stowed on the starboard side. Sheet anchors are stowed in the waist of the ship as far forward as convenient. The stream anchor is used in a river or sheltered place where a large anchor is not required. The stern anchor is stowed in the stern, and is employed with a bower anchor where there is no room for a vessel to swing with the tide. The kedge anchor is used to warp a ship from place to place; that is, the anchor is carried to a distance in a boat, and the ship is then pulled up to it by means of the cable. A large ironclad carries eight anchors: two bower, two sheet, and two kedge anchors, with one stream and one stern anchor. The anchor is said to be a-peak when the cable is perpendicular between the hawse and the anchor; and to come home when it does not hold the ship. To shoe an anchor is to fix boards upon the flukes so that it may hold better in a soft bottom. Riding at anchor is the state of the vessel when moored by the anchor or anchors. Dropping or casting anchor is letting it down into the sea. Weighing anchor is raising it from the bottom. A mooring anchor is a stationary anchor in a harbor or roadstead, with a buoy attached to it by a cable, enabling a ship to moor by simply fastening itself to a ring-bolt on the buoy. These anchors should not project above the bottom, or the ship may receive injury by grounding on them. Mooring anchors are of various kinds, and in some cases a heavy block of stone or cast iron serves as such. One of the most powerful mooring anchors yet invented consists of a wrought-iron shaft with a pointed screw end, and near the lower end a cast-iron screw flange 3½ feet in diameter. The anchor is screwed down into the solid ground, and its holding power is more than equal to that of a cast iron anchor weighing 7 tons. The making of anchors used to be a most formidable piece of smith work, but it has been much facilitated by the invention of the steam hammer. The shank of a large anchor, nearly 20 feet long and 10 or 12 inches thick, requires to be built up of a number of bars of iron which are then welded together. Crucible steel is now to some extent used for anchors.

Anchorage, a suitable place for anchoring. A good anchorage should have a soft bottom and a depth of from 10 to 20 fathoms. When deeper than this the cable bears too nearly perpendicular and is apt to drag up the anchor. The length of cable paid out by a ship in anchoring in ordinary weather is about three times the depth of the water. Anchorage also means dues paid by a vessel anchoring. As a rule a ship sheltering from stress of weather and not discharging cargo at the place where it anchors is not required to pay dues, but shore-dues are payable whether a ship anchors or not.

Anchorite, Anchoret, or **Anachoret,** one who has renounced the world and retired into a seclusion remote from inhabited places. The desire is not distinctively Christian: it manifests itself in all religions and in all ages. Anchorites of various Hindu ascetic sects are at present to be found among the jungles and hills of India, and the Orient has always been a land of them. The peculiarity of the ancient anchorites was that, though retiring for solitude to the wilderness, they lived there in fixed abodes, generally caves or hovels, in place of wandering about. When they did travel they slept wherever night overtook them, so that visitors might not know where to find them. They were most numerous in the Egyptian desert, where they lived on roots and plants, believing that to afflict the body was the best method of spiritually benefiting the soul. The most of them were laymen. There were also female anchorites. These first arose, it is said, about the middle of the 3d century; in the 7th the Church extended its control over them, ultimately throwing difficulties in the way of anyone who wished to adopt such a mode of life.

Anchovy, an-cho'vi (of uncertain origin, perhaps literally a dried or pickled fish, from Basque, *antzua*, dry), a small, richly flavored, herring-like fish (*Engraulis encrasicholus*), of the family *Engraulididæ*. It is caught abundant-

ly along the sea-coasts of southern Europe when coming in from the deep sea to spawn in early summer. The Mediterranean fishers in particular salt and dry it in large quantities for export. Closely allied species are found on the eastern and western coast of America and off southern Asia. A Californian species (*Engraulis mordax*) is extremely abundant in large schools and is a valuable food fish. In general, anchovies are 5 to 7 inches long, shaped like herrings, and have a pointed head and projecting upper jaw.

Anchovy-pear (*Grias cauliflora*), a tree of the natural order *Myrtaceæ*, found in moist districts of the West Indies. It grows to the height of 50 feet, has oblong leaves 2 or 3 feet long, and large white blossoms carried on short peduncles. Its fruit, somewhat larger than a hen's egg, is pickled and eaten like the mango, which it strongly resembles in taste.

Anchusa. See ALKANET.

Anchylosis, ăn-kĭ-lō'sĭs. See JOINTS.

An'chylo'stomiasis, a disease due to the presence of an intestinal parasite, the *Anchylostomum duodenale* (*Uncinaria duodenalis*). This parasite lives in the upper portion of the small intestine, where, by means of a series of tooth-like hooks about the mouth, it attaches itself to the mucous membrane. It is particularly prevalent among Italian and Polish laborers, especially among those who work in confined spaces, as mines, tunnels, etc.

The chief symptoms are those due to the loss of blood which the worm constantly sucks from the wall of the intestine. Gastro-intestinal disturbance, progressive anæmia, diarrhœa, and colicky pains with shortness of breath and swelling of the limbs are among the important symptoms. The diagnosis can be made by means of a microscopical examination of the fæces, in which the eggs are found, and also by the microscopical examination of the blood. Careful attention given to the drinking water is one of the most important prophylactic measures. See PARASITE.

Ancient Demesne, a term employed in English law to denote ancient estates belonging to the crown. They are mentioned in Domesday Book as *Terræ Regis*.

Ancient Lights, a term denoting windows so long existent that they have obtained a right to the light entering them, and cannot be interfered with by the owner of the property whence the light enters. Rights of this nature cannot commonly be acquired by prescription in the United States. Ancient lights in England are now regulated by a statute calling for but 20 years' existence to create the right.

Ancient Mariner, Rime of the, a celebrated poem (1817) by Samuel Taylor Coleridge. It is one of the most original poems in the English language. A wedding guest on his way to bridal festivities is stopped by an old man, the Ancient Mariner. The Ancient Mariner describes his voyage, how his ship was locked in the ice, and how he shot with his cross-bow the tame albatross, the bird of good omen which perched upon the vessel. The entire universe seemed stunned by this wanton act of cruelty; and the albatross is hung around the neck of the Ancient Mariner. A spectre ship appears, and the crew die, leaving the graybeard alone. After a time he is moved to prayer, whereupon the evil spell is removed. The albatross sinks into the sea, and the Mariner's heart is once again a part of the universal spirit of love. The weird ballad is capable of many interpretations, and in its small compass it contains a tragedy of remorse and of redemption through repentance.

Ancient Order of Hibernians. See HIBERNIANS, ANCIENT ORDER OF.

Ancient Régime, The, an historical work by H. A. Taine (1875), a masterly study of the France which, after 1,200 years of development, existed in 1789, of great value for the history of France and for judgment of the future of the French Republic. Taine's brilliant style and picturesque narrative, his philosophical contemplation of data, and his keen reasoning, have never been more strikingly exhibited than here.

Ancient Rome in the Light of Recent Discoveries, an archæological work by Rodolfo Lanciani: b. 1847. In his character of official investigator Prof. Lanciani has grouped in this volume various illustrations of the life of ancient Rome as shown in its recovered antiquities. From these he reads the story of the wealth, taste, habits of life, ambitions, and ideals of a vanished people.

Ancients, Council of, the upper one of two branches of the legislative body of France, 1795–99. It included 250 members and its function was to consider measures submitted by the lower branch, the Council of Five Hundred.

Ancile, a shield reported to have fallen from heaven in the time of Numa. It was believed to be the shield of Mars; and as the prosperity of Rome was held to depend upon its preservation, 11 facsimiles of it were made, that anyone wishing to steal it might not know which to take. It is conjectured to have been originally a lump of meteoric iron.

Ancillon, än'sē'yon, **Johann Peter Friedrich,** a German historian of French extraction: b. Berlin, 30 April 1767; d. there, 19 April 1837. Besides 'Mélanges of Literature and Philosophy' (1801) he was the author of a 'View of the Revolutions of the Political System of Europe since the 15th Century' (1803–5), which secured him the post of royal historiographer. From 1832 till his death he was minister of foreign affairs.

Ancona, Allessandro d', a prominent Italian critic and philologist: b. Pisa, 1835, and from 1860 a professor of literature in the University of Pisa. Among his many works are 'I Precursori di Dante' (1874); 'Origini del Teatro in Italia' (1877); 'La Poesia Popolare Italiana' (1878); 'Varietà Storiche e Lettarie' (1883–5); 'Studi sulla Letteratura Italiana de' Primi Secoli' (1884).

Ancona, an Italian province of the kingdom of Italy, between Pesaro ed Urbino on the north, Macerata on the south, and the Apennines and Adriatic on the west and east; area, 736 square miles. It is a mountainous region watered by the rivers Cesano, Esino, and Musone, and produces grain, wine, oil, olives, silk, and fruit. Capital, Ancona. Pop. (1894) 273,941.

Ancona, an important Italian port on the Adriatic, the capital of the province of the same name. Its site is an amphitheatre between two headlands, and on its ancient mole, designed by Trajan, is a triumphal arch by Apollodorus. The modern mole is adorned by a triumphal arch by Vanvitelli. Among important buildings are the cathedral of St. Cyriac dating from the 11th and 12th centuries, a 13th-century town hall, and a museum. Sugar-refining, ship-building, and manufactures of silk, paper, and sail-cloth are the main industries. A United States consul is stationed here. The city is said to have been founded by Syracusans fleeing from the persecutions of the Elder Dionysius. Pop. (1901) 57,000.

Ancre, äɴ'kr, **Concino Concini, Marshal and Marquis d',** a Florentine who went to France in 1660, where he obtained rapid promotion, more especially after the assassination of the king (1610). Successively governor of Normandy, marshal of France, and last of all prime minister, he was thoroughly detested by all. At last a conspiracy was formed against him and he was shot dead on the bridge of the Louvre in 1617.

Ancud, a Chilian port, capital of the province of Chiloe. It is situated on the island of Chiloe, about 580 miles from Valparaiso, a line of steamships connecting the two. First settled in 1768, it was the last place surrendered by the Spaniards to the Chilians in 1826. Pop. (1895) 3,182.

Ancus Marcius, the fourth king of Rome: b. 638 B.C.; d. 614 B.C. The son of Numa's daughter, he attempted to imitate his grandfather by reviving the neglected observances of religion. His peaceful pursuits were disturbed by the Latins, whom he subdued and caused to be brought to Rome, where he assigned them the Aventine to dwell upon. These conquered Latins, according to Niebuhr, formed the original *plebs.* He fortified the Janiculum against Etruria, connecting it with the city by the wooden bridge across the Tiber known as the Sublician; dug the ditch of the Quirites; constructed the harbor of Ostia; and built the first Roman prison of which there is any record.

Ancy'ra. See ANGORA.

An'da, a genus of plants of the natural order *Euphorbiaceæ.* The *A. brasiliensis,* the single species, is an inhabitant of Brazil. The wood is spongy and light, the flower yellow and large, and the fruit a gray nut which encloses two kernels in a double rind. The fruit is strongly purgative and is used by Brazilians as a remedy in cases of indigestion, jaundice, and other diseases. Oil is pressed from these kernels, with which the natives anoint their limbs. It is said to be a good drying oil and excellent for painting. The rinds of the fruit, thrown into ponds, destroy the fish.

Andalusia, ăn'dȧ-lōō'zĭ-ȧ (Spanish, *Andalucia*), a district of southern Spain, celebrated for its fertility and picturesque beauty; bounded north by Estremadura and New Castile, east by Murcia, south by the Mediterranean Sea, and west by Portugal and the Atlantic. Length east and west about 310 miles; average breadth about 120; area about 33,650 square miles. It is traversed throughout its extent by ranges of mountains. The Sierra Morena runs along its northern border, and in the southeast rise the mountains of Granada and the Ronda, including numerous sierras, and among them those of the famous Sierra Nevada. Many summits of the latter ranges are covered with perpetual snow; the Mulahacen rising 11,678 feet, and the Picacho de Veleta 11,378 feet above the sea. All the mountains abound with mineral wealth, yielding chiefly copper, cinnabar, and lead, as well as some silver, copper, and coal. Mines have been opened recently by English companies, especially in the province of Huelva in the west, where the Tharsis and Rio Tinto copper mines are situated. The principal river of Andalusia is the Guadalquivir, which rises in the east part of the province of Jaen, near Carzola, and thence flows west-southwest, and below Seville south-southwest, entering the sea at San Lucar. Its principal affluents are the Guadalimar, Guadiato, and Xenil. The rivers south of the Sierra Nevada are quite insignificant. The basin of the upper Guadalquivir lies at an elevation of from 500 to 1,500 feet, and consists mainly of saline wastes and other sterile tracts. The lower basin presents sharp contrasts: around Cordova and Seville luxuriant gardens; on the Xenil a desert without a drop of water; on the left bank of the lower Guadalquivir the extensive marshy district of Marisma; and stretching from the mouth of the Guadalquivir to that of the Rio Tinto, a sandy depression (Arenas Gordas) partially clothed with pine-woods. The vegetation is of the character peculiar to the extreme south of Europe and the north of Africa. Wheat, maize, barley, many varieties of fruit, grapes, honey, silk, and cochineal form important articles of culture. A large portion of the soil is in pasture. The horses are the best breed in the Peninsula; the bulls of Andalusia are sought for bull-fighting over all Spain; sheep are reared in vast numbers, and bear an abundance of good but not fine wool; and the hogs reared on the acorns of the mountain forests furnish hams unsurpassed in any part of Europe. The chief manufactures are woolens, silk, and leather, and are by no means extensive. The name Andalusia is commonly taken to have been originally Vandalusia, the land of the Vandals. The population was in 1897 about 4,000,000.

Andalu'site, a native anhydrous silicate of aluminum, first discovered in Andalusia. Its chemical formula is Al_2SiO_5, and it crystallizes in the orthorhombic system. It usually occurs in coarse crystals, prismatic in form, and nearly square. Its hardness is 7.5, at least on the basal face, and its specific gravity about 3.18. Andalusite is commonly subtranslucent and varies greatly in color. Some specimens are strongly pleochroic, changing from olive green to blood red according to the angle at which the incident light strikes them. A variety known as chiastolite contains carbonaceous impurities distributed through the prismatic crystal according to a definite geometric plan, so that a transverse section of the crystal presents a curious tesselated or cruciform appearance. A variety from eastern Finland has been called «maltesite,» from the regularity of the Maltese cross it exhibits when seen in section. Andalusite is found in many parts of Europe, usually in schist or gneiss. Fine specimens also come from the province of Minas Geraes, Brazil. In the Unit-

ed States it occurs in Maine, New Hampshire, Vermont, Massachusetts, Connecticut, Pennsylvania, South Dakota, and California.

Andamans, ăn'dá-manz, a chain of volcanic lands on the east side of the Bay of Bengal, consisting of four principal islands called the North, Middle, South and Little Andamans, with a number of islets. Middle Andaman, the largest, is about 50 miles long and 15 or 16 miles broad. North and South Andaman are each about 44 miles long, and the former has near its east coast a mountain called Saddle Peak, about 2,400 feet high. The vegetation on the islands is very luxuriant — so much so as to render parts almost impenetrable. The aborigines, about 10,000 in number, are small (generally much less than 5 feet), well formed, and active, skilful in the use of the bow and in the management of their canoes, and excellent swimmers and divers. These islands have been occupied since 1858 as a penal colony by the British government of India, the settlement being at Port Blair on South Andaman. Here cultivation has been introduced, rice, coffee, nutmegs, etc., being grown, and the neighboring hills now afford pasturage for numerous cattle. A good deal of thoroughly cleared land has been given over to ticket-of-leave men to cultivate. The coffee produced is very well flavored, fruits thrive excellently, and the pineapples of Port Blair have already a good reputation in India. Edible birds' nests are found in large numbers. The natives in the vicinity of the settlement have been taken under the protection of the government, and have become to some extent civilized. The climate is moist, but fairly healthy. Area, 2,700 square miles. Pop. of Port Blair settlement (1902) about 20,000, of which four fifths are convicts.

Andersen, ăn'der-sen, **Hans Christian,** a Danish novelist, poet, and writer of fairy tales: b. in Odense, 2 April 1805; d. Copenhagen, 4 Aug. 1875. He learned to read and write in a charity school, whence he was taken when only nine years old, and was put to work in a manufactory in order that his earnings might assist his widowed mother. In his leisure time he eagerly read national ballads, poetry, and plays, and wrote several tragedies which he failed to get accepted. His abilities at last brought him under the notice of Councilor Collin, a man of considerable influence, who procured for him free entrance into a government school at Slagelse. From this school he was transferred to the university and soon became favorably known by his poems. His first considerable work, 'A Journey on Foot from Holmen's Canal to the East Point of Anger,' was published in 1828, the year of his admission to the university. Through the influence of Oehlenschläger and others he received a royal grant to enable him to travel, and in 1833 he visited Italy, his impressions of which he published in 'The Improvisatoren' (1835), a work which rendered his fame European. The scene of his following novel, 'O. T.,' was laid in Denmark, and in 'Only a Fiddler' he described his own early struggles. In 1853 appeared the first volume of his 'Fairy Tales,' of which successive volumes continued to be published year by year at Christmas, and which have been the most popular and widespread of his books. Among his other works are 'Picture-books without Pictures,' 'A Poet's Bazaar,' and a number of dramas. In 1845 he received an annuity from the government. He visited England in 1848 and acquired such a command of the language that his next work, 'The Two Baronesses,' was written in English. In 1853 he published an autobiography under the title, 'My Life's Romance,' an English translation of which, published in 1871, contained additional chapters by the author, bringing the narrative to 1867. Among his later works are, 'In Sweden' (1849); 'To Be or Not to Be' (1857); 'Tales from Jutland' (1859); 'The Sand-hills of Jutland' (1860); 'The Ice Maiden' (1863); 'In Spain' (1863).

Anderson, Edwin Hatfield, American librarian: b. Zionsville, Ind., 27 Sept. 1861. He was graduated from Wabash College 1883; librarian Carnegie Free Library, Braddock, Pa., for three years; organized and became first librarian of Carnegie Library, Pittsburg, 1895. He is the author of numerous papers on library economy in 'Library Journal.'

Anderson, George B., an American Confederate soldier: b. Wilmington, N. C., 1831; d. 16 Oct. 1862. He was graduated from West Point in 1852, and in 1855 obtained his commission as first lieutenant in the United States army, and served as regimental adjutant after 1858. Entering the Confederate service in 1861, he was made a brigadier-general and placed in command of the North Carolina coast defenses. While leading a brigade at the battle of Antietam, 17 Sept. 1862, he received the wound which caused his death.

Anderson, Henry John, an American educator: b. New York, 6 Feb. 1799; d. Lahore, Hindustan, 19 Oct. 1875. Was graduated from Columbia College, 1818; M.D. College of Physicians and Surgeons, 1823. Professor of mathematics and astronomy at Columbia, 1825-50; trustee 1851, and professor emeritus 1866; geologist to the Dead Sea expedition under Lieut. Lynch; member of the scientific expedition to observe the transit of Venus, 1873. He died while exploring the Himalayas. He early became converted to the Catholic faith and was active in promoting its interests in New York city. The United States government published his 'Geology of the Expedition to the Dead Sea' (1848).

Anderson, James, a Scottish agricultural economist: b. Hermiston, in Midlothian, Scotland, 1739; d. Isleworth, 1808. When scarcely 20 years of age he invented the small two-horse plow without wheels, known as the Scotch plow. Four years later he left Hermiston and rented a large moorland farm of 1,300 acres in Aberdeenshire, where he devoted his leisure hours to writing on agricultural subjects, his first production being a series of essays on planting contributed to the 'Edinburgh Weekly Magazine.' His principal works are, 'Encouragement of the National Fisheries'; 'An Inquiry into the Nature of Corn Laws'; 'Observations on Slavery,' and 'Recreations in Agriculture, Natural History, Arts, and Miscellaneous Literature' (1799-1802).

Anderson, John, a Scottish philosopher, founder of Anderson College, Glasgow: b. Roseneath, Dumbartonshire, 1726; d. 1796. He stud-

ied at the University of Glasgow, where he was afterward professor of Oriental languages, and later of natural philosophy. In addition to his usual class in physics he instituted one for artisans, which he continued to conduct to the end of his life. In 1786 appeared his 'Institutes of Physics,' which went through five editions in 10 years. He invented a gun whose recoil was stopped by air condensation; but having in vain endeavored to attract the attention of the British government to it, he went to Paris in 1791 and presented his model to the National Convention. It was hung up in their hall with this inscription over it, "The Gift of Science to Liberty." When the allies had drawn a military cordon around the frontiers of France Anderson suggested the expedient, which was adopted, of making small paper balloons, to which newspapers and manifestos were fastened and carried to Germany. Anderson by his will directed that his entire effects should be devoted to the establishment of an educational institution in Glasgow for the use of the unacademical classes. This college, opened with a single course of lectures, has now nearly 20 professors and lecturers; courses of instruction are given in physical and medical science and in chemistry; mathematics, Latin, Greek, Hebrew, French, music, etc., are also taught. As a school of medicine in particular it possesses a high reputation.

Anderson, John, Scotch physician and scientist: b. Edinburgh, 4 Oct. 1833; d. 1900. He obtained his medical degree at the University of Edinburgh, in 1862, and three years later was appointed superintendent of the Indian Museum at Calcutta, and was called to the chair of Comparative Anatomy in the Calcutta Medical College. In 1868–69 and again in 1874–75 he accompanied expeditions to western China as scientific officer. In 1881 the trustees of the Indian Museum commissioned him to investigate the marine zoölogy of the Mergui archipelago, the results of his researches being published in 'Fauna of Mergui and its Archipelago' (1889); and also in the *Journal* of the Linnæan Society (vols. XXI and XXII). In 1887 he retired from the service of the Indian Government. Among his writings, which are mainly reports to the government and scientific papers, the most noteworthy are: 'Mandalay to Momien' (1875); 'Anatomical and Zoölogical Researches' (1878); 'Two Expeditions to Western China' (1876); 'Herpetology of Arabia,' also containing a list of Egyptian reptiles and batrachians (1896); 'Handbook of the Archæological Collections in the Indian Museum;' 'Catalogue of the Mammalia in the Indian Museum,' etc.

Anderson, John Jacob, an American author and educator: b. New York, 30 Sept. 1821; d. 14 March 1906. Graduated at Normal School, College of City of New York, 1846. Teacher for 30 years in public schools of New York city; traveled over North and Central America, Europe, and Africa. He published a large number of text-books on history, chief of which are: 'Manual of General History' (1867); 'School History of the United States' (1868); 'Manual of Mediæval and Modern History'; 'History of France' (1877); 'Complete Course in History, Part 1' (1881).

Anderson, Larz, an American diplomat: b. Paris, France, 15 Aug. 1866; d. 1902. Graduated at Harvard, 1888; second secretary United States legation, London, 1891–3; first secretary, Rome, 1893–7; assistant adjutant general, United States Volunteers, during the Spanish-American war, 1898.

Anderson, Martin Brewer, an American educator: b. in Brunswick, Me., 12 Feb. 1815; d. 26 Feb. 1890; was graduated at Waterville College, now Colby University, in 1840; became professor of rhetoric and organized and taught the course in modern history at Waterville; and was president of the University of Rochester, N. Y., 1853 to 1888.

Anderson, Mary Antoinette, American actress: b. Sacramento, Cal., 28 July 1859. She was educated at the Ursuline Convent and the Academy of the Presentation Nuns in Louisville, and when 13 years of age began to study for the stage. She first appeared at Louisville on 27 Nov. 1875, in the character of Juliet. Her success was immediate, and during the following years she played with increasing popularity in the principal cities of the United States in various roles. In 1883 she appeared at the Lyceum Theatre in London and opened the Memorial Theatre at Stratford-on-Avon in the character of Rosalind in 'As You Like It,' and speedily became well known in England. At the age of 28 she married Antonio de Navarro and retired from the stage. In 1896 she published a volume entitled, 'A Few Memories.'

Anderson, Melville Best, American educator and author: b. Kalamazoo, Mich., 28 March 1851. He was educated at Cornell University (1870–74); the University of Göttingen (1875–76); and at the University of Paris (1876–77). Returning to the United States he occupied several professorships in some of the principal colleges, notably Butler University, Purdue University, the State University of Iowa, and in 1891 became professor of literature in Leland Stanford, Jr. University, which chair he has since occupied. He has translated and edited 'Paul and Virginia'; Hugo's 'William Shakespeare'; Boissier's 'Mme. de Sévigné'; Caro's 'George Sand'; Simon's 'Victor Cousin'; Sorel's 'Montesquieu'; Say's 'Turgot'; Rémusat's 'Thiers'; Joutel's 'Journal of La Salle's Last Voyage' (1896); Tonty's 'Relation' (1898); 'Nicholas de La Salle's Narrative' (1898); 'Cavalier de La Salle's Discovery of the Mississippi River' (1901), etc. He also edited 'Bacon's Essays, with Introduction and Notes' (1890); and wrote 'Representative Poets of the Nineteenth Century' (1896).

Anderson, Rasmus Bjorn, an American author: b. Albion, Wis., 12 Jan. 1846. Graduated at Luther College, Iowa, 1866, and University of Wisconsin, 1869. Professor of Scandinavian languages and literatures in University of Wisconsin, 1875–83; United States minister to Denmark, 1885–9. Author of 'America Not Discovered by Columbus' (1874); 'Norse' Mythology' (1875); 'Viking Tales of the North (1876); translator of Horn's 'History of the Literature of the Scandinavian North' (1884), of various stories by Björnson, 'The Younger Eddas' (1880), and G. Brandes' 'Eminent Authors of the 19th Century' (1886).

Anderson, Richard Henry, an American Confederate soldier: b. South Carolina, 7 Oct. 1821; d. Beaufort, S. C., 20 Feb. 1879. Graduated from West Point in 1842; served in Mexican war. In May 1861 he resigned from the United States army to join the Confederate service. He assisted in the bombardment of Fort Sumter and distinguished himself for gallantry throughout the war, especially at Fair Oaks, Gaines Mills, Frazier's Farm, Bull Run, and Gettysburg. He had the rank of major-general (1862) and lieutenant-general (1864), commanding the 4th corps of Lee's army in the last campaign.

Anderson, Robert, Scotch biographer and critic: b. Carnwath, Lanarkshire, 7 Jan. 1750; d. 20 Feb. 1830. In 1784 he became a resident and practitioner in Edinburgh, but soon after his marriage turned his attention to literary pursuits and finally ceased the practice of medicine altogether. He became editor of the 'Edinburgh Magazine,' wrote a 'Life of Dr. Johnson,' and published 'A Complete Edition of the Poets of Great Britain, with Prefaces Biographical and Critical' (14 vols. 1792–1807).

Anderson, Robert, an American soldier: b. near Louisville, Ky., 14 June 1805; d. in France, 26 Oct. 1871. Graduating at West Point 1825, he entered the artillery as second lieutenant. He was on Scott's staff in the Seminole war, 1837–8; in the Mexican war was badly wounded at Molino del Rey. Commissioned major in 1857, in 1860 he was given command of the troops in Charleston harbor, with headquarters at Fort Moultrie. Threatened with attack, the fort untenable, and the Buchanan administration making no reply to his appeals for its strengthening or for instructions, on 26 December he removed the garrison to Fort Sumter. An attempt of the government to provision it being assumed by the Confederates as a declaration of war, they invested it and compelled its surrender by a bombardment, 12–13 April 1861; its commander leaving with the honors of war. Appointed brigadier-general, he was assigned to the department of the Cumberland; but his health failing, he was relieved from active duty in October and retired in 1863. Brevetted major-general in 1865, in 1869 he went to Nice, France, for his health. He wrote works on tactics, and was instrumental in organizing the Soldiers' Home at Washington.

Anderson, Sir Robert, an Irish barrister and author: b. 29 May 1841. He was assistant commissioner of police in London, 1888–1901, and was knighted in the year last named. His published works include 'The Coming Prince'; 'A Doubter's Doubts about Science and Religion'; 'Human Destiny'; 'The Gospel and its Ministry'; 'Daniel in the Critics' Den'; 'The Silence of God' (1897); 'The Buddha of 'Christendom' (1899); 'The Bible and Modern Criticism' (1902).

Anderson, Rufus, American Congregational clergyman, and Secretary of the American Board of Foreign Missions: b. North Yarmouth, Me., 17 Aug. 1796; d. Boston, Mass., 30 May 1880. Having graduated at Bowdoin College in 1818, he studied theology at the Andover Theological Seminary, completing his course in 1822. In 1824 he became assistant secretary to the Board of Foreign Missions, serving as such till 1832, when he became full secretary. In this position he continued for 34 years, till 1866, when owing to his advanced age and failing health he retired. He inspected the missions in the Mediterranean in 1828–29 and again in 1843–44, the results of his tours of these years being chronicled in his 'Observations on the Peloponnesus and Greek Islands' (Boston, 1830). He also visited the Indian Missions in 1854–55, and the Sandwich Islands in 1863. From 1867 to 1869 he was lecturer on Foreign Missions in the Andover Theological Seminary. He with others founded the Mount Holyoke Female Seminary, at South Hadley, Mass., was for several years president of the board of trustees of Bradford Academy, Mass., and a member of the board of trustees of the Andover Theological Seminary. Besides his 'Observations' he also wrote: 'The Hawaiian Islands, Their Progress and Condition under Missionary Labors' (1864); 'A Heathen Nation Civilized'; 'A History of the Sandwich Islands' Missions' (1870); 'History of the Missions of the American Board of Commissioners for Foreign Missions to the Oriental Churches' (3 vols., 1872–4), etc.

Anderson, Ind., city and county-seat of Madison County; on the White River, 36 miles northeast of Indianapolis. It is the junction of four steam railroads, trunk lines, and is the centre of one of the most extensive systems of electric traction lines in the middle west. The power house is the largest in the State, generating the power which carries cars to every important city in northern and central Indiana.

Industries.—Anderson lies in the centre of a rich agricultural region and is also an important manufacturing centre. Here was established one of the first and largest tin plate mills, introducing that industry into the United States. Over 100 shops are engaged in industrial enterprises where nearly every commodity known to trade is made. Chief among these are tin plate, glass, wire fence, steel springs, nails, automobiles, carriages, shovels, files, wind pumps, steel tanks, shovel handles, carriage and buggy materials, tools and tool workers' supplies, encaustic tiles, etc. Natural gas was discovered in 1887, and while the flow has diminished to some extent it is still sufficient in supply for heating and small manufacturing purposes.

Banks, Public Works, Buildings, Etc.— The city has five banks, with a capitalization of $1,500,000, and deposits of $3,000,000; three daily papers; a city electric railway covering over 10 miles; 20 miles of brick paved streets; 50 miles of cement sidewalk; an excellent fire department, and owns and operates its own water and electric lighting plants. Among the prominent buildings are the Court House, erected in 1882 at a cost of $200,000, the Government building for postal service, a handsome public library, an Orphan's Home, and numerous hotels. There are many substantial school buildings, valued at $300,000, with a school enumeration of 6,500 children. Nearly all religious denominations are represented and well housed in the city.

History, Government, and Population.— The first settlement was in 1822, when, as the home of the Delaware Indians, it was known as Anderson's Town, the chief of the Delaware tribe being known as "Kik-tha-we-nund, or Ander-

son." Anderson's Town became a county-seat in 1827. The name was changed to Anderson by act of the Legislature in 1838, and in 1865 the city was incorporated. The city government is vested in a mayor and council, elected by the people. Pop. (1900) 20,178; (1905) 26,000.

JOHN L. FORKNER,
Mayor of Anderson.

Anderson, S. C., city and county-seat of Anderson County, on the Charleston & Western Carolina, and Blue Ridge railroads; 127 miles northwest of Columbia. The city was settled in 1827. It is in the centre of a large and fertile cotton-growing and agricultural region. It contains the city hall, court house and other large buildings, and numerous churches and schools. It has cotton-seed oil, eight cotton mills, lumber, and flour mills, and manufactures of fertilizers, clothing, machinery, and numerous small manufactories. The city is supplied by a private corporation with light and power from an electric plant located on the banks of the Seneca River, 10 miles distant. The same company supplies the water supply for the city. The municipal government is vested in a mayor and a council, elected every two years, under a charter of 1882. Pop. (1890) 3,018; (1900) 5,498; (1904) 8,500.

G. P. BROWNE,
Publisher 'Daily Mail.'

Andersonville, Ga., a village of Sumter County, 62 miles southwest of Macon, noted as the seat, during the Civil War, of a military prison of the Confederate States. This prison was established in November 1863, and consisted of an unsheltered enclosure containing at first 22 acres, an area subsequently increased to 27. It was commanded by Gen. W. S. Winder, but the superintendent was one Henry Wirz, a Swiss. It has been stated that Andersonville was selected as a suitable site because secure against Federal raiders and generally considered healthful; but that the laying waste of the fields of the South and the destruction of the means of transportation brought upon the Southern army and people great suffering, in which prisoners of war necessarily shared. It is true that rations were meagre for Confederate soldiers, to whose fare such prisoners were legally entitled. But evidence shows that the conditions which prevailed at Andersonville were due to mismanagement and cruelty; such evidence including ample Confederate testimony, as for example, that rendered by Dr. G. S. Hopkins and Surgeon H. E. Watkins, constituting a Confederate medical commission (1864), and that by Colonel Chandler of the Confederate war department in an inspection report (5 July 1864). Into the enclosure as many as 33,000 prisoners were at times crowded, for the most part completely without shelter, and supplied with insufficient and unsuitable food. Between February 1864 and April 1865 there were received at the prison 49,485 prisoners, of whom 26 per cent, or over 12,800, died there. In the autumn of 1864 the Confederate government removed many to Florence, S. C., and Millen, Ga., where they fared decidedly better. Wirz was convicted in 1865 by a military court under an indictment charging him with injuring the health and destroying the lives of prisoners, and was hanged 10 November. The prison burying-ground was made a national cemetery. Consult: Stevenson, R. R., 'The Southern Side; or Andersonville Prison' (1876); Chipman, 'The Horrors of Andersonville Rebel Prison' (1891); Schouler, 'History of the United States,' Vol. VI. (1899).

Andes, ăn'dēz, or, as called in Spanish South America, CORDILLERAS (ridges) DE LOS ANDES, or simply CORDILLERAS, a range of mountains extending along the whole of the west coast of South America, from Cape Horn to the Isthmus of Panama and the Caribbean Sea. Sometimes it is spoken of as a continuation of the Rocky Mountains in North America, but there seems to be no reason for this other than the continuity of the two divisions of America, and the fact that both ranges lie in the west of their respective continents. There is a sufficiently marked break between the ridges of the Isthmus of Panama and the range of the Andes of South America, and a still more distinct hiatus between the sierras of Central America and Mexico and the Rocky Mountains.

The south part of this huge chain begins to be continuous about lat. 52° S., and from this point to about lat. 42° S., a distance of nearly 1,100 miles, the range presses close to the Pacific Ocean. Its average height in this part is only about 3,000 feet, though several summits rise some thousands of feet higher, namely, Mount Melimoyu, Yanteles (the highest, above 8,000 feet), and the volcanoes of Corcobado and Minchinmadiva. The width of the chain in the extreme south is about 20 miles, further north it increases to 40 miles, and it attains a still greater width before reaching lat. 42° S. About this latitude the chain begins to recede from the coast, leaving wide plains on the west 1,000 or 1,500 feet above sea-level. North of lat. 35° S. a double range may be traced, and the whole system of mountains widens out to about 130 miles. At about lat. 21° S. the direction of the chain, which up to this point is north and slightly east, begins to change a little to the west, and around this elbow, as it were, is a knot of mountains, partly in Argentina and partly in Bolivia, consisting of chains running in various directions, some of which are unconnected with the chain of the Andes. This knot forms part of the watershed dividing the rivers of the La Plata from those of the Amazon basin. Among the peaks, up to 21° S. lat., are the active volcanoes of Antuco, Maypu, and Tupungato; but the culminating point of this portion, and so far as is known of the whole Andes, is Aconcagua, rising to the height of 23,028 feet, and distinctly visible from Valparaiso, 100 miles distant. The Chilean Andes, under the 35th parallel of south latitude, are about 150 miles from the Pacific; but this distance decreases to about 80 miles in the latitude of Valparaiso.

At lat. 21° S. the Andes range bifurcates, forming two chains of great elevation, the Andes of Bolivia and Peru, enclosing the lofty tableland or longitudinal valley of the Desaguadero and Lake Titicaca. Of these two chains the western or Peruvian has the peaks of Sahama, Parinacota, Gualateiri, and Pomarape, above 21,000 feet in height; and the eastern or Bolivian (Cordillera Real) those of Illimani and Sorata or Illampu (21,484 feet). The highest seems to be Gualateiri, the loftiest active volcano in the chain, 21,960 feet in height. Sahama, another active volcano, is 21,054 feet. These parallel cordilleras, the united breadth of

which nowhere exceeds 250 miles, are united at various points by enormous transverse groups or mountain knots, or else by single ranges crossing between them like dikes. The descent to the Pacific is exceedingly steep; the dip is also very rapid to the east, whence offsets diverge to the level plains. The table-land of the Desaguadero, thus enclosed, has itself an absolute altitude of 12,900 feet and an area of 150,000 square miles. A large eastern offset, the Sierra de Cochabamba, leaves the eastern cordillera under the 17th parallel, bounding the rich plain of Cochabamba north, and ending nearly under the 63d meridian of west longitude at Santa Cruz de la Sierra. The two main cordilleras once more unite in the group of Vilcañota, in lat. 15° S., and the united range then runs about 280 miles northwest to about lat. 10° S., where the Andes separate into three nearly parallel chains — the eastern, central, and western cordilleras, which enclose between them the Huallaga and Upper Marañon rivers; the western or coast cordillera running north as far as the group of Loja, near the southern extremity of Ecuador.

About lat. 6° S., opposite the Point Aguja, the Andes chain again takes a course north and slightly east, forming, as in Chile, a single mass or rocky plateau, 80 miles broad, covered with a double series of highly elevated summits enclosing longitudinal valleys, one of which, that of Cuenca, in the group of Assouan, is upward of 15,000 feet high, or nearly within the region of perpetual snow. North of this point the chain again divides, the western range comprising Mounts Chimborazo (21,240 feet), Iliniza, and Pichincha; while on the eastern range are the volcanoes Sangay, Tunguragua, Cotopaxi, Antisana (19,137 feet), and Mount Cayambe (19,535 feet). Shortly after entering New Granada, crossing the equator, the chain, in lat. 1° 5′ N., again meets in the knot or plateau of Los Pastos, on which is the volcano of Cumbal (16,620 feet); but a little north of the city of Pastos it once more bifurcates, enclosing the mountain plain of Almaguer, comprising the volcano of Purace (17,034 feet) on its eastern branch; and finally, somewhat north of the town of Popayan, the Andes separate into three distinct ridges — the Sierra di Choco, running north to the Isthmus of Panama; the Sierra di Quindiu, running east of the Cauca River; and the Sierra Suma Paz, extending east of the Magdalena to Lake Maracaibo and the city of Valencia in Venezuela. North of the fifth northern parallel the only summits within the snow line on these cordilleras belong to the eastern chain, which also is very precipitous on its eastern slope. On the Quindiu or central chain is the volcano of Tolima (18,325 feet), in lat. 4° 46′ N. The Choco or coast chain is of comparatively small elevation, its highest point not exceeding 9,000 feet. The total length of the Andes has been estimated at about 4,400 miles.

Passes, Roads, and Railways.— This gigantic mountain chain is traversed in its different parts by numerous roads or passes at heights almost equal to those of the extreme summits of the European ranges. Most of them are narrow, steep, and sometimes dangerous, passing through gorges, across yawning chasms, and up nearly perpendicular rocks; nor can they be attempted with success except by the active and well-practised native or the courageous and well-provided traveler. It is worthy of remark, likewise, that nearly all these roads cross the ridge transversely and direct, not, as is sometimes the case in the Alps, by a circuitous course through the longitudinal valleys. Subjoined is a list of most of the known mountain passes, with their position, connected localities, and highest elevation, commencing with those on the south.

Road over the Quindiu Pass	from Alausi to Cartago...	11,502

Besides the routes just mentioned, a great commercial road runs longitudinally along the Andes the whole distance from Truxillo, lat. 8° 5′ S., to Popayan, lat. 2° 25′ N., in the valley of the Cauca, not much less than 1,000 miles, and attaining at its highest point, the Paramo de Bolicha, an elevation of 11,500 feet. Two railways across the Andes have already been completed, both in the republic of Peru. The first in operation extends from the port of Mollendo, near the south of Peru, by Arequipa to Puno on Lake Titicaca, a distance of 217 miles. The eastern terminus of this railway is situated in a table-land 12,196 feet above the level of the sea. The first locomotive reached the shores of Lake Titicaca on 1 Jan. 1874. The other and more recent railway is from Lima to Oroya, a distance of 145 miles. The crest of the Andes is traversed by a short tunnel at an altitude of 15,645 feet above sea-level; the steep and irregular slope up to this point being ascended by a series of sharp curves, and the ravines spanned by bridges. A transandean railway from Buenos Ayres to Valparaiso is nearly completed.

Rivers and Lakes.— From the Andes rise two of the largest water systems of the world — the Amazon and its affluents, and the La Plata and its tributaries. Besides which, in the north, from its slopes flow the Magdalena to the Caribbean Sea, and some tributaries to the Orinoco, but no streams of importance flow from its western slopes. The number of lakes interspersed through this vast mountain system is not great, and in this respect it presents a striking contrast to the Swiss Alps. The

largest, and the only one worthy of notice, is that of Titicaca on the Bolivian plateau.

Geology, etc.— In considering the geology of the Andes, the first fact that strikes the observer is the vast development of volcanic force along the whole length of the chain, which is continued north through Guatemala and Mexico. These volcanic vents occur in three linear groups, the extreme southern extending from the 42d to the 33d parallel of south latitude; the next from the 27th to the 15th parallel, and the last from lat. 2° S. to about lat. 5° N. Mention has already been made of the principal volcanoes. Another striking circumstance in the geology of this range is that it consists almost entirely of sedimentary rocks, showing that its highest parts must at one time have been submerged. Granite comes so rarely to the surface in the northern parts of the chain, that, according to Humboldt, a person might travel for years in the Andes of Peru without meeting this species of rock; and he never saw any at a greater absolute elevation than 11,500 feet. Gneiss is sometimes found in connection with the granite; but mica-schist is by far the commonest of all the crystalline rocks. Quartz is likewise extremely abundant, generally mixed with mica, and rich in gold and specular iron. Vast tracts of red sandstone, with gypseous and saliferous marls, occur in Peru. Porphyry and greenstone abound all over the range at every elevation, both on the slopes and extreme ridges; and trachyte is almost as abundant as porphyry, both in Peru and Chile, great masses of it, from 14,000 to 18,000 feet thick, being visible on Chimborazo and Pichincha. As respects volcanic products, the western face of the Andes presents immense quantities of lava, tufa, and obsidian, none of which are found on the eastern side; this applies especially to that part of the chain lying between Chile and the equator. Fossil remains are by no means common; but in the limestone strata of the coast toward the northern extremity of the range Humboldt found many marine shells of the Silurian period, about 30 miles from the coast; and Pentland observed others of the same era at a height of 17,500 feet on Mount Antakawa in Bolivia, as well as in several other parts.

Earthquakes.— Many of the volcanoes, as before observed, are in a state of either constant or occasional action; it cannot, therefore, be matter of surprise that there should be frequent and violent earthquakes. All the districts of the Andes system, but Chile especially, have suffered more severely from these oscillations than any other part of the world; and among the towns either destroyed or greatly injured by these visitations may be mentioned Bogotá, Quito, Riobamba, Lima, Callao, Valparaiso, and Concepcion. In 1819 Copiapo was entirely overturned, not a house being left standing. Concepcion was twice destroyed — in 1730 and 1751; and in November 1822 an earthquake was felt on the same day at this town, in lat. 37° S., and at Lima in lat 12° N., more than 1,700 miles distant; it was on this occasion that Valparaiso, Melipella, and Quillota were all but completely annihilated. This earthquake, too, had the remarkable effect of upheaving the land on the coast, upward of 100 miles in extent, to the height of three or four feet, and elevating a portion of the shore above high-water mark. These shocks continued at brief intervals till the autumn of 1823; and since that time the volcanoes of Maypú, until then for many years quiescent, have had frequent eruptions. In August 1868 the towns of Arequipa, Iquique, Tacna, and many other smaller towns in Peru and Ecuador, were destroyed. Earthquakes, slight or more serious, are of yearly occurrence, and faint oscillations of the soil are regarded with scarcely more attention than a hail-storm in the temperate zone.

Mineral Productions.— The Andes are extremely rich in the precious metals. In Chile, Bolivia, Peru, and Colombia gold is obtained. Silver occurs in Chile in the provinces of Coquimbo and Atacama, and the mines of these districts are remarkable for the richness of their ores. The Peruvian Andes have numerous silver mines scattered over their whole extent from the province of Caxamarca south to the confines of Chile; but incomparably the richest are the mines of Cerro de Pasco, which have been worked upward of two centuries. The mines of Chota likewise, which are situated on Mount Hualgayoc, are productive. The ore, which is richer even than that of Pasco, lies either on or very near the surface. Close to the Pacific, at Huantajaya, in the district of Arica, are several mines celebrated for the quantity of virgin silver found therein, sometimes in masses of great weight. The most famous mines are those of the Cerro de Potosi, in Bolivia, lat. 19° 36′ S., which is perforated in all directions by thousands of openings, some of which are within 100 feet of the summit (16,000 feet). Quicksilver is found in several parts of the Andes, but in combination with sulphur, forming the red sulphuret of mercury commonly known as cinnabar. Copper is found both in the east and west cordilleras of Peru; but the eastern chain is too far from the coast to admit of mines being profitably worked. The copper mines of Chile are the most valuable. They are situated chiefly in the desert of Atacama. Tin also, wrought in Chile, forms an article of export; but lead and iron, though plentiful, are not worked. Considerable platinum is obtained from the state of Choco in Colombia.

Climate and Meteorology.— On the western side of the range little or no rain falls, except at the southern extremity; and scanty vegetation appears only in spots, or in small valleys, watered by streams from the mountains; while on the opposite slope excessive heat and moisture combine to give the range a thick covering of tangled forest trees and dense brushwood. Currents of cold west and northwest winds blow nearly all the year from the ice-topped cordilleras on the plateau beneath, daily accompanied during four months by thunder, lightning, and snow storms. Currents of warm air are also occasionally found on the crest of the Andes; they usually occur two hours after sunset, being both local and narrow, like the hot blasts in the Alps, not exceeding a few yards in width. They run parallel to each other, and so closely that five or six of them may be passed in a few hours. They blow chiefly from south-southwest to north-northeast and are especially frequent in August and September. Notwithstanding the great number of snow-clad summits, glaciers are of rare occurrence in the

Andes, being found only, and then of but small extent, in the narrow ravines which furrow the sides of some of its giant summits.

Vegetation.— In the low torrid plains that flank the bases of the Andes reign the banana, cycas, plaintain, cassava, cacao, the cotton tree, indigo and coffee plant, and sugar-cane, all of which are extensively and profitably grown below the altitude of 4,000 feet. Maize is likewise plentiful, and may be said to form the bread of the Peruvians; it is of three different kinds, and, according to Humboldt, is cultivated 7,000 feet above the sea. Within the same limits also are found, either wild or cultivated, the pineapple, pomegranate, shaddock, orange, lime, lemon, peach, apricot, together with olives, aji or pepper plants, tomatoes, sweet potatoes, gum copal, copaiba balsam, dragon's blood, sarsaparilla, and vanilla. To these groups succeed, in the humid and shaded clefts on the slopes of the cordilleras, the tree-ferns, and cinchona or cascarilla, whence we derive the febrifuge bark and quinine. Between the heights of 6,000 and 9,000 feet is the climate best suited for the European cereals. To these may be added the quinoa (*Chenopodium quinoa*), a most useful production for domestic uses. In this region also, and a little above it, grow the potato, indigenous to Chile and thence introduced into Europe, and various tuberose congeners, all extensively used as food; and here likewise grow the chickpea, broad bean, cabbage, and other European vegetables. Within the cereal limits are found the oak, elm, ash, and beech, which never descend lower than 5,500 feet, and seldom rise higher than 9,200 feet above the sea. Above this level the larger forest trees, except the pine, begin to disappear.

Zoology.— The fauna of the Andes is still very imperfectly known. Among the carnivorous animals the principal are the jaguar, puma, ounce, ocelot, and wild-cat. There are also bears, tapirs, raccoons, wild hogs, foxes, and otters, with both red and roe deer. The characteristic animals of the Andes, however, are the llama and its different congeners — the guanaco, vicuña, and paco or alpaca. They are the chief beasts of burden on the Andes. The forests of the warmer regions abound with members of the monkey tribe, etc. Many varieties of serpents are found. Bats are numerous and of large size, the vampire bat being one of the most remarkable. The condor soars over the highest summits, making its nest among the highest and least accessible rocks; other birds of prey are also numerous. Curassows, wild turkeys, parrots, and parrakeets are common in the woods, and there are also a great many varieties of smaller birds.

MARRION WILCOX,
Authority on Latin-America.

An'des and the Amazon, The, a volume of travels by James Orton (1870, enlarged ed. 1876). Under the auspices of the Smithsonian Institution, the author, who for many years was professor of natural history at Vassar College, led an exploring expedition to the equatorial Andes and the river Amazon. Its experiences are set forth in this work.

Andesine, ăn'dēz-ĭn, a triclinic feldspar, intermediate in composition between albite and anorthite. Albite and anorthite are isomorphous, and andesine includes those mixtures of the two in which the ratio of albite to andesine ranges from 1:1 to 3:2. Andesine may be described as an anhydrous silicate of sodium, aluminum, and calcium. Its hardness is from 5 to 6, and its specific gravity about 2.68. In color it is white, gray, greenish, yellowish, or pink. It was first found in the Andes (whence the name), but has since been observed in Alsace, in Iceland, and in other localities. In the United States it occurs at Sanford, Me.

Andesite, ăn'dēz-īt, a common volcanic rock, consisting of a triclinic feldspar (such as andesine) mixed with hornblende or augite and sometimes also with quartz. It varies in color from green to gray and occasionally has a purplish cast. It is difficult to define andesite accurately because basalt, andesite, and trachyte are similar in composition, and intermediate varieties exist, which, with the typical rocks of the three classes, form an almost continuous series. Andesite is more fusible than trachyte, but less fusible than basalt.

Andigan, än'dĭ-jän', a city of the Russian khanate of Khokandin, central Asia. It is the centre of an immense cotton-raising district, whence Russia received three fourths of all the cotton used in the empire. In 1902 the city was totally destroyed by an earthquake which killed over 5,000 of the 47,000 inhabitants.

Andira, ăn-dī'rȧ, a genus of leguminous typical American trees, with fleshy plum-like fruits. The wood is well fitted for building. The bark of *A. inermis,* or cabbage-tree, is narcotic, and is used as an anthelminthic under the name of worm bark or cabbage bark. The powdered bark of *A. araroba* is employed as a remedy in certain skin diseases, as herpes.

Andocides, ăn'dŏs'ĭ-dēz, an Athenian orator: b. 467 B.C.; d. about 393 B.C. Active in public affairs, he was four times exiled; the first time along with Alcibiades, for profaning the Eleusinian mysteries. Three of his orations are extant.

Andorra, ȧn-dŏr'rȧ, a small republic in the Pyrenees between Ariège, a department of France, and Lérida, a province of Spain. It is only partially independent, being under the suzerainty of both France and Spain. The town covers an area of 175 square miles and the inhabitants are devoted chiefly to cattle-raising and iron and lead mining. The republic and its history have attracted much attention from students of governmental institutions. Pop. 6,000. See Tucker, 'The Valley of Andorra' (1882); Deverell, 'History of the Republic of Andorra' (1885); Spender, 'Through the High Alps' (1898).

An'dover, an English market town in Hampshire, 12 miles west of Winchester. Its large parish church was built about 1850 on the site of a Norman predecessor. The Massachusetts Andover was named in honor of the Hampshire town. Pop. about 6,000.

An'dover, Mass., a town in Essex County, on the Merrimac River and the Boston & M. R.R.; 23 miles north of Boston. It is widely known as the seat of the Andover Theological Seminary (q.v.), the Phillips Academy for boys, and the Abbot Academy for girls, and has manufactories of flax, shoes, and woolen goods, two national banks, Memorial Hall, and school libra-

ries, a free public library of over 12,000 volumes, and a property valuation of over $4,000,000. Harriet Beecher Stowe lived here many years, and it was long the home of Elizabeth Stuart Phelps Ward. It was first settled in 1646. Pop. (1900) 6,813.

An'dover Theolog'ical Seminary, Andover, Mass., one of the oldest and most famous theological schools in the United States. It was founded in 1807, at a period when there was little provision for special education in theology, the Greek or Hebrew languages, Biblical criticism, etc.; and it was usual for ministerial candidates to study for a time under the private tuition of some noted divine. These private divinity schools were often very effective intellectually and practically, but could not supply the minute and accurate scholarship of regular institutions with longer set terms, the need of which was now sharply felt. At this time also, not only was New England divided into strenuous Calvinists and semi-Calvinists or outright Arminians, but the former were themselves divided into Calvinists proper and Hopkinsians, a more extreme type. Under a common alarm at the inroads of religious liberalism, however, the former drew together and united in upholding a general theological seminary. This was founded by Samuel Abbot, a Boston merchant, who associated with him Phœbe Phillips, widow of the founder of Phillips Academy, and her son John; and the three drew up a constitution for the seminary, submitted it to the General Assembly June 1807, and committed it to the board of trustees 31 Aug. 1807. The articles were rigidly drawn to prevent the teaching of anything but the especial form of Calvinism held by the founders, the endowment to be forfeited if these restrictions were disregarded. But no such provision could be enforced in an age of free thought and consequent flux of belief without shutting up the seminary. The trustees have had twice to choose between relaxing the iron-bound rules of the deed and closing the doors. By the irony of fate the defenders against assaults for heresy in the one generation were the chief prosecutors of it in the next. The seminary makes no charge for tuition or room rent, the endowment fund ($850,000 in 1901) providing for all; and though under Congregational control it is free to all Protestants who can present a college diploma. The latter requirement can be waived by the trustees. The library contains over 30,000 volumes. In 1900 there were six professors besides five lecturers and tutors. President, Geo. Foot Moore, D.D. (For its foundation and history from a rigidly orthodox standpoint see Leonard Woods' 'History of Andover,' Boston, 1884.)

An'drādīte (named for the Portuguese mineralogist, d'Andrada), the common or black garnet. See GARNET.

Andral, än'drȧl', **Gabriel,** a distinguished French physician and pathologist: b. in Paris, 6 Nov. 1797; d. 13 Feb. 1876. In 1827 he was called to the chair of hygiene, in 1830 to that of pathology in the University of Paris. Andral may be said to have been the first to apply an analytical and inductive method to pathology. His 'Medical Clinic' (1824) established his reputation, and his 'Summary of Pathological Anatomy' (1829) was equally successful. Other works of importance are his 'Essay on Pathological Hæmatology' (1843); 'Course in Pathology — Interne'; and 'Investigations into the Modification of the Relative Proportions of Hæmatic (Blood) Principles.'

Andrassy, än'drä-shĭ, **Julius, Count,** Hungarian statesman: b. Zempben, 8 March 1823; d. 18 Feb. 1900. He took part in the revolution of 1848 and was condemned to death, but escaped and went into exile. Appointed premier when self-government was restored to Hungary in 1867, he became imperial minister for foreign affairs in 1871; drew up the famous Andrassy note to the Porte in 1876; was a conspicuous member of the Congress of Berlin in 1878; negotiated the German-Austrian alliance with Bismarck in 1879; retiring the same year from public life. The Andrassy "Note" was a declaration relating to the disturbed condition of Bosnia and Herzegovina, formulated by the governments of Austria, Russia, and Germany, with the approval of England and France. It commanded the establishment of religious liberty, the application of local revenues to local purposes, and other reforms, and was formally presented to the Porte, 31 Jan. 1876.

André, än'dra, or ăn'drĭ, **John,** a British soldier: b. London, of Swiss-French parentage, 1751; executed at Tappan, N. Y., 2 Oct. 1780. His fate is peculiar; failure has given him a monument in Westminster Abbey from his own side, and undying romantic pity from the other, where success would have loaded him with infamy from one, and made the other glad to forget him. He entered the English army at 20, and was sent to Canada in 1774; November 1775 he was taken prisoner at St. John's by Montgomery's expedition and sent to Lancaster, Pa. Exchanged in December 1776, he was made captain in 1777, aide to Gen. Charles Grey, major in 1778, and in 1779 aide to Clinton and adjutant-general of the forces in America. He owed this rapid advancement, as he has owed his enshrinement by posterity, to his extraordinary and somewhat feminine charm of person and manner, which won the hearts not only of his chiefs and associates, but of the very officers who put him to death. He was full of wit and vivacity, a most entertaining companion, a good amateur musician and artist, and a fluent, pleasing writer, which, more than all else, made him Clinton's adjutant and secretary. He was also a fair society poet, known in London literary circles; and his casual skits in verse, 'The Cow Chase,' 'Yankee Doodle's Expedition to Rhode Island,' 'The Affair Between Generals Howe and Gadsden,' etc., were great favorites in the English army. During that army's winter in Philadelphia, 1777–8, André was the promoter of and a chief actor in all the festal occasions and social events, including the 'Mischianza,' a pageant in honor of Howe on his departure. In 1780 it fell to his official duty to conduct Clinton's negotiations with Benedict Arnold (q.v.) for the betrayal of West Point, the key of the Hudson, whose command Arnold had solicited in order to betray it, with its magazines and the entire stock of powder of the American army. Both sides were wary and suspicious of each other, and Clinton uncertain of his correspondent's identity or whether the affair might not be

a trap. After various abortive attempts at a secret interview, André, on 19 September, went as "John Anderson" up the Hudson in the sloop-of-war Vulture, nearly to the American lines above Fort Montgomery. The plan was to meet under a flag of truce, on pretense of arranging as to the confiscated property of the loyalist Col. Beverly Robinson, whose house was Arnold's headquarters; but this, too, failed, and finally on the night of 21 September Arnold induced a loyalist farmer, Joshua Smith, to carry a packet from Robinson to "Anderson" on the Vulture. André returned with Smith, was met on the shore by Arnold, and after a private conference the two went to Smith's house, where they spent the night and part of the next day arranging the betrayal, which was fixed for the day of Washington's expected return. Arnold gave him six papers containing drawings of the West Point defenses and full information concerning them, and passes to return to New York either by land or water. He also sent Smith as escort, charged not to leave André till he had reached the English lines in safety. But in the morning the American batteries had fired on the Vulture and driven her so far down stream that the boatmen would not carry him to her. André, therefore, disguising himself as a civilian, set out on horseback, carrying the papers in his boots. Smith, despite Arnold's injunction, left André on the way, probably in fear for himself. About 9 A.M. of the 23d, near Tarrytown, and almost in sight of the British lines, he was stopped by three patriot militiamen, John Paulding, David Williams, and Isaac Van Wart. Supposing them to be Tory "cowboys," he told them he was an English officer, and offered them money. Finding that they were not loyalists, he offered more and his horse, showing also Arnold's pass. Their suspicions thoroughly aroused, they searched him, found the papers, and carried him to one Lieut-Col. Jamison, who, not suspecting treachery on Arnold's part, notified him of the capture and proposed to hand the prisoner over to him. The gleam of hope was delusive, and André was finally sent to Washington, while Arnold fled to the Vulture and saved his own life. By military law André was, of course, subject to immediate hanging; but in consideration of his rank, Washington on 29 September convened a military court of six major-generals and eight brigadier-generals, with Gen. Nathanael Greene as president, who unanimously convicted him of being a spy and sentenced him to death on 2 October. Clinton, of course, did his best to save André, protesting that he was not a spy because he was under a flag of truce (which was false), and that his movements were in obedience to the directions of Arnold, an American commander,— a grimly humorous defense under the circumstances; but Washington replied with firm courtesy that the circumstances justified no exception to the rules of war. André died like a man, and need not be grudged our pity; but he was treated with a generous humanity curiously in contrast with the treatment accorded to Nathan Hale.

A monument to André was placed in Westminster and in 1821 his remains were taken up and reburied near it. See Sparks, 'Life of André' in 'American Biographies'; Sargent, 'Life of André' (1861); Lossing, 'Two Spies,' 1886. Lord Mahon in his 'History of England' assumes Clinton's case for André as good both in law and in equity. In 1858 Charles J. Biddle, a Philadelphia editor and ex-soldier, reviewed Mahon's opinions before the Pennsylvania Historical Society. See its 'Memoirs,' Vol. VI. For documents see H. W. Smith's 'Andréana' (1865); Dawson's 'Collection' (1866).

André, än'dra, **Louis Joseph Nicolas,** a French military officer: b. in Nuits, Burgundy, 29 March 1838. He was graduated at the Polytechnic School, and in 1865 became captain, serving in that capacity throughout the Franco-Prussian war of 1870–1. He was made general of brigade in 1893 and placed in charge of the Polytechnic School. On 29 May 1900 he was appointed minister of war by President Loubet, succeeding General the Marquis de Gallifet, who held the office during the exciting period of the Dreyfus revision.

André, än'dra, **St., Jacques d'Albon,** Marquis of Fronsac, generally known as Maréchal de St. André, a French nobleman, made gentleman of the bedchamber by Henry II. In 1550 he was deputed to bear the collar of his order to Henry VIII. of England, by whom he was invested with that of the Garter. On his return he was appointed to the command of the army in Champagne, where he greatly distinguished himself till taken prisoner at the battle of St. Quentin. On the death of Henry II. he was chosen one of the regency. Killed at the battle of Dreux in 1562. The Huguenots called St. André «The Harquebusier of the West."

Andreä, än'dra, **Jakob**, a German Protestant theologian: b. in Waiblingen 25 March 1528; d. in Tübingen 7 Jan. 1590; became professor of theology and chancellor of the University of Tübingen in 1562, and was the author of over 150 works, nearly all of a polemical character, besides being the chief author of the 'Formula Concordiæ.'

Andreä, an'dra, **Johann Valentin,** a German theologian: b. Herrenberg in 1586, near Tübingen; d. Stuttgart, 1654. He studied at Tübingen, became a Protestant pastor, and was chaplain to the court at Stuttgart. Eminently practical in mind, he was grieved to see the principles of Christianity made the subject of mere empty disputations, and accordingly devoted his life to the correction of this tendency of his age. His writings are remarkable for the wit and humor as well as for the acuteness and moral power which they display. He was long regarded as the founder or restorer of the order of the Rosicrucians, a view based on his quaint but misunderstood 'Chemical Jubilee of Christian Rozenkreuz' (1616). But his intention was certainly not to originate or promote a secret society of mystics, but to ridicule the follies of the age, including the theosophic Rosicrucians. He wrote mainly in Latin, but also in the Suabian dialect. Among the best of his works are his 'Menippus, or a Hundred Satyric Dialogues' (1617), and his 'Spiritual (Clerical) Relaxation' (1619).

An'drea del Sarto. See SARTO.

Andreasberg, än-drā'äs-bĕrg, **Saint,** a Prussian mining town in the province of Hanover, 57 miles southeast of the town of Hanover, on a site, 1,800 feet above sea-level, a little to the

southwest of the Brocken. The minerals obtained in the mines of the district are silver, copper, lead, arsenic, etc. The Samson shaft, 2,950 feet deep, is the deepest mine in the Harz Mountains. Pop. 4,000.

Andree, än'dra, **Salomon Auguste,** a Swedish aëronaut: b. in Grenna, 18 Oct. 1854; date of death unknown. He was educated in Stockholm. In 1882 he took part in a Swedish meteorological expedition to Spitzbergen. In 1884 he was appointed chief engineer to the patent office, and from 1886 to 1889 he occupied a professor's chair at Stockholm. In 1892 he received from the Swedish Academy of Sciences a subvention for the purpose of undertaking scientific aërial navigation. From that time he devoted himself to aërial navigation, making his first ascent at Stockholm in the summer of 1893. In 1895 he presented to the Academy of Sciences a well-matured project for exploring the regions of the North Pole with the aid of a balloon at an estimated cost of about $40,000. A national subscription was opened, which was completed in a few days, the king of Sweden contributing the sum of $8,280. With two companions, Dr. S. T. Strindberg and Herr Fraenckell, Andree started from Dane's Island, Spitzbergen, 11 July 1897. His balloon was 67¼ feet in diameter, with a capacity of 170,000 cubic feet. Its speed was estimated at from 12 to 15 miles an hour, at which rate the Pole should have been reached in six days provided a favorable and constant wind had been blowing. Two days after his departure a message was received from Dr. Andree by carrier pigeon, which stated that at noon, 13 July, they were in lat. 82.2° and lon. 15.5° E., and making good progress to the east, 10° southerly. Several expeditions sent in search of Andree have returned without obtaining any further intelligence of the explorer.

Andreini, än'dra-ē'nẹ, **Giovanni Battista,** an Italian comedian and poet: b. in Florence, 1578; d. in Paris about 1650. From his sacred drama, 'Adam' (1613), Milton is by some supposed to have derived the idea of 'Paradise Lost.'

An'dreolite, än'drē-ō'līt (from Andreasberg, in the Harz Mountains), a mineral better known as harmotome (q.v.). The name andreolite should be retained for it according to the law of priority; but mineralogists have preferred to adopt the name harmotome, as given by Haüy, although no good reason can be assigned for so doing.

Andreossy, än'dra'ọ'se', **Antoine François, Count,** a French general and statesman: b. Castelnaudary in Languedoc, 6 March 1761; d. at Montauban, 10 Sept. 1828. He entered the artillery in 1781, joined the revolutionists, served under Bonaparte in Italy and Egypt, and took part in the revolution of the 18th Brumaire. He was ambassador at London, at Vienna, and at Constantinople, from which latter post he was recalled at the restoration. He was raised to the peerage by Napoleon after his return from Elba. After Waterloo he advocated the recall of the Bourbons, but, as deputy, generally took part with the Opposition. He was elected to the Academy in 1826. He was a man of eminent scientific attainments, one of his earliest works being the 'Histoire Générale du Canal du Midi (1800). Besides his scientific works he wrote several military "Memoirs."

An'drew, a Neapolitan king, assassinated with the connivance of his queen in 1345.

An'drew, James Osgood, an American Methodist bishop: b. in Wilkes County, Ga., 3 May 1794; d. in Mobile, 1 March 1871. He was an itinerant preacher in South Carolina from 1816 till consecrated bishop, 1832. His social relations were the immediate cause of the division of the Methodist Episcopal Church into "North" and "South." His second wife whom he married in 1844 was a slave holder; and the General Conference of that year resolved that he should "desist from the exercise of his office" on the ground that the fact of his wife's owning slaves "would greatly embarrass if not in some places entirely prevent" the exercise of this office. The Southern delegates protesting against this action, the difficulty was settled only by dividing the churches and property into the Northern and Southern jurisdiction. Bishop Andrew adhered to the South, retiring from active work in 1868.

An'drew, John Albion, an American statesman, the "War Governor" of Massachusetts: b. Windham, Me., 31 May 1818; d. Boston, 30 Oct. 1867. He was graduated from Bowdoin College in 1837, and practised law in Boston 1840–61. He was an earnest anti-slavery advocate and defended the fugitive slaves Shadrach, Burns, and Sims. Elected to the State legislature in 1858, was a delegate to the Chicago Convention in 1860, and being nominated governor was elected by an immense majority. He forecast the war, announced in his message the intention to put the State militia on a war footing, and privately invited co-operation from other governors. On Lincoln's first call for troops, 15 April 1861, he sent them so promptly that on 19 April the 6th Massachusetts shed the first blood of the war in passing through Baltimore, and within a week he had dispatched to the front five regiments of infantry, a battalion of riflemen, and a battery of artillery. In 1862 he urged the national abolition of slavery and the enrollment of colored troops, and in 1863 sent out the first colored regiment, 154th Massachusetts; yet he repeatedly interfered to prevent harrying Southern sympathizers by arbitrary arrests, and after the war was foremost in urging conciliation and abstinence from vindictive or humiliating measures. He was re-elected regularly till 1866, when he refused further honors from pecuniary grounds and impaired health, continuing his law practice till death. He was a man of great personal charm and oratorical force, intensely sympathetic and humane, and of simple and frank nature. In religion he was a moderate Unitarian, believing in Christ's supernatural character, and was president of the first Unitarian National Convention in 1865.

An'drew, Saint, one of the twelve Apostles, and the brother of Peter. There are four important references to him in the gospels. John i. 40, the only account of his introduction to Jesus, in which as a disciple of John the Baptist he follows Jesus on John's word and brings his brother Peter to him; John vi. 8, where he calls attention to the boy with the barley loaves, when the miracle of the loaves

and fishes occurs; John xii. 22, where Philip, asked by the Greeks if they may see Jesus, consults Andrew before laying the request before Jesus; and Mark xiii. 3, where he is one of the four who privately asked Jesus the meaning of his utterance about the ruin of the temple. The other two synoptics do not allude to him. John i. 44 says he was from Bethsaida in Galilee. Tradition early gave him a conspicuous place among the Twelve, and very important "acts of the Apostle Andrew" were in circulation as early as the middle of the second century, but have survived only in later recasting. There were also acts of Matthew and Andrew, and of Peter and Andrew, and a "Martyrdom of Andrew." A gospel of Andrew is mentioned later, but not otherwise known. A tradition of unknown date and no value accredits him with preaching in north Greece and Epirus and in Scythia, and being martyred on a cross shaped like an X at about 70 A.D.

Andrew I., a king of Hungary, 1046–1061; compelled his subjects to embrace Christianity, exiled his brother Béla, and died in battle.

Andrew II., king of Hungary, 1205–1235, who fought in the crusades, and displayed great valor; granted the Golden Voull, styled the Hungarian Magna Charta.

Andrew III., king of Hungary, 1290–1301. He was opposed in his claims to the throne, and involved in a civil war during his reign; he died in 1301.

An'drew, Saint, Cross of, is a white saltire on a blue ground, to represent the X-shaped cross on which the patron saint of Scotland suffered martyrdom, from an early date adopted as the national banner of Scotland. It is combined with the crosses of St. George and St. Patrick in the Union Jack. The Scottish Order of the Thistle is sometimes known as the Order of St. Andrew.

An'drew, Saint, The Russian Order of, the most important of Russian orders, founded by Peter the Great in 1698. It has but one class and is confined to members of the imperial family, princes, and persons of the rank of general who already hold two other important orders. The badge of the order displays on the obverse the double-headed eagle, crowned, on which is a St. Andrew's cross enameled in blue, with a figure of the saint and bearing in the four corners the letters S. A. P. R. (*Sanctus Andreas Patronus Russiæ*).

An'drewes, Lancelot, an eminent bishop of the English Church: b. near Barking, Essex, 1555; d. London, 25 Sept. 1626. Having taken orders he was appointed to the parsonage of Alton, afterward to the vicarage of St. Giles, Cripplegate, and in 1589 was made a prebend and canon of St. Paul's, and master of Pembroke Hall. Queen Elizabeth, esteeming him highly, appointed him one of her chaplains in ordinary, besides bestowing other preferment upon him; and he was in no less favor with James I. In 1605 he became bishop of Chichester, in 1609 was translated to Ely and appointed one of the king's privy councilors, and in 1618 was translated to Winchester. He was one of the greatest preachers of his time, and was one of those engaged in preparing the authorized version of the Scriptures. He left sermons, lectures, and other writings, a manual of private devotions compiled by him in Greek and Latin being well known through several English translations.

An'drews, Charles Bartlett, an American jurist: b. Sunderland, Mass., 4 Nov. 1834; d. Litchfield, Conn., 12 Sept. 1902. He was graduated from Amherst College; member Connecticut Senate 1868–9; of the House 1878; governor of Connecticut 1879–81; judge of the supreme court 1882–9, and chief justice 1889–1901. He presided over the Connecticut constitutional convention of 1902.

An'drews, Charles McLean, an American historical and descriptive writer: b. in Wethersfield, Conn., 22 Feb. 1863; became professor of history at Bryn Mawr College; author of 'Historical Development of Modern Europe;' 'River Towns of Connecticut;' 'The Old English Manor,' etc.

An'drews, Christopher Columbus, an American diplomat and writer: b. in Hillsboro, N. H., 27 Oct. 1829; was brevetted major-general in the Civil War; United States minister to Sweden from 1869 to 1877, and consul-general to Brazil from 1882–1885. Among his many works are 'Minnesota and Dakota' (1857); 'Practical Treatise on the Revenue Laws of the United States' (1858); 'History of the Campaign of Mobile' (1867), and 'Brazil, Its Condition and Prospects' (1887).

An'drews, Edward Gayer, an American clergyman: b. New Hartford, N. Y., 7 Aug. 1825. Graduated from Wesleyan University, Conn. 1847; entered the Methodist ministry 1848; principal of Casenovia Seminary, 1854–64; pastor in Stamford, Conn., and Brooklyn, N. Y., 1864–72; and elected bishop 24 May 1872. He visited missions in Europe and India 1876–7; Mexico 1881; Japan and China 1889–90; and was delegate to English and Irish Methodist Churches 1894.

An'drews, Elisha Benjamin, an American college president: b. Hinsdale, N. H., 10 Jan. 1844. Served in Connecticut regiments through the Civil War, rising to the rank of 2nd lieutenant; graduated at Brown University 1870, and Newton Theological Institution 1874. Teacher and pastor, 1874–82, professor of history and political economy at Brown 1882–8; of political economy and finance at Cornell 1888–9. In the year last named he was elected president of Brown University and under his administration that institution greatly increased its efficiency. In 1897 he resigned the presidency on account of criticism of his views on the silver question, but complied with the request of his trustees to withdraw his resignation. He was elected superintendent of schools in Chicago 1898, and in July 1900, chancellor of the University of Nebraska. He has written: 'Institutes of General History' (1887); 'Institutes of Economics' (1892); 'An Honest Dollar' (1894); 'Wealth and Moral Law' (1894); 'History of the Last Quarter Century in the United States' (1896). Colby University conferred on him the degree of D.D., and the University of Nebraska that of LL.D.

An'drews, Ethan Allen, an American scholar: b. New Britain, Conn., 7 April 1787; d. there 4 March 1858. Graduated at Yale in

1810, studied law and practised for some years. Then taught ancient languages in University of North Carolina, the New Haven gymnasium, 1822–9; established New Haven Young Ladies' Institute, 1830; succeeded Jacob Abbott as head of a young ladies' school in Boston 1833–9. Returning to New Britain he devoted himself to the publication of a series of Latin text-books, which soon became widely used throughout the United States. The most important of these were 'Andrews' and Stoddard's Latin Grammar'; and 'Latin-English Lexicon' (1850), an abridged translation, with alterations and additions, of Freund's 'Wörterbuch der Lateinischen Sprache.'

Andrews, George Pierce, American jurist: b. North Bridgeton, Maine, 29 Sept. 1835; d. New York 24 May 1902. He was educated at Yale, studied law and was admitted to the bar in 1861. He was United States district attorney for six years, assistant and corporation counsel, New York, 1872–84, and associate justice of the New York supreme court, 1884–1901. He was esteemed a high authority on municipal and corporation law and his opinions in tax cases were especially valued. A very notable event in his career was his conviction of Capt. Nathaniel Gordon in 1860 for slave trading. Gordon was captured with a crew of nearly 900 negroes, was twice tried for piracy and finally convicted as a result of the convincing argument of Andrews. It is generally conceded that the conviction and execution of Gordon ended the slave trade in the United States. It had existed for more than 300 years, and for 42 years after Congress had made it piracy, punishable with death. Thousands of negroes had suffered tortures on the long voyages between African and American ports, and thousands more had died and been cast overboard, but not a person engaged in the nefarious traffic had been punished in this country until Mr. Andrews obtained the conviction and execution of Gordon. Prior to that event 130 vessels had been engaged in the slave trade, and New York was their headquarters. See UNITED STATES — SLAVERY IN THE.

An'drews, Jane, an American juvenile story-writer: b. in Massachusetts in 1833; d. 1887. Among her stories for children which have enjoyed great popularity are 'Seven Little Sisters Who Live on the Round Ball That Floats in the Air' (1876); 'The Stories Mother Nature Told'; 'The Seven Little Sisters Prove their Sisterhood' (1878); 'Ten Boys on the Road from Long Ago to Now' (1885); 'Only a Year and What It Brought' (1887).

An'drews, John N., an American military officer: b. in Delaware, 1838. He was graduated at West Point in 1860; served with distinction through the Civil War; commissioned colonel of the 12th United States infantry in 1895; and appointed a brigadier-general of volunteers for the war against Spain in 1898.

An'drews, Lorrin, an American missionary: b. East Windsor, Conn., 29 April 1795; d. Honolulu, 29 Sept. 1868. He was educated at Jefferson College and Princeton Theological Seminary; missionary in the Hawaiian Islands, 1827, until, in 1840, from anti-slavery scruples, he resigned connection with the American Board. He became a judge and secretary of the privy council, 1845–55; translated a part of the Bible into Hawaiian and compiled the following works: 'Vocabulary of Words in Hawaiian' (1836); 'Grammar of the Hawaiian Language' (1854); 'Dictionary of the Hawaiian Language' (1865); all published in the island.

An'drews, Samuel James, an American clergyman: b. Danbury, Conn., 31 July 1817. Graduated at Williams College, 1839, he was admitted to the bar in Connecticut and Ohio and practised law in those States 1842–4. He then studied at Lane Theological Seminary; ordained in Congregational ministry, 1846; pastor, East Windsor, Conn., 1848–55; adopted the Irvingite doctrines and has been in charge of a Catholic and Apostolic Church congregation in Hartford, Conn., from 1868 to the present. Author of 'Life of Our Lord Upon Earth' (1862); 'God's Revelations of Himself to Men' (1885); 'Christianity and Anti-Christianity in Their Final Conflict' (1898); 'The Church and Its Organic Ministries' (1899); 'William Watson Andrews: A Religious Biography' (1900).

An'drews, Stephen Pearl, an American author: b. Templeton, Mass., 22 March 1812; d. New York city, 21 May 1886. Educated at Amherst; practised law in New Orleans and Texas. His enthusiastic advocacy of the abolition of slavery took him to England in 1843 to raise money to pay for the slaves and make Texas free. He learned in England phonography, and became the founder in this country of the present system of phonographic reporting, editing journals devoted to it, and publishing numerous instruction books. Early in life he announced the discovery of the unity of law in the universe, and devoted the last half of his life to developing this philosophy, called by him "Integralism," and to the construction of a universal language which he named "Alwato," as a part of this system of "universology." He spoke several languages and is said to have had a knowledge of thirty. In 1882 he instituted the "Colloquium," a series of conferences for the exchange of opinions between leading New York clergymen and others of the widest diversity of religious, philosophical, and political views. His chief works are 'Discoveries in Chinese' (1854); 'Synopsis of Universology and Alwato' (1871); 'Basic Outline of Universology' (1872); 'Grammar of Alwato' (1877); 'Transactions of the Colloquium,' (Vols. I., II., 1882–3); 'The Church and Religion of the Future' (1886).

An'drews, William, an English author and compiler: b. Kirkby Woodhouse, Nottinghamshire, 11 Aug. 1848. He established the Hull Press in 1890, and is the librarian of the Royal Institution at Hull. Among his many publications are 'Old Church Lore' (1891); 'Bygone England' (1892); 'Modern Yorkshire Poets'; 'Historic Byways and Highways'; 'Bygone Punishments.'

An'drews, William Draper, an American inventor: b. Grafton, Mass., 1818; d. 1896. In 1844 he invented the centrifugal pump which made it possible to save goods not injured by water from abandoned wrecks; the pump was manufactured in England as the Gwynne pump; was patented in the United States in 1846. Later he invented and patented the anti-friction centrifugal pump; made various modifications of centrifugal pumps, and patented a widely-used system of gangs of tube-wells.

Androconia, ăn'dro-cō'nĭ-ȧ, certain highly modified scent-scales shaped like battledores, on the wings of certain butterflies and caddis flies (*Trichoptera*). In certain butterflies (*Thecla, Danais*, etc.) they occur on the upper side of the fore wings in limited areas, such as in the discal spots, or they may be scattered in rows or irregularly over the upper surface, or in the folds of the wings. Fritz Müller has shown that these minute scales function as scent-scales, and are confined to the males. Thomas has proved by sections of the wings of *Danais*, etc., that the androconia arise from glands situated in a fold of the wing, and that the material elaborated by the local glands, and distributed upon the surface of the wing by the androconia is that which gives to many of the *Lepidoptera* their characteristic odor. Scudder, who named them, says that they are very capricious in their occurrence. A number of allied genera may possess them, while a single genus, as closely allied, may be quite destitute. They occur in the *Nymphalidæ, Pieridæ, Lycæmidæ, Papilionidæ,* and *Hesperidæ.*

Andromachus, ăn-drŏm'ăk-ŭs, a physician to the Emperor Nero, and the inventor of a celebrated compound medicine called *theriake,* described in Galen's works.

Andronicus I., ăn'dro-nĭ'cŭs (Comnenus), a Byzantine emperor: b. 1110; d. 12 Sept. 1185. In his youth he served against the Turks, in 1141 was for some time a prisoner, and was afterward appointed to a military command in Cilicia, but was unsuccessful. Engaging in a treasonable correspondence with the king of Hungary, he was thrown into prison by his cousin, the Emperor Manuel: but after 12 years he succeeded in making his escape and reached Kiev, the residence of Prince Jaroslav. He regained the favor of his cousin by persuading Jaroslav to join him in the invasion of Hungary, and by his gallantry in that war: but again incurred his displeasure and was sent in honorable banishment to Cilicia. After a pilgrimage to Jerusalem and his scandalous seduction of Theodora, the widow of Baldwin, king of Jerusalem, he settled among the Turks in Asia Minor with a band of outlaws, making frequent inroads into the province of Trebizond; but at length made his peace with the emperor and was sent to Œnoe in Pontus. Upon the death of Manuel in 1182 he was recalled to become, first guardian, then colleague, of the young Emperor Alexius II. Soon after he caused the empress-mother to be strangled, and afterward Alexius himself, whose youthful widow he married. His reign, though short, was vigorous, and restored prosperity to the provinces; but tyranny and murder were its characteristics in the capital. At last a destined victim, Isaac Angelus, one of his relatives, having fled to the Church of St. Sophia for sanctuary, a crowd gathered, and a sudden insurrection placed Isaac on the throne, while Andronicus, now 73 years of age, was put to death by the infuriated populace after horrible mutilations and tortures.

Andronicus of Rhodes, a Roman philosopher who interpreted the works of Aristotle (q.v.). He lived in Cicero's time. None of his known works are extant.

Andropogon, ăn'dro-pō'gŏn, a genus of about 200 species of grasses of very diverse utility, distributed widely, especially over dry plains throughout the temperate and tropical zones. The species are usually characterized by long, narrow leaves; terminal and axillary spikes; sessile perfect spikelets paired with pedicelled staminate, empty ones or scales; and straight or twisted awns. *A. halepensis,* or *Sorghum halepense* of some authors, Johnson grass, attains a height of from 3 to 6 feet from stout, perennial creeping rootstocks, which being difficult to eradicate make the plant a troublesome weed where not needed for pasture or hay, for which it is largely grown in South America, Australia, and the southern United States, where it was introduced about 1830. It makes quick growth, yields abundantly, and may be cut several times in a season. It is not fully hardy in the north, where, as in Europe, it is often grown for ornament. *A. schoenanthus,* lemon grass, and *A. nardus,* citronella grass, are handsome tropical species cultivated in India and Ceylon for the fragrant oils they contain, and which are used in perfumery, soap-making, and in the former case for the adulteration of certain perfumes, notably attar of roses. *A. sorghum,* or *Sorghum vulgare* of some authors, is of wide economic importance, its numerous varieties or sub-species being cultivated for fodder, sugar, alcohol, brushes, brooms, and its seeds, which last are used for poultry, stock, and human food. (See Sorghum.) *A. provincialis, A. scoparius,* and various other species known as blue-stem grass, are valued as fodder grasses in arid regions where they are native.

Andros, Sir **Edmund,** an American colonial governor: born in London, England, 6 Dec. 1637; died there 24 Feb. 1714. His father was master of ceremonies to Charles I.; shared with distinguished service the Stuarts' exile, made his son a page, and put him early into the army of Henry of Nassau. His uncle was cupbearer to Charles' sister, the queen of Bohemia, and in 1660 Edmund was made her gentleman in ordinary. Her adviser in her widowhood was William, Earl of Craven, and Andros in 1671 married the sister of Craven's kinsman and heir. He earned the favor of the Stuarts by steady and laborious service, unwavering loyalty and honor, and a military and executive ability which was equally appreciated by their successors. In 1666 he was made major of an infantry regiment and sent to America, where he won laurels against the Dutch, and in 1672 was titular commander of the British forces in Barbados, with the reputation of being skilled in American affairs. At this time he was in England, and in April 1672 was made major in a regiment of dragoons raised for Prince Rupert; also a "landgrave" in Carolina, two years later succeeding his father as bailiff of Guernsey.

In 1674 Andros was made "lieutenant and governor" of "all the Duke of York's territories in America," including New York (just restored by the Dutch, who had retaken it the year before), New Jersey, and Delaware, Martha's Vineyard, and parts of Maine, and a claim to all Connecticut west of that river. He arrived in November, and the next year began to push the Connecticut claim; but the duke did not desire an appeal to force, and after making formal declarations at Saybrook, Andros retired. During the next two years the Indian troubles were acute; and he proved himself one of the ablest

and most useful of Indian managers, winning the good will of the Iroquois at a critical time, and not only keeping his own colony protected, but sending help to the outlying points in Rhode Island, Massachusetts, and Maine. He spent a few months in England in 1677–8, and was knighted. In 1678–80 there was increasing friction, religious and otherwise. He was an Episcopalian, and one of his appointees to a coadjutorship in an Albany church was tried for heresy, but acquitted; Andros, however, tactfully quieted the disturbance and contributed to build a Reformed church in New York. Then the merchants charged him with unfairness in trade matters, and with suppressing part of his receipts in his public accounts, with the object of inducing James to sell to some of them the right to farm the New York revenues. At this period Philip Carteret was acting as governor of East Jersey under the Duke of York's grant to his brother and Berkeley; there were complications inherited from previous changes which forced Andros to keep interfering, under his superior commission, and at last he sent a body of soldiers to seize Carteret and bring him to New York, to be tried for exercising illegal jurisdiction. Andros acted as judge, but the jury acquitted Carteret, who was triumphantly reinstalled. Lady Carteret complained to James, who recalled Andros, and sent out a commissioner to investigate this and the other charges: he reported that Andros was not in fault, but the latter was retained at home, made gentleman of the privy chamber to Charles II., and received a 99-years' grant of the island of Alderney and other favors.

The accession of James II. (February 1685), brought him a great though ill-starred position, which has loaded his memory with unjustifiable abuse. The Massachusetts charter had been vacated in October 1684, and Charles II. had appointed the notorious Col. Piercy Kirke governor; but as he never entered on his duties, Andros was commissioned governor of all New England as one consolidated colony on 3 June 1686. Dislike to James has done injustice to the scheme, which was statesmanlike, distasteful as it was to the New Englanders: to make one powerful province with a militia army strong enough to resist French and Indian aggression, and under one command, instead of several weak ones fighting each other rather than the common enemy. As to Andros, the plan was not his, there is no evidence that he sought the place, there was no reason why he should not accept it, and there was no way to execute it but the one he adopted: we cannot justify the end and blame the indispensable means. He could only be blamed for needless harshness or blundering or corruption in obeying his instructions: and despite the current opinion there was none of this, but rather the reverse. On arriving at Boston, 19 Dec. 1686, he organized his new government, which, as the people had no longer the right to tax themselves, levied a new tax, which, however, was exactly the same as the old. Ipswich refused to pay, and the ringleaders were fined and imprisoned, as must happen under any law. He was ordered to proclaim all land titles invalid unless confirmed by the Crown for a quit-rent. Outrageous as this may seem, it was held to be sound law, and he enforced it in the most humane way by bringing test suits against a few of the wealthiest citizens before proceeding further. As a fact, only a part had yielded when the Revolution interrupted it. He granted waste common-lands to individuals who would improve: a venial crime. Heavy fees were charged by the public officials; but he neither fixed the rates, received the proceeds, nor appointed the officers who did. He had Episcopal services held in the Old South Church, but only when its regular congregation was not using it; this sacrilege, however, has blackened his memory worse than anything else. He was sometimes sharp in speech; but when some wickedly foolish people charged him with secretly fomenting an Indian war, he only laughed at them and left the courts to attend to the matter. In a word, there was neither a political nor a religious reign of terror set up: no one was persecuted for nonconformity, or executed or whipped for political offenses. Andros behaved like a statesman, an honest man, and a humane one. He early extended his authority over Plymouth, New Hampshire, and Rhode Island, as well as Maine and Massachusetts. In October 1687 he visited Hartford, to take up the Connecticut charter: the story of its being hidden in the Charter Oak is classic, and it is certain enough that one copy was hidden and was efficient in restoring the charter rights of the colony later; but there was another copy and the event was of no significance at the time. Andros, on returning to Boston in 1688, received the news that he was made governor also of all the British provinces in America except Pennsylvania, Delaware, Maryland, and Virginia. While making a tour of his northern provinces he was checked by the information that the Penobscot Indians, stirred up by Castine (q.v.), whose property had been taken, were about to go on the war-path. He collected 700 troops, and in November proceeded to Maine and garrisoned several posts. On 4 April 1689 news was received of the deposition of James II.; on the 18th the citizens rose and captured Andros, and kept him prisoner till 2 August, when he escaped to New York, but was recaptured and brought back, and not released till February 1690. William III. needed officials as able and upright as he, and in 1692 made him governor of Virginia. He carried with him the charter of William and Mary College, and till 1698 remained in Virginia, a most public-spirited, hard-working, excellent ruler, doing much for the progress of the colony and esteemed by its people. His removal was caused by a quarrel with the commissary of the Bishop of London, and president of the college, who quarreled with all the governors. He was governor of Guernsey 1704–6, and bailiff of the island for life. He had been governor of every mainland English province in North America, and won the esteem of four successive monarchs, of hostile lines. Even for New England, his departure was not an unmixed good, for it was followed by one of her bloodiest and most disastrous Indian wars, which his presence might have averted.

An'dros Islands, a group of islands of the West Indies belonging to the English colony of the Bahamas, about 150 miles southeast of Florida.

Anemometer, ăn-e-mŏm'e-tėr (from the Greek words *anemos*, "wind," and *metron*, "measure"), an instrument for measuring the velocity of an air current, or the force such a current exerts against an obstacle. The two problems here suggested are widely different in nature; for while the *velocity* of an air current can easily be obtained with a fair degree of precision, the determination of the wind *pressure* exerted against buildings and other structures involves many considerations that cannot be overlooked without falsifying the results. The problem of wind pressure is so complicated, in fact, that the numerous forms of apparatus proposed for its solution are mostly unreliable, misleading, and incapable of furnishing even approximate values of the real forces in play. For further discussion of the force of the wind see WIND.

Of the numerous forms of anemometer proposed for the determination of the velocity of an air current, only two are in general use. These are (1) Robinson's, and (2) Casella's. The Robinson instrument is designed for meteorological use, and consists of four hemispherical cups, mounted upon horizontal arms, and capable of rotating freely about a vertical axis. The wind strikes the convex surfaces of the cups on one side of the axis of rotation, and the concave surfaces on the other side; and as it exerts more force against a concave surface than against an equal convex one, the system of arms and cups is caused to rotate continuously, with a speed depending upon the velocity of the wind. Dr. Robinson, the inventor of this type of instrument, concluded that the linear speed of the centre of the cups is one third of the velocity of the wind causing the rotation, but it is now certain that this ratio varies somewhat with the proportions of the arms and cups, and that the real velocity of the wind may be from 2.5 to 3.5 times as great as that of the centre of the cups. Before accurate results can be obtained from a Robinson anemometer of given proportions it is therefore necessary to determine the constant of this particular design of instrument experimentally, either by exposing it by the side of another instrument previously studied, or by whirling it through the air at the extremity of a revolving arm whose speed of rotation is known. The Robinson anemometer is the official instrument of the United States Weather Bureau for the measurement of wind-velocities.

The Casella anemometer is designed for measuring the velocities of air currents in mines, ventilating shafts, and like places. It consists essentially of a set of spokes radiating from an axis and each carrying at its extremity a small fan or blade, set at an oblique angle to the central shaft. The instrument is placed in the current whose velocity is to be measured, its axis of rotation being set parallel to the direction of flow of the air. The velocity of the current is determined by observing the number of revolutions made by the fan in a given time, as recorded upon a graduated dial whose index is actuated by the fan, through a suitable train of wheels. In some forms of the Casella anemometer a half-minute sand glass is provided, which, when inverted, automatically throws the recording needle into gear and out again. It is hardly necessary to add that the Casella instrument, like the Robinson, must be carefully tested by experiment, or by comparison with another instrument which has been so tested, before its indications can be considered reliable.

(See Abbe's 'Meteorological Apparatus and Methods,' also Prof. C. F. Marvin's paper in the 'Report, for 1890, of the Chief Signal Officer of the United States Army.')

Anemone, ă-nĕm'o-ne, wind-flower, a genus of plants belonging to the Buttercup family (*Ranunculaceæ*) containing many species found in temperate regions. Many of them occur in the United States, where their bloom whitens the fields in spring and summer. The most important are: *A. nemorasa*, the common wood-anemone; flowers white, externally tinged with purple; *A. patens mittalania*, the American Pasque flower; *A. quinquefolia*, *A. caroliniana*, and *A. narcissiflora*, found in mountainous regions.

An'eroid Barometer, a species of barometer in which no fluid is employed, an ingenious and delicate instrument invented by M. Vidi, of France, in 1844. Its mechanism consists of a hollow metal cylinder, with thin and corrugated ends, which contract or expand according to the pressure of the atmosphere, the air within having been previously exhausted by the air-pump. The motion of the ends of the cylinder acts upon a principal lever attached to it, and connected with two smaller levers, to one of which a chain is attached, working upon a roller, and to the axis of the roller a hand is fixed, exhibiting the variations of the atmosphere by means of an index on the face of the barometer. A pocket aneroid is very useful for measuring small heights. See BAROMETER.

An'eurism, a disease of the walls of the arteries resulting in the formation of a pulsating sac or swelling. At times the disease process leads to rupture of the walls of the blood-vessels with an extravasation of blood into the adjacent tissues, making a tumor-like formation. Such an aneurismal swelling is known as a false aneurism. In the true aneurism the sac is formed by one or more of the arterial coats. True aneurisms vary in shape and size, being fusiform, cylindrical, cirsoid (in which a branch of the artery is included in the swelling), circumscribed, or sacculated. Most aneurisms are fusiform, the dilatation of the vessel usually being uniform. Another type of aneurism usually occurring in the aorta is known as a dissecting aneurism. In this the inner wall of the artery ruptures and the blood dissects its way between the coats of the artery wall. When an aneurismal swelling occurs at the junction of an artery and a vein, an arterio-venous aneurism results. Aneurismal varix is a type of this form of aneurism.

The causes of aneurisms are manifold. The most important feature is a chronic disease of the connective tissue of the blood-vessels, arterio-sclerosis (q.v.) that results in the weakening of the wall and gradual distention of the vessel with the formation of a sac. The symptoms are often extremely obscure and depend in large part on the presence of a tumor that makes pressure symptoms on important organs. These will vary widely according to the situation of the aneurism. The treatment is largely surgical and the details are dependent upon the variety and situation of the aneurismal swelling.

Angel of the Battlefield. See ANTHONY, SISTER.

Angell, ăn'jĕl, **George Thorndike,** American reformer: b. Southbridge, Mass., 1823. He was graduated at Dartmouth College in 1846, and admitted to the bar in 1851. He has been active in promoting measures for the prevention of crime, cruelties, and the adulteration of food. He founded and is president of the American Humane Educational Society.

Angell, James Burrill, an American educator: b. in Scituate, R. I., 7 Jan. 1829. He was graduated from Brown University in 1849; and was professor of modern languages and literature there, 1853–60; editor Providence *Journal*, 1860–6; president of the University of Vermont, 1866–71; president of the University of Michigan since 1871. United States minister to China, 1880–1; minister to Turkey, 1897-8; member of the Anglo-American Commission on Canadian Fisheries, 1887, and of the Deep Waterways Commission, 1896. Author of 'Manual of French Literature' (1857); 'Progress in International Law' (1875); and many articles in the leading American reviews.

Angell, Joseph Kinnicut, an American legal writer: b. Providence, R. I., 30 April 1794; d. Boston, Mass., 1 May 1857. Graduated at Brown University, 1813. Edited the 'Law Intelligencer and Review,' 1829–31, and prepared the first published law reports of Rhode Island. Alone or in collaboration he produced a number of valuable and much used legal textbooks, chief of which are, 'Treatise on Corporations' (4th ed. 1858), highly commended by Chancellor Kent; 'Common Law in Relation to Watercourses' (4th ed. 1850); 'Liabilities and Rights of Common Carriers' (2d ed. 1845); 'Law of Fire and Life Insurance.'

Angelo, ăn'jĕlō, **Michael.** See MICHELANGELO.

Angelus, the Catholic prayer and practice by which the mystery of the Incarnation is recalled to mind and is honored, morning, noon, and evening. It forms the subject of a famous painting by Millet (q.v.).

Angi'na Pec'toris, a symptom of disordered heart action, frequently called a neurosis. It is a rare disease and is characterized by paroxysmal attacks of excruciating pain in the heart region. These pains frequently radiate into the arms and neck and sometimes are so severe as to cause a sense of suffocation and fear of death. It is a suffocative breast pang. True angina pectoris — for there are false varieties that occur largely in hysterical and neurasthenic women — often causes death, whereas the false variety is rarely as severe and never fatal. Men are more frequently affected than women, and it is a disease of adult life. It is sometimes found in families for several generations. Gout, syphilis, diabetes, excessive tea or coffee drinking, and even influenza are important factors in bringing about certain changes in the arteries, notably the coronary arteries of the heart, that are nearly always found as concomitants of this condition. This change of the arteries is a true arterio-sclerosis (q.v.). The attacks are usually brought on by sudden acute exercise, or by marked emotional excitement, notably worry and anger.

References.— Osler, 'Lectures on Angina Pectoris' (1897); Hoffman, 'Die Herzneurosen und die funktionellen Kreislaufstörungen' (1903).

An'gle, the point where two lines meet, or the meeting of two lines in a point. Technically, the inclination of two lines to one another. A plane angle is the inclination of two lines to one another in a plane, which two lines meet together. A solid or polyhedral angle is that made by the meeting in one point of more than two plane angles, which, however, are not in the same plane. A dihedral angle is formed by the intersection of two planes. Angles may again be subdivided into rectilinear, curvilinear, and mixed angles. A plane rectilinear angle is the inclination to each other of two straight lines which meet but are not in the same straight line. A curvilinear angle is the inclination to each other of two curved lines which meet in a point, and is equal to the inclination of the tangents to the curves at their intersection. A mixed angle is one formed by the meeting of a curve and a straight line.

Angles are measured by arcs, and it is immaterial with what radius the latter are described. The result is generally stated in degrees, minutes, and seconds $^{\circ}\ '\ ''$; thus $36^{\circ}\ 14'\ 23'' =$ 36 degrees, 14 minutes, and 23 seconds. Angles are also measured in radians, a radian being the arc equal to the radius of the circle, or about 57.3°. The quadrant, or right angle, is also a convenient unit for many purposes. When an angle is isolated from other angles it may be named by a single letter; but when two or more angles meet at one point they are named by three letters, never by one or two. In such cases the letter at that point is always named in the middle. The point at which the lines forming the angle meet is called the angular point or vertex of the angle, and the lines themselves are called the sides or legs of the angle.

Plane rectilinear angles are generally divided into right and oblique, or into right, obtuse, and acute. When a straight line standing upon another straight line makes the two adjacent angles (those on the right and left of it) equal to one another, each of them is called a right angle. An oblique angle is one which is not a right angle. An obtuse angle is that which is greater than one right angle, but less than two. An acute angle is that which is less than a right angle: both are oblique. A spherical angle is one formed by the intersection or the meeting of two great circles of a sphere.

An'gle Iron. See RAILS AND STRUCTURAL SHAPES.

An'gler. See GOOSEFISH.

An'gles, a German tribe who probably lived originally on the east side of the Elbe, between the Saale and Ohre rivers, whence they moved to what is now the district of Angeln in Schleswig-Holstein, lying between the territories of the Jutes and Saxons. They never approached the Rhine and the Roman frontiers, hence we do not find their name mentioned by the Roman authors, who comprehended them, with many others, under the general name of Chauci and Germani, till the conquest of Britain made them better known as a separate nation. In the 5th century they joined their powerful

northern neighbors, the Saxons, and took part in the conquest of Britain, which from them derived its future name of England. A part remained in their Continental homes and gave their name also to the district of Angeln.

Anglesey, ăn'gl'-sē, **Henry William Paget, Marquis of,** an English soldier and statesman: b. 1768; d. 1854. He was educated at Oxford, and in 1790 entered Parliament as member for the Carnarvon boroughs. In 1794 he took part in the campaign in Flanders under the Duke of York, and in 1808 was sent into Spain with two brigades of cavalry to join Sir John Moore, and in the retreat to Coruña commanded the rear guard. In 1812 he became, by his father's death, Earl of Uxbridge. On Napoleon's escape from Elba he was appointed commander of the British cavalry, and at the battle of Waterloo overthrew the Imperial Guard. For his services he was created Marquis of Anglesey. In 1828 he became lord-lieutenant of Ireland and made himself extremely popular, but was recalled in consequence of favoring Catholic emancipation. He was again lord-lieutenant in 1830; but lost his popularity by opposition to O'Connell and his instrumentality in the passing of the Irish coercion acts, and he quitted office in 1833.

Anglesey, ăn'gl'-sē, or **Anglesea,** an island and county of North Wales, in the Irish Sea, separated from the mainland by the Menai Strait. It is about 20 miles long and 17 miles broad, with an area of 175,836 acres, of which fully 150,000 acres are under rotation crops and permanent pasture, exclusive of mountain and heath land used for pasturage (about 7,600 acres). It is divided into three *cantrefs*, and each of these into two *cwmwds,* equivalent to the English hundreds. The surface of the island, with the exception of Holyhead, Parys, and Bodafon Mountains, is comparatively flat, and the climate, though milder than that of the adjoining coast, is not so favorable to the growth of trees. There are no streams of any importance, but the coast affords some natural harbors, the principal of which are Holyhead and Beaumaris. The principal crops are oats, barley, turnips, and potatoes. Cattle and sheep are the staple productions of the island, and large numbers of both are annually exported. Of minerals, Anglesey contains copper, lead, and silver ore, limestone, marble, asbestos, and marl, but the copper mines at Parys and Mona, once so celebrated and productive, have much decreased in value. The Menai Strait is crossed by a magnificent suspension-bridge, 580 feet between the piers and 100 feet above high-water mark, allowing the largest vessels which navigate the strait to sail under it; and also by the great Britannia Tubular Bridge, for the conveyance of railway trains, Holyhead being the point of departure for the Irish mails. The market towns are Holyhead, Beaumaris, Llangefni, and Amlwch, the first-named by far the largest. The county itself returns a member to Parliament. On the coast are several small islands, the chief being Holyhead and Puffin Island. Pop. (1901) 50,590.

An'glesite, ăn'gle-sīt (from the island of Anglesea, where it was first observed, a native sulphate of lead, $PbSO_4$. It crystallizes in the orthorhombic system and has a hardness of from 2.75 to 3, and a specific gravity varying from 6.1 to 6.4. It may be transparent or opaque, and in color white, greenish, yellowish, or gray. It occurs in many localities, usually in connection with galena, whence it is apparently derived by oxidation. Beautiful transparent crystals of it, several inches in diameter, are known. Anglesite, in a massive form, is extensively mined as an ore of lead (q.v.).

An'gleworm. See EARTHWORM.

An'glia, East, an English kingdom founded by the Angles (q.v.) in the 6th century in the eastern part of England in what now forms the present counties of Norfolk and Suffolk. It was conquered by the Danes in 878, and became part of the English kingdom in 921, under Edward, son and successor of Alfred. The modern see of Norwich corresponds in extent to the East Anglian kingdom, and the name East Anglia is still frequently employed to denote these two shires.

An'glican Church. See CHURCH OF ENGLAND.

An'glin, Margaret, an American actress: b. in Ottawa, Canada, 1876. She studied at the Empire School of Dramatic Acting in New York city and made her début in 1894 in 'Shenandoah.' Her roles include Roxane with Mansfield in 'Cyrano de Bergerac,' Mimi in 'The Only Way,' Mrs. Dane in 'Mrs. Dane's Defense,' and Mabel Vaughn in 'The Wilderness.'

An'gling is one of the words which have made themselves a specific meaning that has eluded the lexicographer, or nearly so. Of course it is, as he says, "to fish with an angle or rod and line and bait": but to those of the craft it is so much more and so much less. It is to fish in a certain way, and not with any rod and line and bait. When the real disciple of the gentle Izaak uses the words «Let us go angling,» it means Let us wander away with the lightest of bamboo rods, the multiplying reel, the thinnest and most perfect of lines, and a book full of artificial flies. Angling is for the knights of the craft, and for the kings of fighting fish.

After fixing the separate pieces of his rod together and attaching the winch on which his line is wound, the angler passes the line through the rings along the length of the rod, and through the loop at the top. He then attaches a length of gut, and on that he fastens the artificial-fly hook. After unwinding as much of the line as will be necessary to reach the spot on the water where he thinks the fish is, he is ready for the sport. There are two schools of fly-casters among anglers, the old-fashioned wet caster, who was not restricted to any number of flies, and who moved up or down the stream casting frequently as he went, and the modern school of dry casters who restrict themselves to a single artificial fly, made very small, dressed with upstanding wings, so as to ensure its floating on the surface, and sometimes anointed with an odorless oil to keep it dry. The dry caster remains inactive until the trout is seen to rise.

In either school the casts are divided into six classes: the overhand, the underhand, the spray cast, the wind cast, the flip cast, and the switch cast. The object of them all is to cause

the fly to fall upon the water as if it were a natural fly which had alighted on the surface in its natural habit, or had fallen off some overhanging branch, or been blown from the grass and was floating down stream. The most commonly used cast is the overhand. To perform it the angler standing on the river's brim unwinds a few yards of his line and lets the fly float down stream, raising his rod until it is at an angle of some 60 to 80 degrees in front of him. With a swift movement of the wrist, he lifts it so that it passes over his shoulder: the line follows and passes away beyond it. At a moment only to be learned from experience, but which every angler soon feels, he throws the rod forward and onward in the direction in front of him which he wants the fly to take, and it falls there, gently. This cast is possible wherever there are neither trees nor rocks for the necessary distance behind the angler. When these are present the switch cast is used: in that the fly is drawn along the top of the water toward the angler's feet, and then, lowering his rod by a quick downward movement, the line is sent forward rolling over and over itself in curves. When all the curves are unwound the fly falls back into the water at the extreme end of the line. The first movements in the wind cast are the same as those of the switch cast: the difference is in the thrash by which the line is made to travel up against the wind. The flip cast is made by taking the fly between the thumb and finger, pulling the top of the rod down until it is a bow, and then letting it slip back. The force will carry the fly to the desired spot. The spray cast is used now when a great length of line is out. The fly is then drawn up to the feet of the angler and the pole thrown forward up stream, not, as in the overhead cast, swished behind the line of the shoulders.

An'glo-Amer'ican Commission, a joint international commission appointed in 1898 by the United States and Great Britain for the negotiation of a plan for the settlement of all controversial matters between the United States and Canada. The subjects submitted for the consideration of the commission were officially determined as follows: "The Behring Sea sealing question, reciprocal mining regulations, the preservation of the fisheries of the Great Lakes, the North Atlantic fishery question, the boundary question, the alien labor laws, and reciprocity of trade." Lord Herschell, Sir Wilfred Laurier, Sir Richard Cartwright, Sir Louis H. Davies, and Mr. J. Charlton, a member of the Dominion Congress, were appointed British commissioners. The American commissioners were United States Senators Fairbanks and Gray, Congressman Dingley, Reciprocity Commissioner Kasson, and ex-Secretary of State Foster. The commission met at Quebec, 23 August, Lord Herschell being chosen chairman; W. C. Cartwright, of the Foreign Office, and H. Bourassa, member of Parliament for Labelle County, Quebec, were chosen British secretaries, and C. P. Anderson United States secretary. Later in the year an adjourned session was held in Washington, D. C., which adjourned without practical results.

An'glo-Amer'ican League, The, an organization formed 13 July 1898 at a meeting held at Stafford House, London. Its object is to give practical effects to the terms of the following resolution, passed at that meeting:

"Considering that the peoples of the British Empire and of the United States of America are closely allied in blood, inherit the same literature and laws, hold the same principles of self-government, recognize the same ideas of freedom and humanity in the guidance of their national policy, and are drawn together by strong common interests in many parts of the world, this meeting is of opinion that every effort should be made, in the interest of civilization and peace, to secure the most cordial and constant co-operation between the two nations."

Membership is open to all British subjects and citizens of the United States. A strong and representative committee was formed, with the Right Hon. James Bryce, M. P., as chairman.

An'glo-Cath'olic, a term applied to those members of the Anglican communion whose beliefs and religious forms most nearly approach those of the Roman Catholic Church. Ritualists, as Anglo-Catholics are frequently called, lay especial emphasis on the "Catholic principles" of apostolic succession, regeneration in baptism, the Eucharistic real presence, and the authority of tradition.

An'glo-Is'raelite The'ory, a peculiar belief as to English origins. It assumes that the English are descended from the lost 10 tribes of Israel; but the theory is untenable on any scientific grounds, for the tribes vanished through absorption in neighboring peoples and were not lost in any real sense. See Streator, 'The Anglo-Alliance in Prophecy, or the Promises to the Fathers' (1900).

Anglo-Japanese Treaties. The first treaty between England and Japan was signed 30 Jan. 1902. The text is as follows:

The Governments of Great Britain and Japan, actuated solely by a desire to maintain the status quo and general peace in the extreme East, being moreover specially interested in maintaining the independence and territorial integrity of the Empire of China and the Empire of Korea, and in securing equal opportunities in those countries for the commerce and industry of all nations, hereby agree as follows:

Article 1. The High Contracting Parties, having mutually recognised the independence of China and Korea, declare themselves to be entirely uninfluenced by any aggressive tendencies in either country. Having in view, however, their special interests, of which those of Great Britain relate principally to China, while Japan, in addition to the interests which she possesses in China, is interested in a peculiar degree politically, as well as commercially and industrially, in Korea, the High Contracting Parties recognise that it will be admissible for either of them to take such measures as may be indispensable in order to safeguard those interests if threatened either by the aggressive action of any other Power, or by disturbances arising in China or Korea, and necessitating the intervention of either of the High Contracting Parties for the protection of the lives and property of its subjects.

Article 2. If either Great Britain or Japan, in the defence of their respective interests as above described, should become involved in war with another Power, the other High Contracting Party will maintain a strict neutrality, and use its efforts to prevent other Powers from joining in hostilities against its ally.

Article 3. If in the above event any other Power or Powers should join in hostilities against that ally, the other High Contracting Party will come to its assistance, and will conduct the war in common, and make peace in mutual agreement with it.

Article 4. The High Contracting Parties agree that neither of them will, without consulting the other, enter into separate arrangements with another Power to the prejudice of the interests above described.

Article 5. Whenever, in the opinion of Great Britain or Japan, the above-mentioned interests are in jeopardy, the two Governments will communicate with one another fully and frankly.

Article 6. The present agreement shall come into effect immediately after the date of its signature, and remain in force for five years from that date. In case neither of the High Contracting Parties should have notified twelve months before the expiration of the said five years the intention of terminating it, it shall remain binding until the expiration of one year from the day on which either of the High Contracting Parties shall have denounced it. But if, when the date fixed for its expiration arrives, either ally is actually engaged in war, the alliance shall, ipso facto, continue until peace is concluded.

The second treaty was signed at London 12 Aug. 1905. The following letter explains its objects and purposes.

Despatch to his Majesty's Ambassador at St. Petersburg, forwarding a copy of the Agreement between the United Kingdom and Japan, signed at London, Aug. 12, 1905.

The Marquis of Lansdowne to Sir C. Hardinge

Foreign Office, Sept. 6, 1905.

Sir, — I inclose, for your Excellency's information, a copy of a new Agreement concluded between his Majesty's Government and that of Japan in substitution for that of Jan. 30, 1902. You will take an early opportunity of communicating the new Agreement to the Russian Government.

It was signed on Aug. 12, and you will explain that it would have been immediately made public but for the fact that negotiations had at that time already commenced between Russia and Japan, and that the publication of such a document whilst those negotiations were still in progress would obviously have been improper and inopportune.

The Russian Government will, I trust, recognise that the new Agreement is an international instrument, to which no exception can be taken by any of the Powers interested in the affairs of the Far East. You should call special attention to the objects mentioned in the preamble as those by which the policy of the contracting parties is inspired. His Majesty's Government believe that they may count upon the goodwill and support of all the Powers in endeavouring to maintain peace in Eastern Asia, and in seeking to uphold the integrity and independence of the Chinese Empire and the principle of equal opportunities for the commerce and industry of all nations in that country.

On the other hand, the special interests of the contracting parties are of a kind upon which they are fully entitled to insist, and the announcement that those interests must be safeguarded is one which can create no surprise, and need give rise to no misgivings.

I call your especial attention to the wording of Article II., which lays down distinctly that it is only in the case of an unprovoked attack made on one of the contracting parties by another Power or Powers, and when that party is defending its territorial rights and special interests from aggressive action, that the other party is bound to come to its assistance.

Article III., dealing with the question of Korea, is deserving of especial attention. It recognises in the clearest terms the paramount position which Japan at this moment occupies and must henceforth occupy in Korea, and her right to take any measures which she may find necessary for the protection of her political, military, and economic interests in that country. It is, however, expressly provided that such measures must not be contrary to the principle of equal opportunities for the commerce and industry of other nations. The new Treaty no doubt differs at this point conspicuously from that of 1902. It has, however, become evident that Korea, owing to its close proximity to the Japanese Empire and its inability to stand alone, must fall under the control and tutelage of Japan.

His Majesty's Government observe with satisfaction that this point was readily conceded by Russia in the Treaty of Peace recently concluded with Japan, and they have every reason to believe that similar views are held by other Powers with regard to the relations which should subsist between Japan and Korea.

His Majesty's Government venture to anticipate that the alliance thus concluded, designed as it is with objects which are purely peaceful and for the protection of rights and interests the validity of which cannot be contested, will be regarded with approval by the Government to which you are accredited. They are justified in believing that its conclusion may not have been without effect in facilitating the settlement by which the war has been so happily brought to an end, and they earnestly trust that it may, for many years to come, be instrumental in securing the peace of the world in those regions which come within its scope. — I am, &c.,

(Signed) Landsdowne.

The text is as follows:

Inclosure. Agreement between the United Kingdom and Japan, signed at London, Aug. 12, 1905.

Preamble. The Governments of Great Britain and Japan, being desirous of replacing the Agreement concluded between them on Jan. 30, 1902, by fresh stipulations, have agreed upon the following articles, which have for their object: —

(a) The consolidation and maintenance of the general peace in the regions of Eastern Asia and of India;

(b) The preservation of the common interests of all Powers in China by insuring the independence and integrity of the Chinese Empire and the principle of equal opportunities for the commerce and industry of all nations in China;

(c) The maintenance of the territorial rights of the High Contracting Parties in the regions of Eastern Asia and of India and the defence of their special interests in the said regions:

Article 1. It is agreed that whenever, in the

opinion of either Great Britain or Japan, any of the rights and interests referred to in the preamble of this Agreement are in jeopardy, the two Governments will communicate with one another fully and frankly, and will consider in common the measures which should be taken to safeguard those menaced rights or interests.

Article 2. If by reason of unprovoked attack or aggressive action, wherever arising, on the part of any other Power or Powers either contracting party should be involved in war in defence of its territorial rights or special interests mentioned in the preamble of this Agreement, the other contracting party will at once come to the assistance of its ally, and will conduct the war in common, and make peace in mutual agreement with it.

Article 3. Japan possessing paramount political, military, and economic interests in Korea, Great Britain recognises the right of Japan to take such measures of guidance, control, and protection in Korea as she may deem proper and necessary to safeguard and advance those interests, provided always that such measures are not contrary to the principle of equal opportunities for the commerce and industry of all nations.

Article 4. Great Britain having a special interest in all that concerns the security of the Indian frontier, Japan recognises her right to take such measures in the proximity of that frontier as she may find necessary for safeguarding her Indian possessions.

Article 5. The High Contracting Parties agree that neither of them will, without consulting the other, enter into separate arrangements with another Power to the prejudice of the objects described in the preamble of this Agreement.

Article 6. As regards the present war between Japan and Russia, Great Britain will continue to maintain strict neutrality unless some other Power or Powers should join in hostilities against Japan, in which case Great Britain will come to the assistance of Japan, and will conduct the war in common, and make peace in mutual agreement with Japan.

Article 7. The conditions under which armed assistance shall be afforded by either Power to the other in the circumstances mentioned in the present Agreement, and the means by which such assistance is to be made available, will be arranged by the naval and military authorities of the contracting parties, who will from time to time consult one another fully and freely upon all questions of mutual interest.

Article 8. The present Agreement shall, subject to the provisions of Article VI., come into effect immediately after the date of its signature, and remain in force for ten years from that date.

In case neither of the High Contracting Parties should have notified twelve months before the expiration of the said ten years the intention of terminating it, it shall remain binding until the expiration of one year from the day on which either of the High Contracting Parties shall have denounced it. But if, when the date fixed for its expiration arrives, either ally is actually engaged in war, the alliance shall, ipso facto, continue until peace is concluded.

In faith whereof, the undersigned, duly authorised by their respective Governments, have signed this Agreement, and have affixed thereto their seals.

Done in duplicate at London, the 12th day of August, 1905.

LANDSDOWNE,

His Britannic Majesty's Principal Secretary of State for Foreign Affairs.

TADASU HAYASHI,

Envoy Extraordinary and Minister Plenipotentiary of His Majesty the Emperor of Japan at the Court of St. James.

Thus it will be seen that whereas the first treaty referred to China and Korea exclusively, and only became operative upon the intervention of a third Power, the treaty which is superseded applies also «to the regions of Eastern Asia and of India,» and becomes operative when either party to the agreement becomes the object of wanton attack or aggression with respect to the special interests in the regions coming within the scope of the agreement. In effect this new treaty guarantees the *status quo* for very nearly the entire continent of Asia, of course omitting Turkey. England will have Japan's support to withstand any foreign aggression in Persia and Afghanistan or against India, while Japan has the offensive and defensive backing of England in the new relations which she occupies toward Asiatic countries. The terms of this treaty are eminently satisfactory to neutral nations in that they practically give the «open-door» to all and present vast permanent commercial opportunities. Many of the principles agreed upon and incorporated in the agreement were known before the Battle of the Sea of Japan.

An'gloman'ia, a term denoting undiscriminating imitation of everything English on the part of persons of other nationalities. In the United States it is applied to a recent fad of fashionable society.

An'glo-Sax'on, the name given by modern historians to the Angles, Jutes, and Saxons who migrated to Britain from Germany in the 5th and 6th centuries A.D. They emigrated from the districts about the mouths of the Elbe and Weser, and the first body of them who gained a footing in England are said to have landed in 449, and to have been lead by Hengist and Horsa. The Jutes settled chiefly in Kent, the Saxons in the southern and middle country, and the Angles in the northern. Among the various Anglo-Saxon states that afterward arose those founded by the Angles first gained the preponderance, and gave to the whole country the name of *Engla-land*, that is, the land of the Angles.

Among the Anglo-Saxons we find the English constitution already existing in all its essentials, but its origin is not to be attributed to Alfred, though he brought it to a greater pitch of completeness. In a rudimentary form it was the common property of the Germanic peoples before the emigration of the Saxons and Angles from the Continent. It developed itself more independently, however, among the Anglo-Saxons than among those Teutonic races who came into closer connection with the Romans, and afterward with the Roman hierarchy. The Anglo-Saxon community was frequently spoken of as consisting of the *eorls* and the *ceorls*, or the nobles and common freemen. The former were the men of property and position, and were themselves divided into different ranks;

the latter were the small landholders, handicraftsmen, etc., who generally placed themselves under the protection of some nobleman, who was hence termed their *hlaford* or lord. Besides these there was the class of the serfs or slaves (*theowas*), who might be either born slaves or freemen who had forfeited their liberty by their crimes, or whom poverty or the fortune of war had brought into this position. They served as agricultural laborers on their masters' estates, and though mere chattels, as absolutely the property of their master as his cattle, their lot does not appear to have been very uncomfortable. They were frequently manumitted by the will of their master at his death, and were also allowed to accumulate savings of their own, so as to be able to purchase their freedom or that of their children.

One of the peculiar features of Anglo-Saxon society was the *wergyld*, or life-price, established for the settling of feuds. "A sum, paid either in kind or in money where money existed, was placed upon the life of every freeman according to his rank in the state, his birth, or his office. A corresponding sum was settled for every wound that could be inflicted upon his person; for nearly every injury that could be done to his civil rights, his honor, or his domestic peace; and further fines were appointed according to the peculiar adventitious circumstances that might appear to aggravate or extenuate the offense. From the operation of this principle no one was exempt, and the king as well as the peasant was protected by a wergyld, payable to his kinsmen and his people" (Kemble, 'Saxons in England').

The king (*cyning, cyng*) was at the head of the state; he was the highest of the nobles and the chief magistrate. He was not looked upon as ruling by any divine right, but by the will of the people, represented by the *witan*, or Great Council of the nation. Accordingly we find that the new king was not always the direct and nearest heir of the late king, but one of the royal family whose abilities and character recommended him for the office. The king was invested with certain honors and privileges in order that he might maintain his position with becoming dignity. Besides his wergyld as an ætheling or person of royal blood, his life was further guarded by a sum of equal amount, called *cynebót*, or price of royalty, and the former sum was to be paid to his relations, the latter to the people. As king he held possession of the Crown lands, which were national property, distinct from any private estates he might himself purchase. Among other privileges he was entitled to a portion of the fines and confiscations laid upon offenders; he had the right of maintaining a standing army of household troops, the duty of calling together the Council of the Witan, and of laying before them measures which concerned the welfare of the state, with certain distinctions of dress, dwelling, etc., all his privileges being possessed and exercised by the advice and consent of the *witena-gemót*, or Parliament.

The queen also was held in high honor. She sat by the king in the assemblies, and she possessed a separate establishment from that of the king, though on a smaller scale. Next in rank and dignity to the king were the *ealdormen*. These were at the head of the administration of justice in the shires, possessing both judicial and executive authority, and had as their officers the *scir-geréfan*, or sheriffs. One of their most important functions was the leading of the armed force of the county, a duty which often fell to their share during the period of the Danish invasions. The ealdorman, as such, held possession of certain lands attached to the office, and he was also entitled to a share of fines and other moneys levied for the king's use and passing through his hands. "Thus the position which his nobility, his power, and his wealth secured to the ealdorman was a brilliant one. In fact, the whole executive government may be considered as a great aristocratical association, of which the ealdormen were the members, and the king little more than the president. They were in nearly every respect his equals, and possessed the right of intermarriage with him; it was solely with their consent that he could be elected or appointed to the Crown, and by their support, co-operation, and alliance that he was maintained there. Without their concurrence and assent, their license and permission, he could not make, abrogate, or alter laws; they were the principal witan or counsellors, the leaders of the great gamót or national inquest, the guardians, upholders, and regulators of that aristocratical power of which he was the ultimate representative and head" (Kemble, Vol. II., p. 142).

Under the Danish kings the ealdorman fell into a subordinate position, the eorl or earl taking his place in the county. The ealdorman and the king were both surrounded by a number of followers called *thegns* or thanes, bound by close ties to their superior. The king's thanes were the higher in rank, and formed a kind of nobility by themselves. They possessed a certain quantity of land, smaller in amount than that of an ealdorman, and filled offices connected with the personal service of the king or with the administration of justice. According to Leppenberg they were in all respects the predecessors of the Norman barons. We frequently hear of a class of functionaries called *geréfan* or reeves, such as the *scir-geréfa* (shire-reeve or sheriff), the *port-geréfa* (port-reeve), the *tun-geréfa* (farm-reeve or bailiff; Scotch, *grieve*). These, of course, had different duties to perform, those of the shire-reeve being the most important. He presided at the county court along with the ealdorman and bishop, or alone in their absence; and had to carry out the decisions of the court, to levy fines, collect taxes, etc. In virtue of his office he had a portion of land allotted to him, hence called reeve-land. The shires were divided into hundreds and tithings, the former being equal to 10 of the latter. The tithing consisted of 10 heads of families, jointly responsible to the state for the good conduct of any member of their body. For the trial and settlement of minor causes there was a hundred court held once a month. The place of the modern Parliament was held by the *witena-gemót*, the representative council of the nation. Its members, who were not elected, comprised the æthelings or princes of the blood royal, the bishops and abbots, the ealdormen, the thanes, the sheriffs, etc.

Agriculture, including especially the raising of cattle, sheep, and swine, was the chief occupation of the Anglo-Saxons. Large tracts of the marshy land in the east of England were embanked and drained by them and brought

into cultivation. Gardens and orchards are frequently mentioned, and vineyards were common in the southern counties. The forests were extensive, and valuable both from the mast they produced for the swine and from the beasts of the chase which they harbored. Hunting was a favorite recreation among the higher ranks, both lay and clerical. Fishing was largely carried on, herrings and salmon being the principal fish caught. The whale fishery was also pursued, when the Anglo-Saxon vessels used to go as far as Iceland. The manufactures were naturally of small moment. Iron was made to some extent, and some cloth, and salt works were numerous. In embroidery and working in gold, however, the English were famous over the continent, and very elegant specimens of gold work have come down to our times. There was already a considerable trade at London, which was frequented by Normans, French, Flemings, and the merchants of the Hanse towns. The Anglo-Saxon forefathers were notorious for their excessive fondness for eating and drinking, and in this respect formed a strong contrast to the Normans who invaded the country. Ale, mead, and cider were the common beverages, wine being limited to the higher classes. Pork was a favorite article of food, and so were eels, which were kept and fattened in eel ponds and sometimes paid as rent. The houses were rude, ill-built structures, mostly of wood and without proper chimneys, but were often richly furnished and hung with fine tapestry. The dress of the Anglo-Saxons was loose and flowing, the materials being linen, woolen, and also silk; and their garments were often adorned with embroidery. The men looked upon the hair as one of their chief ornaments, and wore it long and flowing over their shoulders, while they also usually wore beards.

Christianity was introduced among the Anglo-Saxons in the end of the 6th century by St. Augustine, who was sent by Pope Gregory the Great and became the first Archbishop of Canterbury. Kent, then under King Ethelred, was the first place where it took root, and thence it soon spread over the rest of the country. It must, of course, be remembered that the Britons and Scots had already embraced Christianity, and missionaries from these labored in the conversion of the Anglo-Saxons. Monasteries were founded at an early period and became numerous. For a time the Anglo-Saxon Church maintained customs different in discipline from Rome, but uniformity was established in 670 by Theodore, the Archbishop of Canterbury. Many Anglo-Saxon ecclesiastics were distinguished for learning, but the Venerable Bede holds the first place. St. Boniface, the apostle of Christianity to the Germans, was an Anglo-Saxon.

An'glo-Sax'on Lan'guage, the oldest form of modern English, is the name generally given to the tongue spoken in Britain by its Teutonic settlers and invaders of the 5th and following centuries. The term Old English, though much to be preferred to Anglo-Saxon, has not yet met with general acceptance. The Anglo-Saxon belongs to the Teutonic branch of the Indo-European family of languages, which includes also the German, Dutch, Flemish, and Scandinavian tongues, and the oldest representative of which is the Gothic. The invading tribes spoke substantially the same language, though with marked differences of dialect, and this common tongue seems to lie midway between the Friesic and Old Saxon. The Angles settled in the north and east of Britain; the Saxons possessed themselves of most of the south and southwest; and the Jutes (numerically by far the smaller portion) established themselves in the southeast, chiefly in Kent and Surrey. Four distinct speech divisions arose: the two Anglian dialects, Northumbrian, spoken between the Humber and the Forth, and Mercian or Midland, spoken between the Thames and the Humber; the Saxon, spoken generally south of the Thames, except in Kent and Surrey; and Kentish, spoken in Kent and Surrey. The poems brought from the Continent were first written down in the Northumbrian dialect, and, indeed, most of the poetry composed in England seems to have been Northumbrian also. The Danish invasions destroyed the Northumbrian literature in great part; but during the West Saxon supremacy, in the great literary revival headed by King Alfred in the 9th century, the old poems were copied in the West Saxon dialect, and we know them only in that form.

The following are the chief features of the grammar of Anglo-Saxon, which was a synthetic language, in contradistinction to Modern English, which is analytic, or uninflected:

The Anglo-Saxon alphabet was the Latin with modifications made by English scribes. The letters F, G, R, and S, however, were quite unlike the usual forms. For two English sounds, W and TH, there were no convenient Latin signs, so two letters were adopted from the old Runic alphabet: Ƿ wēn, þ thorn; ð (edh) is a crossing of the Roman *d*. The most of the older editions of Anglo-Saxon texts have been printed with type made in imitation of the manuscript characters. In modern editions, the Roman characters are almost universally preferred, with the addition of ð, þ, and ȝ (representing G).

Pronunciation.— In general the vowels were pronounced as in modern German; the following table gives the approximate sounds:

a	as in	*a*sk (short).
ā	"	f*a*ther.
æ	"	m*a*n.
ǣ	"	th*e*re.
e ę	"	m*e*n.
ē	"	th*e*y.
i	"	h*i*t.
ī	"	s*ee*.
o ǫ	"	n*o*t
u	"	f*u*ll.
ū	"	r*u*le.
y	"	*i*t.
ȳ	"	s*ee*.

The diphthongs *ie*, *īe*, *ea*, *ēa*, *eo*, *ēo*, *io*, *īo*, receive the stress upon the first element.

The consonants *b*, *d*, *f*, *l*, *m*, *n*, *p*, *r*, *s*, *t*, *w*, *x*, *z*, were like mod. Eng. equivalents.

c had two sounds: as *c* in *cat*, and *k* in kink; *g* as in *go*, but in *ge*, *gi* it was pronounced as *y* in yet; *gea*, *gia* pronounced like *ya* in *yard*.

Phonology.— One of the commonest phenomena of Anglo-Saxon, as of German, is what is called *mutation*, or sometimes by the German name *umlaut*. M. in general is the influence exercised by a vowel on a vowel of the preceding syllable by which the first vowel is modified in the direction of the second, the result being a new vowel intermediate to the other two. The change may also be produced by a consonant in a succeeding syllable. For example the following changes are mutations:

A	to	Ę	as in	*mann* (man), plur. menn.
EA	to	IE	"	*eald* (old), *ieldra* (older).
U	to	Y	"	*burg* (city), plur. *byrig*.
Ō	to	Ē	"	*sōhte* (sought), *sēcan* (to seek).
ĒO	to	ĪE	"	*steor* (rudder), *stīeran* (steer).

Gradation (German *ablaut*) is the name given to a distinct vowel variation by which a root may appear in two or more forms even in the inflection of a single word: for example, *begin, began, begun.* Modern English *write, wrote, written* corresponds stem for stem to Anglo-Saxon *wrītan, wrāt, writen*, Anglo-Saxon ī and ā having become Modern English *ai* (written ī), and ō, short *i*, being preserved. Gradation is important because it is the characteristic means of distinguishing tense in the Anglo-Saxon strong verb.

Grammar.— There are three genders in Anglo-Saxon, masculine, feminine, and neuter, but they are grammatical rather than natural in their dependence; for example *wīf* (wife) is neuter; *sunne* (sun) is feminine; *mona* (moon) is masculine. Of most words the gender can only be learned by practice. There are four cases: nominative, genitive, dative, and accusative. The accusative and nominative are the same in all plurals, in the singular of all neuter nouns, and of all strong masculines. The dative plural of nearly all nouns ends in -*um*.

There are two schemes of noun inflection: the strong (or vowel) declension, and the weak (or neuter) declension. Weak nouns form their inflection with *n;* all others are strong. The following shows typical examples of each:

Strong Declension.

Masc.	Fem.	Neut.
Singular.	sing.	sing.
N. A. stān *(stone).*	N. giefu *(gift).*	N. A. scip *(ship).*
G. stānes.	G. D. A. giefe.	G. scipes.
D. stāne.		D. scipe.
Plural.	Plural.	Plural.
N. A. stānas.	N. A. giefa.	N. A. scipu.
G. stāna.	G. giefena.	G. scipa.
D. stānum.	D. giefum.	D. scipum.

Weak Declension.

Masc.	Fem.	Neut.
Singular.	Singular.	Singular.
N. nama *(name).*	sunne *(sun).*	N. A. ēage *(eye).*
G. D. A. naman.	sunnan.	G. D. ēagan.
Plural.	Plural.	Plural.
N. A. naman.	sunnan.	N. A. ēagan.
G. namena.	sunnena.	G. ēagena.
G. namum.	sunnum.	D. ēagum.

Adjectives also have three genders, the same cases as nouns, though with somewhat different endings, and a strong and a weak inflection. In the masculine and neuter singular they have an instrumental case for which in the feminine and plural and in the Weak inflection the dative is used. The Strong and Weak inflections are employed according as the adjectives are respectively Indefinite or Definite. The weak forms are used when the adjective is preceded by a demonstrative; the comparatives always, and superlatives usually, follow this declension, which agrees throughout with the weak declension of nouns, except that the genitive plural often ends in *-ra.* The strong declension is used when none of the conditions for the use of the weak declension are present, and with few exceptions it agrees with the strong declension of nouns.

The pronouns are peculiar in that they have a dual number: for example, N. *wit* (we two), N. git (*ye two*): Gen. *uncer, incer;* Dat. and Acc. *unc, inc,* respectively.

The verb had a single inflected voice, two tenses, two complete modes, besides an imperative in the present tense only; two numbers, three verbal nouns, the infinitive, the present, and the past participle. The verbs are divided into two classes: (1) those which form their principal parts with a variation of the root vowel (strong verbs), and (2) those which form the preterite and the past participle by the addition of *d* (-ode, -ede, -de) to the root syllable (weak verbs). The following is the conjugation of the strong verb *bindau* (bind), and shows the endings common to all verbs:

		Indicative.		Subjunctive.
Pres. sing.	1.	bind-e.		bind-e.
	2.	bind-est, bintst.		bind-e.
	3.	bind-e*þ*, bint.		bind-e.
plur.		bind-a*þ*.		bind-en.
Pret. sing.	1.	band.		bund-e.
	2.	bund-e.		bund-e.
	3.	band.		bund-e.
plur.		bund-on.		bund-en.
Imper. sing.		bind.	*Infin.*	bind-an.
plur.		bind-a*þ*.		
Partic. pres.		bind-ende;		
pret.		ge-bund-en.		
		Gerund. tō bind-enne.		

For the future tense the present is used, and periphrastic tenses are sometimes formed as in Modern English by *haebbe* (have) and *haefde* (had) with the past participles. The passive is formed with *wesan* (to be) or *weorþan* (become) with the past participle. These forms are extremely vague, but *wesan* seems to indicate a state, *weorþan* an action. The subjunctive is used to express wish, conditions, doubt, etc.

The order of words in Anglo-Saxon strongly resembles that of German, the verb coming before its nominative when the sentence is headed by an adverb or adverbial group, or when the object or predicate is put at the head of the sentence. In principal sentences there is a tendency to put the verb at the end, or at least to bring it near the end.

BIBLIOGRAPHY.— *General.*— O. F. Emerson's 'History of the English Language' (1897), and T. N. Toller's 'Outlines of the History of the English Language' (1900) will be found useful. For exhaustive bibliography of Anglo-Saxon language and literature see Körting's 'Grundriss der Geschichte der Englischen Litteratur) (3d ed. 1899), and R. P. Wuelker's 'Grundriss zur Geschichte der Angelsächsischen Litteratur' (1885).

Grammars.—'Angelsächsischer Grammatik von E. Sievers' (1886), English translation by A. S. Cook (2d ed. 1899); P. J. Cosign, 'Altwestsächsische Grammatik' (1883–8); F. A. March, 'Comparative Grammar of the Anglo-Saxon Language' (1870). There are excellent grammatical introductions to the 'Anglo-Saxon Readers' of H. Sweet (7th ed. 1897), and J. W. Bright (3d ed. 1894). Grimm's 'Deutsche Grammatik' (1840), E. Maetzner's 'English Grammatik' (3d vol., 3d ed. 1880), are indispensable for the advanced student.

Dictionaries.— Bosworth's 'Dictionary of the Anglo-Saxon Language,' edited and enlarged by T. N. Toller (1882–1900); H. Sweet's 'Student's Dictionary of Anglo-Saxon' (1897); J. R. C. Hall's 'Concise Anglo-Saxon Dictionary' (1894); and Vols. III. and IV. of Grein's invaluable 'Bibliothek der Angelsächsischen Poesie' (1861-4).

W. N. C. CARLTON,
Librarian Trinity College.

An'glo-Sax'on Literature, the term given to the literary remains of the English people from their earliest settlement in Britain to about 1100 A.D. It possesses a peculiar interest and importance because it is the oldest of the vernacular literatures of modern Europe. Its beginning, so far as it can be treated chronologically, lies between 658–680, the years of the abbacy of Hild at Whitby. Its oldest fragments give us a close view of the social conditions of the heathen Germanic age. Poetry antedates prose and was first cultivated in the north, in the Anglian kingdom of Northumbria more particularly. Later, when Northumbria lost her supremacy, and the kingdom of Wessex under Alfred rose to political leadership, the literary pre-eminence also was transferred to the latter. There are therefore two periods of Anglo-Saxon literature: the Anglian and the Saxon. The first produced only poetry; the second was largely a period of recasting and imitation, but possesses an independent interest in that it raised Anglo-Saxon prose to its highest point of efficiency as a literary vehicle. Practically all the poetry has come down to us only in its West Saxon dress, the Northumbrian originals being almost wholly lost.

Anglo-Saxon Versification.— Anglo-Saxon poetry is composed in a kind of blank verse, in unrimed, ungrouped, but alliterative lines. Every line consists of two parts, or half-lines, separated by a cæsura and united by alliteration; for example:

"Mē *s*ęndon tō thē ‖ *s*æmęn *s*nelle,
hēton the *s*ęcgan ‖ thæt thu most *s*ęndan **rathe**
*b*eagas with ge*b*eorge. ‖ and ēow *b*ętere is
thæt *g*e thisne gārrǣs ‖ mid **gafole** forgyldon,
thonne wē swā *h*earde ‖ *h*ilde dǣlon.

Maldon, ll. 29-33.

1. "Me have sent to thee — the seamen swift:
2. They bade to thee say — that thou must quickly send
3. Bracelets for safety; — and to you it better is
4. That ye the spear-rush — with tribute buy off,
5. Than that we so hard — a battle shall deal out."

Every half-line has two rhythmical accents (stresses), and two rhythmical measures (feet); it is a structural unit having a scansion of its own independent of the complementary half-line. In its simplest form the measure (foot) consists of two parts, an accented and an unaccented. Alliteration,— that is, the riming of the initial sounds of words or syllables, is employed to unite the two half-lines into the larger rhythmical unit of the complete line. It is confined to rhythmically accented syllables. Alliterating syllables have the same initial consonant (*st, sp, sc* alliterate each with itself only), or they have an initial vowel sound, any vowel or diphthong whatever alliterating with itself or with any other vowel sound. The rhythmical accentuation coincides in general with the accentuation required by the sense. The four chief stresses of a complete line therefore fall upon the four most significant words or syllables of that line. *Cf.* Siever's 'Altgermanische Metrik' (Halle 1893), and his article in Paul's 'Grundriss der Germanischen Philologie,' Vol. II.

Poetry.— The epic of 'Beowulf,' the oldest extant heroic poem in any Germanic tongue, celebrates the deeds of a Swedish hero of that name, particularly his victory over a man-eating monster called Grendel, and his final victory, which costs him his life, over a fiery dragon. The material is mythical and heathen, and the scene is laid in Denmark and southwest Sweden. Discussion as to its origin, date, and composition has become the "Homeric question" of Anglo-Saxon scholars. In many respects the most satisfactory theory regarding it is still that of Benjamin Thorpe: "From the allusions to Christianity I do not hesitate to regard it as a Christian paraphrase of a heathen saga, and those allusions as interpolations of the paraphrast, whom I conceive to have been a native of England of Scandinavian parentage." It is unquestionably a genuine production of the time when the old heathen tales still had their traditional interest, even though the Saxons had become thoroughly converted to Christianity. It was edited at an Anglian court, and the text took substantially the shape in which it has come down to us about the beginning of the 8th century. The poem is preserved in but one manuscript (Cott. Vitt. A. XV.) in the British Museum, which, according to palæographers, dates from the 10th century.

Cædmon, a Northumbrian herdsman of the 7th century, is the reputed author of some metrical paraphrases of the Old Testament. The so-called "sacred epics" include paraphrases of portion of Genesis, Exodus, and Daniel. In the manuscript volume containing them are fragments of three other poems relating to (1) the fall of the angels, (2) Christ's descent into hell, and (3) his temptation in the wilderness. The Exodus is the work of a true poet, but modern criticism has shown that the various portions of the "Cædmon poetry" exhibit differences of style inconsistent with the supposition of a common authorship. The most probable conclusion seems to be that Cædmon's rude Northumbrian verses were regarded by the writers of King Alfred's age as raw material which they worked over with unequal degrees of poetic skill. The poems are preserved in a 10th century manuscript in the Bodleian Library. Printed editions are: Junius' (1655); Thorpe's (London 1832); Boutewek's (2 vols. Gutersloh, 1849–54); and in the Grein-Wülker 'Bibliothek der Angelsächsischen Poesie.'

Cynewulf, like Cædmon, was a Northumbrian, but we have no certain knowledge of the time or place at which he lived. The certain works of his composition are the 'Legend of St. Guthlac,' 'Legend of St. Juliana,' 'Christ,' 'Andreas,' 'Elene,' the 'Fortunes of the Twelve Apostles,' and some 'Riddles.' Kemble first discovered that the runes in the 'Riddles,' 'Christ,' 'Juliana,' and 'Elene' gave the name Cynewulf, and thus recognized the name of their author. The Cynewulf poems show us the artist with whom Christian ideas have become native and spontaneous, and who disposes like a master of the rich legacy of epic diction and perception. Shorter poems and fragments whose material dates from the earliest times, and careful study of which throws much light upon Anglo-Saxon manners and cast of thought, are: 'Widsith' (the far-traveler), 'Lament of Deor,' 'The Scop' (Gleeman), 'The Wanderer,' 'The Departed Soul's Address to the Body,' and 'Waldhere.' The 'Wanderer' is thoroughly representative of the lyrics produced during the Anglian period. Of West Saxon composition and much later date are the two fine battle-pieces inserted in the Anglo-Saxon chronicle: 'The Battle of Brunanburh'

and 'The Battle of Maldon.' In the latter the relation between a lord and his men is seen under the severest test; the former throbs with patristic enthusiasm.

Prose.— With the accession of Egberht (800) Wessex began to take rank as the leading power in Britain. King Alfred (871–901) pushed this movement forward, and through his successive repulses of the Danish invasion made it an established fact. His services to literature and education were no less important. Knowledge of Latin having apparently died out in England, Alfred himself began translating important and helpful works into his native tongue, and unceasingly encouraged the learned men of his court and clergy to similar efforts. He revived interest in keeping the national annals; and the 'Anglo-Saxon Chronicle,' in the form in which it has come down to us, was the result. For the years of his reign it is of great value historically. (For his translations, etc., see ALFRED.) He was, in truth, the first to give his people a national prose literature.

Besides the compilation of laws made by Alfred there is extant a large body of legal documents such as grants of land, purchases, memorials, wills, royal writs, etc., extending from the 7th to the 12th century. At first all were entirely in Latin; then a few Anglo-Saxon words crept in, and then the native element goes on increasing until we have entire documents in Saxon. This literature fills six volumes of Kemble's 'Codex Diplomaticus.'

The religious prose forms an extensive portion of Anglo-Saxon literature, comprising translations of parts of the Old Testament and of the Gospels in the New, large collections of homilies, and almost all the work of Ælfric (q.v.) and Wulfstan. The period of literary productivity initiated by Ælfric was practical and popular rather than scholarly. It produced chiefly homilies, lives of the saints, translations, and service books. But all had a direct effect upon the people and language, and the mere existence of this literature proves that the English clergy were neither so ignorant nor so idle as sometimes represented.

Other writings deserving mention as showing the variety of the literature are: the translation of the late Greek romance, 'Apollonius of Tyre' in flowing English by a skilful pen; an English 'Herbarium' of the first half of the 11th century, which analyzes the medicinal uses of plants, and another work treating similarly of animals. 'The Læce Boc' (Leech Book) is a remarkable and comprehensive collection of medical prescriptions and recipes for the most diverse diseases, whose causes are also touched upon. ('Leechdoms, Wortcunning, and Starcraft of Early England.' Ed. by O. Cockayne, 2 vols. Lond. 1864–6.)

Bibliography.— For elaborate surveys of the literature relating to Anglo-Saxon language and literature see Wülker, 'Grundriss zur Geschichte der Angelsächsischen Litteratur' (1885); Korting, 'Grundriss der Geschichte der Englischen Litteratur' (3d ed. 1899). For histories of the literature see H. Morley, 'English Writers,' Vols. I., II.; Ten Brink, 'Early English Literature,' translation by Kennedy (1883); Earle, 'Anglo-Saxon Literature' (1884); Brooke, 'History of Early English Literature' (1899).

W. N. C. CARLTON,
Librarian Trinity College.

Angora, or **Engour** (the ancient ANCYRA), a town of Asiatic Turkey; 215 miles east of Constantinople, with which there is now railway communication. It has ruinous walls, and there are some remains of Byzantine architecture belonging to the ancient city, and a few relics of earlier times, both Greek and Roman. Among the latter are the remnants of the Monumentum Acyranum, raised in honor of the Emperor Augustus, who much embellished the ancient city. Angora is celebrated for the long-haired goats bred in its vicinity called by the Arabs the chamal goat, meaning "silky or soft." Goat's hair forms an important export; other exports being goats' skins, dyestuffs, principally madder, and yellow berries; mastic, tragacanth, and other gums; also honey and wax. British manufactures are imported to some extent. Estimated pop. 35,000.

Ango'ra Cat. See CAT.

Ango'ra Goat. See GOAT.

Anhy'drid, ăn-hī'-drĭd (from a Greek word signifying "without water"), an oxid which produces an acid when it combines with water, or which is obtained by removing water from an acid. Oxids which yield salts by combining directly with other more basic oxids may also be classed as anhydrids. The oxids of most of the non-metallic elements are anhydrids.

Anhydrite, a mineral having the composition of calcium sulphate, $CaSO_4$, and differing from gypsum in its lack of water. In its common white, massive form it much resembles the snowy-white gypsum (q.v.), but is readily distinguished by its superior hardness, 3 to 3.5. Anhydrite also occurs in orthorhombic crystals and in cleavable-lamellar and fibrous masses. Its colors are very varied, white or gray being the most common, but blue and even brick-red not being uncommon. It is brittle, breaking with an uneven or splintery fracture, or when crystallized, cleaving with ease into rectangular chips. Its lustre is also very varied, the crystals appearing pearly, greasy or vitreous according to the faces examined.

Ani, ä'ne, a lustrous blackbird (*Crotophaga ani*), of Florida, the West Indies, and tropical America, which is one of the cuckoo family.

Aniline, an'i-lin, an organic substance, discovered by Unverdorben in 1826, but of no commercial importance until W. H. Perkin prepared a purple dye from it in 1856. Since that time aniline and its derivatives have been used in great quantities for the preparation of the aniline dyes, of which a great number are now known. (See COAL-TAR COLORS.) Aniline, in its chemical aspect, is an amine of the organic radical "phenyl," C_6H_5, with the formula $C_6H_5NH_2$. (See AMINE.) It may be prepared from benzene, C_6H_6, by the action of nitric acid and (subsequently) a reducing agent. Thus the effect of nitric acid upon benzene is represented by the following equation:

$$C_6H_6 + HNO_3 = C_6H_5.NO_2 + H_2O.$$

The compound $C_6H_5.NO_2$, known as nitrobenzene, is a yellow liquid, boiling at 400° F. By the action of nascent hydrogen (which may be conveniently generated by adding acetic acid

and iron filings) nitro-benzene is converted into aniline, hydrogen being substituted for the oxygen in the group NO_2. The equation is:

$$C_6H_5.NO_2 + 6H = C_6H_5.NH_2 + 2H_2O.$$

In the commercial manufacture of aniline the nascent hydrogen is generated by the action of hydrochloric acid upon scrapings from soft iron castings. It may be noted as an interesting fact that lathe chips or borings from wrought iron or from hard castings do not answer the purpose satisfactorily. Pure aniline is a colorless liquid, freezing at 18° F., and boiling at about 363°. Its specific gravity is about 1.024 at ordinary temperatures. It unites with many other substances to form compounds, and is expelled from its salts by potash, soda, and lime. Aniline does not mix with water, but can dissolve about five per cent of its own bulk of water. See ROSANILINE.

An'iline Poisoning. The use of the anilines, and particularly of the new synthetic drugs derived from this product, has become so universal that many instances of poisoning, both acute and chronic, are observed. In acute aniline poisoning the chief effects are on the blood. It prevents the oxidation of hæmoglobin in the red blood-cells, forms methemoglobin, causes the destruction of red blood-cells (hæmolysis), and thus results in death. The chief symptoms are headache, vertigo, weakness, and stumbling walk, blue color of defective blood oxidation (cyanosis), disturbances of respiration, increase of urine, which is frequently colored reddish to dark brown from the broken-down blood-cells, depression of temperature, chills, dilated pupils, and death from asphyxia. In non-fatal cases recovery may be much protracted. Treatment consists in withdrawal of all of the poison, washing the stomach, fresh air, artificial respiration, and infusion of normal salt solution. The aniline derivations mostly used are acetanilid (antifebrin), phenacetin, exalgen, lactophenin, methacetin, malakin, phenocoll, citrophen, apolysin, cosaprin, malarin, etc. Chronic aniline poisoning, found chiefly among workers in color factories, is of much the same character, but the symptoms develop slowly. There are skin symptoms, urinary changes, and various nervous attacks, with headache, tremors, changes in sensation, anesthesiæ, etc. The treatment should involve the ventilation of the factories, thus getting rid of the color-dust floating in the moisture of the rooms.

An'imal, the word animal being derived from *anima*, breath, soul, suggests the distinction popularly accorded to animals as contrasted with plants. Linné said that plants grow and live, but that animals grow, live, and feel. As will be seen below, however, animals do not fundamentally and in their simplest forms differ from the simplest plants, as both are constituted of protoplasm, which is equally contractile in both kingdoms, and thus we now recognize the fact that nature is divided into the inorganic world and the organic, and we are coming more and more to speak of living beings as organisms, since plants and animals have so much in common. All organized beings agree in being formed of protoplasm, "the physical basis of life."

Differences between Plants and Animals.— It is difficult, when we consider the simplest forms of either kingdom, to define what an animal is as distinguished from a plant, for it is impossible to draw hard and fast lines between them. In defining the limits between the animal and vegetable kingdoms our ordinary conceptions of what a plant or an animal is will be of little use in dealing with the lowest forms of either kingdom. A horse, fish, or worm differs from an elm-tree, a lily, or a fern in having organs of sight, of hearing, of smell, of locomotion, and special organs of digestion, circulation, and respiration, but these plants also take in and absorb food, have a circulation of sap, respire through their leaves, and some plants are mechanically sensitive, while others are endowed with motion,— certain low plants, such as diatoms, etc., having this power. In plants the assimilation of food goes on all over the organism, the transfer of the sap is not confined to any one portion or set of organs as such. It is always easy to distinguish one of the higher plants from one of the higher animals. But when we descend to animals like the sea-anemones and coral-polyps, called by Wotton zoophytes, from their general resemblance to flowers, so striking is the external similarity between the two kinds of organisms that the early observers regarded them as "animal flowers;" and in consequence of the confused notions originally held in regard to them the term zoophytes has been perpetuated in works of systematic zoology. Even at the present day the compound hydroids, such as the *Sertularia*, are gathered and pressed as sea-mosses by many persons who are unobservant of their peculiarities and unaware of the complicated anatomy of the little animals filling the different leaf-like cells. Sponges until a very late day were regarded by our leading zoologists as plants. The most accomplished naturalists, however, find it impossible to separate by any definite lines the lowest animals and plants. So-called plants, as *Bacterium* or *Bacillus* and their allies, and so-called animals, as *Protamœba*, or certain monads, which are simple specks of protoplasm without genuine organs, may be referred to either kingdom. Indeed, a number of naturalists, notably Haeckel, relegate to a neutral kingdom (the *Protista*, q.v.), certain lowest plants and animals. Even the germs (zoospores) of monads like *Uvella* and those of other flagellate infusoria may be mistaken for the spores of plants; indeed, the active flagellated spores of plants were described as infusoria by Ehrenberg; and there are certain so-called flagellate infusoria so much like low plants (such as the red-snow or *Protococcus*), and the slime molds (*Myxomycetes*) in the form, deportment, mode of reproduction, and appearance of the spores, that even now it is possible that certain organisms placed among them are plants. It is only by a study of the connecting links between these lowest organisms, leading up to what are undoubted animals or plants, that we are enabled to refer these beings to their proper kingdom.

As a rule, plants have no special organs of digestion or circulation and nothing approaching to a nervous system. They differ from animals in their metabolic processes. Most plants absorb inorganic food, such as carbonic

acid gas, water, nitrate of ammonia, and some phosphates, silica, etc.; all of these substances being taken up in minute quantities. Low fungi live on dead animal matter and promote the process of putrefaction and decay, but the food of these organisms is inorganic particles. The slime molds, however, envelop the plant or low animals much as an amœba throws itself around some living plant and absorbs its protoplasm; but *Myxomycetes,* in their manner of taking food, are an exception to other molds and are now regarded as animals. The lowest animals swallow other living animals whole or in pieces; certain forms, like *Amœba* (q.v.), bore into minute algæ and absorb their protoplasm; others engulf silicious-shelled plants (diatoms), absorbing their protoplasm. No animal swallows silica, lime, ammonia, or any of the phosphates as food. On the other hand, plants manufacture or produce from inorganic matter starch, sugar, and nitrogenous substances which constitute the food of animals. During assimilation plants absorb carbonic acid and in sunlight exhale oxygen; during growth and work they, like animals, consume oxygen and exhale carbonic acid.

Animals move and have special organs of locomotion: few plants move, though some climb, and minute forms have thread-like processes or vibratile lashes (*cilia*) resembling the flagella of monads, and flowers open and shut; but these motions of the higher plants are purely mechanical and are not performed by special organs controlled by nerves. The mode of reproduction of plants and animals, however, is fundamentally identical, and in this respect the two kingdoms unite more closely than in any other. Plants also, like animals, are formed of cells, the latter in the higher forms combined into tissues.

Physiological Distinctions and Resemblances. —As has been said, the bodies of the lowest plants and animals are plainly enough made up of protoplasm. The irritability, contractibility, and metabolism of a plant-cell or a living, free unicellular plant do not differ from those of a unicellular animal (*Protozoon*) of the same morphological grade. The movements of the lowest algæ, the sensitiveness of the leaves of the mimosa-tree, of the sun-dew and other insectivorous plants, are due to the same primary cause as the movements of animals of all grades, as the power of lifting one's arm is fundamentally due to the contractibility of the protoplasm forming the cells of the muscles.

Also, as has been said, the differences in metabolism are not fundamental, those molds which do not contain chlorophyll, and bacteria, performing the same metabolic functions as regards carbon dioxid as animals. Also the power of forming cellulose in plants is not peculiar to them, as this substance is found in several types of animals, as rhizopods and *Tunicata.* Animals are also subject to the same general tropisms as plants; they are geotropic, heliotropic, thermotropic, hydrotropic, chemotropic, etc. (See TROPISMS.) To a much greater extent than formerly supposed even insects so highly developed as ants are subject to the influences of the primary factors of growth, morphogenesis, and of the conduct of life, and the instincts of animals in general are more dependent on these agents, on external stimuli, than was previously thought to be the case.

Plants Fixed Organisms; Animals as a Rule Free-moving.— While the lowest plants (*Protophytes*) are, as entire organisms, often motile, free-swimming, closely resembling monads, the higher or more specialized forms, comprising the great majority of the vegetable world, are fixed, and have always remained so. It is this fixed condition of life which, so to speak, has held the plant world in an iron grasp and kept it within its natural limits. On the other hand animals as a rule are active, free to move, restless. Whenever animals, though born as free-swimming germs or larvæ, are constrained by change of circumstances to become attached or fixed to the sea-bottom or solid objects, they degenerate and become more and more subject to the influence during growth of those cosmic and physical forces, such as gravity, light, air, currents of water, etc., which determine the shapes and morphology of plants. Fixed animals, like the zoophytes or the polyps, sea-anemones, all sponges, cœlenterates, *Polyzoa,* etc., which lead a purely vegetable life, tend to assume plant-like shapes. Even the echinoderms, as the fixed crinoids, are plant-like, hence their name, sea-lilies. It is freedom of motion, greater activity, which led to the vastly more complex and higher types of life in animals, to the development of a nervous system, and to the origin of mind and intelligence.

Plants Not the Primitive Basis of Animal Life.— As the lowest plants and animals are scarcely distinguishable, it is probable that plants and animals first appeared contemporaneously; and while plants are generally said to form the basis of animal life, this is only partially true; a large number of fungi are dependent on decaying animal matter; and most of the *Protozoa* live on animal food, as do a large proportion of the higher animals. The two kingdoms supplement each other, are mutually dependent, and probably appeared simultaneously in the beginning of things. It should be observed, however, that the animal kingdom greatly overtops the vegetable kingdom, culminating in man.

The Animal Series Tree-like.— It was an old idea that the living world forms a regular or linear series, more or less regularly graduated. The older naturalists spoke of "the scale of being," "the chain of being." Lamarck was the first to show that such a series does not exist. He compared the animal kingdom to a tree, "a branching series, irregularly graduated," and he recognized that there were breaks, missing branches "owing to the extinction of some species." He explains that the animal kingdom begins by at least two special branches, then ending in branchlets. He thus broke entirely away from the idea of a continuous ascending series imagined by Bonnet and others in the 18th century. While therefore there is, speaking in general terms, a progressive series of animal forms from monad to man, the animal kingdom more truly resembles a tree which began to send out branches very near its base; many of the branches being inextricably interlaced, while others — representing the degenerate types, as sponges, stationary or fixed groups, such as polyps, barnacles, many parasites, etc.— are

downward-bent branches. As a whole, however, the branches show a tendency to ascend and spread out more or less upward. See ZOOLOGY.

An'imal Al'kaloids. Ptomains (q.v.) was the name originally given to a large class of products resulting from the putrefactive process occurring in animal substances. These possessed many of the chemical reactions of the vegetable alkaloids and have been termed animal alkaloids. Similar products formed in the human body, as the result of normal metabolism chiefly of lecithin, or proteids, are termed leucomains. Many of these ptomains and leucomains are highly poisonous toxins. See ALKALOIDS; METABOLISM; PTOMAINS; TOXICOLOGY.

Animal Charcoal. See CHARCOAL.

An'imal Chem'istry, the department of organic chemistry which investigates the composition of the fluids and the solids of animals, and the chemical action that takes place in animal bodies. There are four elements, sometimes distinctively named organic elements, which are invariably found in living bodies, namely, carbon, hydrogen, oxygen, and nitrogen. To these may be added, as frequent constituents of the human body, sulphur, phosphorus, lime, sodium, potassium, chlorin, and iron. The four organic elements are found in all the fluids and solids of the body. Sulphur occurs in blood and in many of the secretions. Phosphorus is also common, being found in nerves, in the teeth, and in fluids. Chlorin occurs almost universally throughout the body; lime is found in bone, in the teeth, and in the secretions; iron occurs in the blood, in urine, and in bile; and sodium, like chlorin, is of almost universal occurrence. Potassium occurs in muscles, in nerves, and in the blood corpuscles. Minute quantities of copper, silicon, manganese, lead, and lithium are also found in the human body. The compounds formed in the human organisms are divisible into the organic and inorganic. The most frequent of the latter is water, of which two thirds (by weight) of the body are composed. The organic compounds may, like the foods from which they are formed, be divided into the nitrogenous and non-nitrogenous. Of the former the chief are albumen (found in blood, lymph, and chyle), casein (found in milk), myosin (in muscle), gelatin (obtained from bone), and others. The non-nitrogenous compounds are represented by organic acids, such as formic, acetic, butyric, stearic, etc.; by animal starches, sugars; by fats and oils, as stearin and olein, and by alcohols (two compounds, cholesterin and glycerin).

An'imal Col'ors. See COCHINEAL; KERMES; PURPLE SHELLS.

An'imal E'lectric'ity, electricity which certain species of animals, particularly those inhabiting the water, have the power of producing. The amount which they can produce varies with different animals. The electric eel or torpedo can give a severe shock. Contact between the nerve and muscle of a frog will produce a feeble current of electricity.

An'imal Flow'er, a term applied to sea anemones or similar polyps on account of the resemblance which their expanded tentacles bear to flower petals.

An'imal Heat, nearly all animals possess a heat-regulating mechanism by which they maintain a temperature necessary for the continuance of life processes. In many cold-blooded animals this sustains a temperature only slightly above that of the surrounding media, and thus in winter they relapse into a torpid state. Some few, however,— bees being an example,— have a higher temperature and are not torpid. In warm-blooded animals, especially those high in the evolutionary scale, a high constant temperature is usually sustained. Some warm-blooded animals occupy an intermediary position. In summer the temperature is high and constant, in winter they hibernate, and the temperature is low and dependent upon that of the surrounding medium. Some cold-blooded animals living in the tropics may really show very high degrees of temperature, thus the terms warm-blooded and cold-blooded are relative only. The mean average temperature in man is 36.97° C. (98.4° F.) in the mouth, 36.98° C. (98.5° F.) in the axilla, and 37.2° C. (99° F.) in the rectum. There are slight daily variations, the lowest temperature usually being between midnight and early morning during sleep. Certain warm-blooded animals show interesting average temperatures. Thus, the horse is 99–100° F., ox 100–101° F., cow 101–102° F., sheep 104–105° F., dog 100–101° F., cat 101° F., pig 101–103° F., rabbit 101–107° F., rhesus monkey 101° F., duckbill platypus 76° F., hen 106–109° F., duck 107–110° F., sparrow 110° F. In cold-blooded animals the temperature, as has been noted, varies widely. The study of the temperature of bees is of much interest in this connection.

Several conditions modify the regulation of the animal heat: day and night, age, muscular work, sleep, sex, race, pregnancy, idiosyncrasies, surrounding temperature, season of the year, baths, and certain drugs, all have a distinct influence on the heat regulatory apparatus. The variations in temperature in man compatible with life are wide; a range of less than 2° F. is normal, but variations from 75° to 112° F. have been recorded and the patients recovered. Temperatures below 80° F. and above 106° F. are dangerous.

The chief sources of animal heat are the chemical processes of the body and they are dependent on the food supply. Every kind of food has its definite percentage of heat-producing elements measured in units, or calories. Thus 1 gm. (15 grains) of the white of egg has 4,896 calories; the same amount of cow's milk 5,733 calories, of fat 9,600 calories, etc. These are purely physical values, but they have their physiological equivalents. The chief sources of heat production in the human body are the muscles, the heart contraction being a very important one, and the glands (intestines, liver, etc.). Loss of heat takes place through the skin by radiation and conduction, by evaporation, from the respiration, and from the dejecta.

Regulation of these many factors is in the province of the nervous system. The vasomotor system controls the heat loss by regulating the amount of blood in the deep and superficial portions of the body, the respiratory centre regulates the amount of respiration, and the cerebral cortex regulates the amount of muscular activity that is the main source of the heat production. See FEVER.

An'imal Mag'netism, a science or art, so called because it was once believed that it taught the method of producing on persons of susceptible organization effects somewhat similar to those which a magnet exerts upon iron. Paracelsus (b. 1493) maintained that the human body was endowed with a double magnetism; on the one side attracting to itself the planets, whence comes wisdom and the senses, on the other side attracting the elements and nourished by their disintegration; that the attractive virtue resembles that of the magnet, and that healthy persons attract the enfeebled magnetism of the sick. Many writers of the 16th century sought to explain all natural phenomena by this principle.

Mesmer (b. 1734) drew largely from these sources in preparing his thesis on 'The Influence of the Planets in the Cure of Diseases.' Believing in a subtle fluid through which the heavenly bodies acted upon living beings, he called this animal magnetism, because of certain properties he believed it to possess in common with the magnet. The sick were said to have been cured by the influence of magnets manipulated by the Jesuit Father Hell, in 1774, in Vienna. Mesmer began the use of the magnet, but soon gave it up, restricting himself to passes of the hand over or near the body of the patient, or to placing the hand in contact with the body in the hypochondriac region, or the lower part of the abdomen. He declared animal magnetism to be distinct from the magnet. His doctrine obtained notice for a time. As the patients increased in number it became impossible for him to treat each one separately, and he devised a trough about which 30 persons or more could be magnetized at once. This *baquet* or trough consisted of a circular oaken case about one foot deep, surrounded by curtains through which a subdued light was permitted to penetrate. In the bottom of the case was a layer of powdered glass and iron filings; on this lay bottles arranged with their necks all pointing toward the centre; a second lot of bottles were arranged with their necks in the opposite direction: the trough might be filled with water or remain dry. Through the lid of the trough jointed iron rods projected and branched in various directions: these were held by the patients. Should the numbers be very large a second row of patients might be connected with the first row by cords about their bodies; and a third row could be arranged by joining hands with the second row. During an interval of silence a melodious air was heard from an adjoining room. Soon, influenced by the magnetic effluvia issuing from the *baquet*, curious phenomena were produced. Some of the persons under treatment seemed to experience no change in their condition; others coughed, experienced pain, and sweat; others suffered from convulsions of greater or less violence which lasted for hours. These convulsions were preceded or followed by a state of languor and depression. Such a state of convulsions, when produced in one person, was quickly followed by similar conditions in others. The movements of the limbs and body, the twitchings of the hypochondriac and epigastric regions are manifest signs of hysteria and may be referred to the nervous antecedents of the group of persons and to the influence of imitation and suggestion. Mesmer, in a coat of lilac silk, walked around among the crowd, touching the diseased parts of the bodies of the patients with a long iron rod which he carried in his hand.

His cures in Paris attracted so much attention that in 1784 a commission was appointed by the government to examine into the matter. The commission consisted of members of the Faculty of Medicine and of the Academy of Sciences.

A second commission from the Royal Society of Medicine was charged to make a distinct report on the same subject. Mesmer and his assistants desired that the cures that had been effected be accepted as proof of the existence of animal magnetism. The commissioners, however, placed themselves under treatment once a week; they experienced no convulsive movements or other effects that appeared to be shown in some patients. They found that patients unaware of the fact that they were being magnetized experienced none of its effects, and that patients who were told they were being magnetized experienced the symptoms, though the magnetizer was not near them.

The conclusion of the report of the commissioners is as follows: "The commissioners have ascertained that the animal magnetic fluid is not perceptible by any of the senses; that it has no action, either on themselves or on the patients subjected to it. . . . Finally, they have demonstrated by decisive experiments that imagination apart from magnetism produces convulsions, and that magnetism without imagination produces nothing. They have come to the unanimous conclusion with respect to the existence and utility of magnetism that there is nothing to prove the existence of the animal magnetic fluid; that this fluid, since it is non-existent, has no beneficial effect; that the violent effects observed in patients under public treatment are due to contact, to the excitement of the imagination, and to the mechanical imitation which involuntarily impels us to repeat that which strikes our senses."

The existence of a magnetic fluid is yet to be proved. All of the phenomena which Mesmer produced and attempted to explain by the existence of such a fluid are now explained by the principle of hypnotic suggestion. See HYPNOTISM. Consult Binet and Fere, 'Animal Magnetism' (1888); Albert Moll, 'Hypnotism' (1898).

An'imal Psychol'ogy is the science which investigates the phenomena of the life of animals lower than man with reference to their mental endowment. It seeks to know the animal mind, its nature and functions, in the different orders of animal life. In ordinary use the term is synonymous with comparative psychology,— a term expressing the fact of the necessary starting-point of the science from the human mind, of which alone we have direct knowledge. This term, however, may be applied to any department of psychology whose method is comparative — for example, folk psychology, the study of the mental life of different races of men — and the more definite name, animal psychology, is therefore to be preferred. The interest of the science is threefold: in itself it grants insight into animal nature and life; in relation to man it lends light to anthropology and psychology, especially with reference to human instincts and impulses; and it has a deep

bearing upon the problems of evolution, both biological and mental. With regard to these latter two interests, it is a branch of genetic psychology (q.v.), treating, together with folk psychology, the phylogenetic as distinct from the autogenetic problem; that is, the question of mental evolution as distinct from mental development of the individual.

Animal psychology, as a science, dates from the middle of the last century, finding its rise in the movement of thought inaugurated by Charles Darwin. The first suggestion, however, of a genetic psychology was made by Aristotle (385–322 B.C.), who laid the foundation for so much of modern thought. The organic world, he said, forms an ascending scale, all of whose numbers are differentiated from inorganic bodies by an inner impelling principle, a "psyche" or soul, which employs a number of organs to realize its purposes. The soul of the plant performs the functions of assimilation and reproduction only; that of the animal has besides the faculty of feeling, and, in the higher orders, memory. The soul of man, in addition to all these, possesses the faculty of knowledge or reason, and is the end or goal of the process of nature's ascent. Despite this profound hint of the father of logic and psychology, almost the only reference to the animal mind for many centuries is in form of very doubtful anecdotes of individual cases of animal sagacity. Pliny tells the story of an elephant that was punished during a performance for his bad dancing, and set to work in the night to practise, so that he could do it better the next time — a good example of a familiar type. Descartes (1596–1650) looked upon the body as a mere automaton, to which mind or soul is essentially opposed in nature — man, however, being a combination of the two. But the animal does not possess mind and is thus merely an unconscious machine. The logical outcome of this doctrine is that animals cannot even feel pain; for sensations, he says, belong to the body, but the soul alone can be conscious of them. It is somewhat doubtful whether Descartes himself was not inconsistent here, and admitted that animals could feel while denying them the cognitive aspect of sensations. His followers, however, notably Bossuet and Malebranche, held that sensations in the animal are nothing more than mechanical, unfelt movements, and used the argument to justify vivisection. Pascal welcomed the doctrine because it relieved the divine goodness of the charge of animal suffering. The most interesting application of the view, however, is that of La Mettrie (1709–51), one of Darwin's precursors in holding a theory of evolution. If the animal is a machine, he said, man is just as much a machine, and his so-called soul or mind is merely a higher development of the material animal functions. The animal is thus made the measure of man, a false animal psychology the basis of a false human psychology.

But the modern theory of evolution, noted in the work of Darwin, took precisely the opposite standpoint. Man is not a machine, but possesses mind; the animals, too, must then possess mind of some sort or degree. Physically man is related to the lower animals through a long process of evolution: we should expect, then, a mental evolution co-ordinate with this biological evolution. This conviction gave birth to animal psychology, first undertaken, in support of a theory which had to win its way, by Darwin himself, Romanes and Lindsay as pioneers. Their works are marked by industrious observation and collection of facts; but the first flush of a theory prevented the most sober elimination, collation, and interpretation. Now, relieved from the burden of proof first cast upon it, animal psychology is being investigated with an increasing degree of scientific accuracy and careful experimental method.

There must, of course, always be one fundamental difference between the methods of human and animal psychology. The former is always, in the last analysis, introspective; the latter never can be. We are conscious of our own minds; but that of the animal is forever outside of such direct knowledge. The animal psychologist, therefore, can only study phenomena, the objective manifestations of the animal's mental life; and from these he must infer what that inner life is. In this fact lie the fundamental difficulty of the science and its most fruitful source of error. The observer may of course underestimate the animal mind — a mistake hardly probable now. The great danger lies rather in overestimation. The "psychologist's fallacy" of importing into other minds the processes of his own is here possible as nowhere else. We know no mind save that of man: there can be no thought or discussion of mental processes except from this basis. Through lack of language the animal can tell us nothing of its mind — we must infer; and even the most careful psychologist is liable to read into the facts too high an interpretation. This danger is often increased by an inclination to see things in the best light and to observe facts as interesting as possible; or by a false ideal of generosity to the animal, denying man the "conceit" of usurping the highest faculties. Special care must be observed in regard to the animal anecdote, liable to be colored by imagination or to be ill-authenticated; and it must be remembered that such stories relate in general to pets, individual cases of specially gifted animals living in a human environment. Thorndike well says: "Most of the books do not give us a psychology, but rather a eulogy, of animals. . . . Anecdotes give really the abnormal or super-normal psychology of animals." All these latter dangers may be avoided; but the "psychologist's fallacy" of unintentionally humanizing the animal is an inevitable difficulty which must always be reckoned with. Wundt cites and comments upon one of the stories about ants from Romanes' 'Animal Intelligence,' which is full of instances of the various fallacies mentioned: "A friend of the ants gives this account: At one formicary half a dozen or more young queens were out at the same time. They would climb up a large pebble near the gate, face the wind, and assume a rampant posture. Several having ascended the stone at one time, there ensued a little playful passage-at-arms as to position. They nipped each other gently with their mandibles and chased one another from favorite spots. They, however, never nipped the workers. These latter evidently kept a watch upon the sportive princesses, occasionally saluted them with their antennæ in the usual way, or touched them upon the abdomen, but apparently allowed them full liberty of action. . . . Why should not a number of young queens have been crowded together upon a pebble, and some workers have been

with them, and occasionally touched them with their antennæ, as ants do everywhere? But that they 'sported' and played, that the others 'kept a watch upon them' like chaperones, and now and then did homage to them by 'saluting' — that is all due to the imagination of the observer. He would hardly have told the story as it stands had not zoology introduced the misleadingly suggestive term 'queens' for the mature female insects. If the adults are 'queens,' the young females must, of course, be 'princesses,' and since no princess ever went out without an attendant or chaperone, the rest of the narrative follows as a matter of course." Even the most sober observation may err if there be no variation of circumstances by experiment. Huber found that an ant, if taken from the nest and returned after four months, was received in a friendly way by its former companions, while ants from a different nest, though of the same species, were driven away. This was considered evidence of the accuracy of memory in these insects. But Lubbock found that ant larvæ taken from the nest and not returned until they were fully developed were received with the same cordiality; and Bethe, that a strange ant was so "recognized" if it had been previously dipped into an impounded mess of the home ants. This recognition was thus seen to be merely a chemo-reflex, perhaps through a specific odor.

The only sound basal principle for a true animal psychology is that laid down by Lloyd Morgan: "In no case may we interpret an action as the outcome of the exercise of a higher psychical faculty if it can be interpreted as the outcome of the exercise of one which stands lower in the psychological scale." Wundt points out that this is nothing other than the well-known law of economy which is so fundamental in physical science; and that animal psychology, by often refusing the simplest explanation, has thus adopted an implicit principle exactly opposite to that of all other exact science. Groos points out an important truth in relation to this law of economy, and indicates the trend of present scientific method in animal psychology, when he says: "If the observation of animals is to be rendered fruitful for the unsolved problems of anthropology . . . attention must be directed less to particular resemblances to man and more to specific animal characteristics." This does not mean that the observer of animals need not be a psychologist in the proper sense; for lack of training in human psychology has been a fruitful source of error in the investigation of the animal mind. Mental facts cannot be interpreted at all by one who does not know the laws and processes of the human mind, since it is the only mind we know. No more can the animal psychologist dispense with training in biology. "It is necessary," says Morgan, "that accurate observation and a sound knowledge of the biological relationships of animals should go hand in hand with a thorough appreciation of the methods and results of modern psychology." "The animal psychologist," says Groos, "must harbor in his breast not only two souls, but more; he must unite with a thorough training in physiology, psychology, and biology, the experience of a traveler, the practical knowledge of the director of a zoological garden, and the outdoor lore of a forester."

Exact experimental methods are gradually taking the place of the animal anecdote and the more loose general observation. Laboratory study of animals, where conditions can be standardized and environment controlled, even at the risk of some degree of artificiality, is leading to surer results than were ever possible through former haphazard methods. Of course such investigation is most practicable in the cases of the micro-organisms whose investigation would be otherwise impossible. Careful study of these under the microscope has yielded data pointing to the presence of mind far down in the scale of life, as evolution would lead us to expect. Says Binet: "If the existence of psychological phenomena in lower organisms is denied, it will be necessary to assume that these phenomena can be superadded in the course of evolution in proportion as an organism grows more perfect and complex. Nothing could be more inconsistent with the teachings of general physiology, which shows us that all vital phenomena are already present in undifferentiated cells." Jennings thinks that the poramecium, one of the *Protozoa*, is the lowest in the scale, its actions being explicable by "simple irritability, or the property of responding to a stimulus by a fixed set of movements."

With regard to methods of experiment upon the larger animals, such as dogs and cats, Thorndike's investigations may be cited. He placed a number of animals in cages and studied their actions when under the powerful motive of hunger. His results have tended to lessen, rather than increase, opinion as to the high character of the intelligence of these animals. His work, he says, "has rejected reason, comparison or inference, perception of similarity, and imitation. It has denied the existence in animal consciousness of any important stock of free ideas or impulses, and so has denied that animal association is homologous with the association of human psychology." Mills strongly opposes this method, and inclines toward the explanation of animal action by the higher mental powers. Groos has made a most important contribution to the science by pointing out the psychological and biological significance of animal play.

In general, Aristotle's statement of the chasm between man and the lower animals still stands. There is not sufficient evidence to declare animals rational. The primary acts of the animal mind are cognition and recognition, which involve the associative faculties; and there have been observed no activities which would be sufficient ground for attributing to the animals the higher powers of conception and reasoning. Emotions they certainly do possess; they manifest an æsthetic sense. Yet there is no proof of æsthetic judgment in relation to an ideal; the powers of imagination and thought are essentially human. Even in their play, says Wundt, there is no inventiveness, no imaginative activity. Neither is it necessary to postulate on animal conscience for explanation of the facts which seem to point toward such an ethical sense. Most of the problems of the animal mind and of its varying degrees in different orders centre in the theory of instinct (q.v.).

As animal psychology had its real birth in the theory of evolution, it is in connection with this that its greatest importance lies. Most of its problems are common to biology and psychol-

ogy. All of its questions have a deep bearing upon biological evolution which, it is now seen, must take account of the mental processes at different stages in the life-forms if it is to be at all adequate; just as mental evolution, on the other hand, must recognize the influence of the evolution of the physical organism. The future theory of evolution will be psycho-physical. This mental factor in biological evolution is already seen in the theories of sexual selection, of mimicry, and of organic selection.

Bibliography.—The best introduction to the subject, eminently sane and modern, is C. Lloyd Morgan's 'Introduction to Comparative Psychology' (Lond. 1894); Wundt, 'Human and Animal Psychology' (trans. 1896); Groos, 'The Play of Animals' (trans. 1898); The Play of Man' (trans. 1901); Morgan, Animal Life and Intelligence' (1891); 'Habit and Instinct' (1896); Morgan, 'Animal Behavior' (1900); Thorndike, 'Animal Intelligence' (1898); Darwin, 'The Origin of Species' (Lond. 1859, N. Y. 1901); 'The Descent of Man' (Lond. 1871, N. Y. 1901); Romanes, 'Mental Evolution in Animals' (1883); 'Animal Intelligence' (1883); Binet, 'Psychic Life of Micro-organisms' (1894); Lubbock, 'Ants, Bees, and Wasps' (1882).

An'imal Sym'bolism in Ecclesiastical Architecture, a work by E. P. Evans; a work designed to trace the wide use of animal symbols in religious relations. The story of this symbolism in its application, with modifications, in architecture, is told with fullness of knowledge and sound judgment of significance of facts.

An'imal Wor'ship, a practice found to prevail or to have prevailed in the most widely distant parts of the world: in India, where it is a consequence of the belief in the transmigration of souls, according to which the soul of a god may pass into the body of an animal; in the heart of Africa, where it is still in life; in South America, where very remarkable instances of it were met with by the earliest Spanish visitors; but its most extraordinary developments were in ancient Egypt. Nearly all the more important animals found in the country were regarded as sacred in some part of Egypt. Some animals were held sacred throughout the whole land, but in many cases the animals enjoyed a local reverence only, an animal that was worshipped in one nome might be an object of aversion in the next and destroyed at every opportunity. The degree of reverence paid to the sacred animals was such that the voluntary killing of one was punishable with death, and if any one killed an animal involuntarily in a nome in which it was held sacred he was punished by a fine. Throughout Egypt the killing of a hawk or an ibis, whether voluntary or not, was punished with death. So strong was the feeling of the people on this point that when it was of the utmost importance to the Egyptians that they should conciliate the Romans, even the intercession of the king was impotent to save from the fury of the people a Roman soldier who had killed a cat. The animals were regarded as sacred to the deities, and the worship paid to them was symbolical. The Egyptian idols always bore on a human body the head of the animal sacred to the god represented by the idol. Only in three cases were certain animals believed to be incarnations of the deities themselves. These were at Memphis, where the bull Apis was worshipped as an incarnation of Phtha; at Heliopolis, where the bull Mnevis was reverenced as an incarnation of Osiris; and at Mendes, where a goat received worship as an incarnation of Khem.

An'imal'cule, the diminutive of animal; an old name applied to animals of microscopic size, and now frequently used for many *Protozoa*, such as the *Amœba* and various *Infusoria*. The term is not now used in zoology in any strict significance, nor employed in classification.

An'imals, Cruelty to. The earliest laws for the prevention of cruelty to animals were passed in England, whence the movement spread to the Continent and the United States. The first society for the prevention of cruelty to animals in the United States was chartered in 1866; and the agitation by similar societies has resulted in laws in almost every State providing for the punishment of cruelty to domestic animals by fines from $5 to $100, imprisonment from 30 to 60 days, or both. These societies work also to prevent cruelty by education, advice, and personal effort in enforcing the law.

An'ima Mun'di, ăn'ĭ-mȧ mŭn'dĭ ("soul of the world"), an ethereal essence considered by ancient philosophers as the informing principle of the universe of matter and bearing the same relation to it that the human mind does to the body. The conception originated in the East and was held by the Egyptians. Anaxagoras (q.v.), one of its earliest Western exponents, believed that it gave form to the universe; Plato treats of it at large in his 'Timæus'; Aristotle considered the world a living entity, but informed by an external spirit. Nearly all philosophical sects dallied with the idea. The Stoics thought it the sole vital principle of the universe, but not the universe itself in a different shape, as the doctrine of pantheism imputed to them would imply. In modern times it appears in the works of Cornelius Agrippa (who calls it *spiritus mundi*), Paracelsus, Van Helmont, Giordano Bruno, Sebastian Franck, Jacob Boehme, etc., in More and Cudworth, in the later Platonists, and in the philosophy of Schelling, who has incorporated it into his whole system.

Anime, ȧ-nẹ-mạ, a resin supposed to be obtained from the trunk of an American tree (*Hymenœa courbaril*). It is of a transparent amber color, has a light, agreeable smell, and is soluble in alcohol. It strongly resembles copal, and, like it, is used in making varnishes. Specific gravity is 1.028 to 1.054.

An'imism, the system of philosophy propounded by Stahl, and based on the idea that the soul (*anima*) is the seat of life. In modern usage a term applied to express the general doctrine of souls and other spiritual beings, and especially to the tendency, common among savage races, to explain all the phenomena in nature not due to obvious natural causes by attributing them to spiritual agency. Among the beliefs most characteristic of animism is that of a human apparitional soul, bearing the form and appearance of the body, and living after death a sort of semi-human life.

Anio, ä'nẹ-ō, **Aniene,** or **Teverone,** an Italian river tributary to the Tiber, which it enters from the east a short distance above Rome.

Ankerite, a carbonate belonging to the calcite group of minerals. It is intermediate between calcite, magnesite and siderite, the normal mineral being a carbonate of calcium, magnesium and iron, having the formula $2CaCO_3.MgCO_3.FeCO_3$. It occurs in rhombohedral crystals which have perfect rhombohedral cleavage, a hardness of 3.5 to 4, specific gravity of about 3, vitreous to pearly lustre, and usually white color. It also occurs in granular, crystalline and compact masses.

An'nals of a Sportsman, a work by Ivan Turgeneff, consists of 22 short sketches of Russian peasant life, appearing in book form in 1852 and establishing the author's reputation as a writer of realistic fiction. Turgeneff represents himself as on a hunting trip through the country districts, noting the local life and social conditions, and giving truthful studies of the state of the serfs before their liberation by Alexander II.; his book being one of the agencies that brought about that reform.

Annam, ăn'näm'. See ANAM.

Annamaboe, ä'nä-mä-bō', a seaport town, with a fort, on the Gold Coast, in western Africa, 10 miles east of Cape Coast Castle. It was at one time a principal mart for slaves, in trafficking in which many of its inhabitants became wealthy, and is still a place of considerable trade. Pop. about 5,000.

An'nan, a Scottish seaport and parliamentary borough in Dumfriesshire, on the Annan River. It has railroad connection with Glasgow, Carlisle, and Edinburgh, and water connection with Liverpool and Whitehaven. The important manufactures are tanning, rope-weaving, and cotton-spinning. Pop. (1901) 5,804.

Annan, a river of Scotland, having a course of about 50 miles, flowing from north to south through the centre of Dumfriesshire to the Solway Firth, its sources being not far from those of the Tweed and Clyde.

Annap'olis, Md., the capital and port of entry of Maryland and county-seat of Anne Arundel County; on the Severn River, near Chesapeake Bay and several railroads; 40 miles east of Washington, D. C. It is in a fruit and berry-growing region; has oyster-packing plants, marine railway, glass factory, a national bank, daily, weekly and other periodicals, and a property valuation of $3,000,000; is widely known as the seat of the United States Naval Academy, and contains also St. John's College, several State buildings, a convent, a house of Redemptorist Fathers, residences of many naval officers, and bronze statues of Gen. John de Kalb and Chief-Justice Roger B. Taney. The city was founded in 1649 and was first named Providence. It received a city charter and its present name, in honor of Queen Anne, in 1708. The first Federal Constitutional Convention was held here in 1786, and Washington surrendered his commission in the Senate-room of tne State House. Pop. (1900) 8,525. (Powell, 'Historic Towns of the Southern States,' 1900.)

Annapolis, a town in Nova Scotia, the capital of Annapolis County, and up to 1750 of the whole peninsula, situated on an arm of the Bay of Fundy, at the mouth of a river also called Annapolis, 95 miles west of Halifax. The place was originally called Port Royal, and is one of the oldest European settlements on the American continent. Pop. (1901) 1,019.

Annap'olis Convention. This small gathering was held 11 Sept. 1786, to discuss proposed changes in the Articles of Confederation. By the time it met, the Confederation had utterly broken down: Congress could not find means to carry on the government, and the Annapolis Convention was anxiously looked to as the last hope by the business interests. Only five States were actually represented,— New York, New Jersey, Pennsylvania, Delaware, and Virginia. These, however, were precisely the ones which wished the entire Confederation remodeled. New Jersey had instructed its delegates to accept nothing but a new federal government; and the New York group, headed by Alexander Hamilton, was equally zealous for a stronger system. John Dickinson, one of the chief authors of the Articles of Confederation, was made chairman; and a committee was appointed to prepare a report, which was drafted by Hamilton, though he was not on the committee. This report recommended that the States they represented should agree, and try to induce the others to agree, "to meet at Philadelphia on the second Monday of the next May, to consider the situation of the United States and devise such further provisions as should appear necessary to render the Constitution of the Federal government adequate to the exigencies of the nation; and to report to Congress such an act as, when agreed to by them and confirmed by the legislatures of every State, should effectually provide for the same." They then adjourned; but this call led to the convention of 1787, where the Constitution was adopted.

Ann Arbor, Mich., city and county-seat of Washtenaw County, on the Huron River, and the Michigan Central; Detroit, Ypsilanti & Ann Arbor and the Ann Arbor Railroads. It is situated among the picturesque hills of Southern Michigan, 38 miles from Detroit, and is regarded as one of the most desirable residential cities in the middle West. Here is the seat of a famous school of learning, the University of Michigan. (See MICHIGAN, UNIVERSITY OF.) Ann Arbor has, among prominent buildings, a homœopathic hospital, county court house, post-office building, high school and numerous churches and public and private schools. It is the business centre of a large agricultural and fruit growing region and an important shipping point. It has extensive manufactures of agricultural implements, furniture, pumps, engines, boilers, lumber products, organs, pianos, flour, wagons, etc. The municipal government is vested in a mayor, elected every two years, and a city council. The subordinate city officials are mostly appointed by the mayor, who acts under a revised charter of 1895. The city has an extensive electric light system, water works plant and electric traction lines connecting with Jackson, Kalamazoo, Battle Creek, Detroit and other cities. It has daily and weekly newspapers and four national banks. It was originally settled in 1824 and was incorporated as a city in 1851. Pop. (1890) 9,431; (1900) 14,509; (1903) est. 17,200.

Annas, an'as (Hebrew, "merciful"), a Jewish high priest; appointed high priest by Quirinus, proconsul of Syria, about 7 A.D., and deposed

by Valerius Gratus, procurator of Judea, in 14 A.D. His family was wealthy and he was evidently very influential, as the office of high priest was held by five of his sons and his son-in-law, Caiaphas before 36 A.D. In the New Testament (Luke iii. 2, John xviii. 13, Acts iv. 6) Annas is mentioned as high priest conjointly with Caiaphas. The first hearing of Jesus was before Annas, who sent him bound to Caiaphas.

Annates, a certain portion of the year's fruits or revenues paid to the Pope and his court. The term properly denotes the sum of half a year's revenue of a vacant benefice (q.v.) payable by the new incumbent to the Pope. It was also used to indicate the tribute every bishop or mitred abbot was obliged to pay for the support of the Pope and cardinals, and the lesser sums they contributed for the support of members of the Papal household. These tributes or taxes were frequently a cause of contention between ecclesiastical and civil authorities. An effort was made to put an end to these contentions in the Councils of Pisa and Constance, and gradually all the minor tributes were abolished. In the Council of Basel it was decided to abolish every tribute of this kind, but to raise revenues for the antipope Felix exactions doubly severe were imposed on his adherents. In Germany the payment was satisfactorily regulated in the Concordat of Vienna (1448) and after several modifications it was finally abolished in 1803. In France the payment was stipulated in a Concordat between Innocent X. and Francis I.; it was finally refused entirely in 1789, and its abolition recognized in the Concordat of 1801. In England such sums were first paid to the Archbishop of Canterbury, later to the Pope, and transferred to the Crown in 1534, the sovereign at present retaining only those derived from bishoprics and Crown livings, the rest, since Queen Anne's time (see QUEEN ANNE'S BOUNTY), going to increase the poorer livings. The Pope used them to support himself, the cardinals, and other papal officials; to defray the expenses of nuncios, legates, bishops exiled from their sees, princes deprived of their thrones, envoys and vicars apostolic to missionary countries. As this source of revenue has been constantly falling off during the past century, the deficit is made up by the voluntary contributions of Catholics, known as «Peter's Pence» (q.v.). See Ferraris, 'Prompta Bibliotheca.' See FIRST FRUITS.

Anne, ăn, Queen of Great Britain and Ireland: b. at Twickenham, near London, 6 Feb. 1664; d. 20 July 1714. She was the second daughter of James II., then Duke of York, and Anne, his wife, daughter of the Earl of Clarendon, and was educated according to the principles of the English Church. In 1683 she was married to Prince George, brother to King Christian V. of Denmark. On the arrival of the Prince of Orange in 1688 Anne desired to remain with her father; but was prevailed upon by Lord Churchill, afterward Duke of Marlborough, and his wife, to join the triumphant party. After the death of William III. in 1702 she ascended the English throne. Her character was amiable but lacking in firmness, and she was influenced first by Marlborough and his wife and afterward by her favorite, Mrs. Masham. Most of the principal events of her reign are connected with the war of the Spanish Succession. The only important acquisition that England made by it was Gibraltar, captured in 1704. Another very important event of this reign was the union of England and Scotland, under the name of Great Britain, which was accomplished in 1707. She seems to have long cherished a wish to secure the succession to her brother James, but this was frustrated by the internal dissensions of the Cabinet. Grieved at the disappointment of her secret wishes, she fell into a state of weakness and lethargy and died. The reign of Anne was distinguished not only by the brilliant successes of the British arms, but also on account of the number of admirable and excellent writers who flourished at this time, among whom were Pope, Swift, and Addison. See Oldmixon, 'Life of Queen Anne' (1716); Ashton, 'Social Life in the Reign of Queen Anne' (1882).

Anne, Sister, the sister of Fatima in the tale of 'Bluebeard.' From the top of the castle tower she awaits the arrival of their brothers to rescue them.

Annealing, a process to which metals and glass are subjected in order to increase their ductility, or lessen their liability to fracture under sudden stress. It is usually effected by heating the substance to be annealed until it approaches softness, and then allowing it to cool very slowly. Copper, however, is best annealed by heating it to a high temperature and then plunging it immediately into water. Metals that are to be annealed should be heated in close vessels, so that they may not be affected by direct contact with the fuel. It is not uncommon to anneal large masses of metal or glass by allowing the fires in the heating furnace to go out, and permitting the furnace and its contents to cool together. The articles to be annealed are also often buried, while still hot, in lime, ashes, or some other poor conductor of heat, and left until cold. Metals that are to be drawn into wire, or rolled into sheets, or pressed into complicated shapes, usually require annealing during the process, as otherwise they are likely to become brittle and crack or break. Zinc, however, grows strong and flexible as it is drawn into wire, though it loses its flexibility and regains its crystalline structure if kept in boiling water for a time. It is usually taught that the object of annealing is to soften the material sufficiently to allow molecules to move slightly among themselves, and thus relieve the strains previously introduced by sudden cooling, or by the violent stresses to which the material has been subjected in the process of working. This theory is very possibly true to a certain extent, but the anomalous cases of copper and zinc, cited above, show that it can be regarded only as a first approximation to the ideal theory of annealing, which has yet to be discovered. See TEMPERING.

Annecy, ăn'sĕ', a town of eastern France, situated in the central part of the department of Haute Savoie at the northwest end of Lake Annecy. It has manufactures of silk, cotton, wool, and steel, and contains many buildings of historical interest, including a cathedral and the old castle of the counts of Genevois. Pop. (1901) 13,611.

An'nexa'tion, politically, the formal incorporation by a State with itself of territory previously under another government; usually territory contiguous to itself or its colonial possessions, or an insular neighbor, but only because other annexations are rarely desired, not from any principle of international law. The annexation may be by purchase, peaceful cession, or conquest. Existing laws and local authorities do not lose their binding force and title to obedience till the formal act of annexation is passed by the new power, or treaty or proclamation validates it, even after cession by the old; though that cession cancels all legal relation to the former sovereign power.

Annexations to the United States.— (1) The Louisiana Purchase (q.v.) from Napoleon, 1803: 1,171,931 square miles, including Alabama and Mississippi south of lat. 31° S.; the whole of Louisiana, Arkansas, Missouri, Iowa, Nebraska, North and South Dakota, Idaho, Montana, Oregon, Washington, and Indian Territory; Colorado and Wyoming east of the Rocky Mountains; Kansas, except the southwest portion south of the Arkansas River, and Minnesota west of the Mississippi. This was bought by Jefferson's administration for $15,000,000, $3,750,000 of it in assumption of claims of American citizens against France. The preliminary convention was signed by Livingston and Monroe 30 April 1803, and was confirmed by the Senate in special session 19 Oct. 1803, and by the House the 25th,— the extreme Federalists opposing it as unconstitutional, and the President acknowledging it to be so, but necessary.

(2) Florida (q.v.), 1819–21, from Spain: 59,268 square miles; price $5,000,000, entirely in assumption by the United States of claims of its citizens against Spain, and the relinquishment by it of claim to Texas and the boundary of the Rio Grande. The treaty was signed by the Spanish minister at Washington, 22 Feb. 1819; Spain refused to ratify it till after two years of vain insistence that the United States should refuse to recognize the independence of the South American States.

(3) Texas (q.v.), 1845: 376,133 square miles. Texas, originally part of the Mexican province of Coahuila, obtained its *de facto* independence in the war of 1836 against Mexico, was acknowledged by the other powers in 1837, and at once began the attempts for admission into the United States which had been the ultimate object of its first colonization by Southern settlers. In the previous April a treaty of annexation with Texas had been concluded, but was rejected by the Senate. President Tyler on the last day of his term sent a special messenger to secure the consent of the Texas Congress to annexation; it acceded unanimously, a popular convention of 4 July ratified the action, and the annexation was completed by a joint resolution of the United States House 16 Dec. 1845, and of the Senate on the 22d. It claimed west to the Rio Grande, taking in all the immemorially Spanish province of Coahuila, a circumstance which led to the Mexican war.

(4) New Mexico and Upper California, seized from Mexico in the war of 1847, and annexed by the treaty of Guadalupe-Hidalgo, 2 Feb. 1848: 545,783 square miles. Besides the present State of California it included Utah and Nevada, the most of Arizona and New Mexico, and Colorado west of the Rocky Mountains. Price, $15,000,000, and the assumption by the United States of $3,250,000 in claims of its citizens against Mexico. The portion of New Mexico east of the Rio Grande was claimed by Texas, which afterward received $10,000,000 from the United States in release.

(5) The Gadsden Purchase (q.v.), 1853, from Mexico: southern Arizona and New Mexico from the Gila valley to Chihuahua (the Mesilla valley), 45,535 square miles; price $10,000,000.

(6) Alaska (q.v.), 1867: 590,884 square miles; price, $7,200,000. Bought by the United States from Russia by treaty of 30 March, ratified by the Senate in special session 20 June.

(7) Hawaii, 6 July 1898; 6,740 square miles; price, a compensation to the queen, Liliuokalani, recently adjusted at $200,000. Annexed by a joint resolution of Congress.

(8) Porto Rico, the Philippine Islands, and Guam of the Ladrone Islands, 1898; taken from Spain as the result of war; ceded by Treaty of Paris, 10 Dec. 1898; about 150,000 square miles; price, $20,000,000, plus $100,000 subsequently paid for two small islands omitted from the treaty.

(9) Tutuila, with the smaller islets of Tau, Onesinga, and Ofu, of the Samoan group, 1899; 54 square miles, including the harbor of Pago-Pago; obtained by tripartite treaty with Great Britain and Germany.

(10) A number of small scattered islands in the Pacific, taken at different recent times, including Wake, January 1899. See UNITED STATES — *Territorial Expansion.*

An'nie Kil'burn, a novel of New England life, by W. D. Howells, published in 1888. It is a character study of a woman in her later youth who returns to her native town after a long sojourn in Rome, unfitted by her life abroad for sympathy with her girlhood friends, yet with no diminution in the strength of her Puritan conscience.

Anniston, ăn'nĭs-tŏn, Ala., a city in Calhoun County; on the Louisville & N., and Southern R.R.'s. It is in one of the most important coal- and iron-mining regions of the country; is a trade centre for cotton and agricultural products; and is noted for its manufactures of iron and steel, cotton goods, bricks, cordage, and other articles. Anniston is the seat of the Southern Female College and the Noble Female Institute; has three national banks, 30 churches, 10 daily and weekly periodicals, and a property valuation of $5,500,000. It was founded by the Woodstock Iron Co. in 1872. Pop. (1900) 9,695.

An'nuals, or **Monocylic Plants,** are those that complete their life histories — germinate, grow, mature, seed, and die — in a single vegetative period. In garden parlance the term is extended to plants that are preferably raised from seed planted each year. Annuals are especially common in dry climates and waste places, and among them are some of the most brilliantly colored and otherwise attractive of ornamental plants.

Annuals, in literature, the name given to a class of publications enjoying at one time an immense yearly circulation, and distinguished by great magnificence both in binding and illustration, which render them much sought after

as Christmas and New Year presents. Their contents were chiefly prose tales and ballads, lyrics and other verse. The earliest was the 'Forget-me-not,' started in 1822, and followed next year by the 'Friendship's Offering.' The 'Literary Souvenir' was begun in 1824, and the 'Keepsake' in 1827. Among the names of the editors occur those of Alaric A. Watts, Mrs. S. C. Hall, Harrison Ainsworth, Lady Blessington, and Mary Howitt. The popularity of the annuals reached its zenith about 1829, when no less than 17 made their appearance; in 1856 the 'Keepsake,' the last of the series, ceased to exist.

Annu'ity, a yearly payment of money to a specified person or persons, for a term of years, for life or perpetually. The varieties and combinations of annuity payments are almost as numerous as the contingencies or desiderata of human life; each having figured so largely in law as to receive a specific legal title. If the annuity is for a definite term of years, it is called an annuity certain; if forever, continuing to heirs or specified successors, a perpetual annuity or perpetuity; if for a limited period, a term annuity; if during the whole of a given period, not cut short by any contingent event, a whole-term annuity; if for a short period, a short-term annuity; if it does not begin till after a certain date, a deferred annuity; if not till after the occurrence of some specified event, a contingent annuity; if its beginning or duration is based on the continuance of a life or lives, it is called a life annuity; if for the time that certain persons survive, a temporary life annuity; if on any life provided another is living, or some event happen or not, a contingent life annuity; if it begin only after some death or deaths, a reversionary annuity; if for the duration of the longest of two or more lives, a joint-life annuity; if to the survivor of two or more, a survivorship annuity. There are increasing and decreasing annuities, their nature obvious from their titles. An annuity ceasing only with the death of the annuitant, and with a proportionate part of the next payment made to the heirs, is called a complete annuity; if it ceases with the last payment made to the living, a curtate annuity. This by no means exhausts the forms or combinations possible or even actual; nor does it fully define even those mentioned. Thus, in a joint-life annuity, what is to happen on the successive deaths up to the last? The shares of the dead might return to the estate, but in practice are successively added to those of the survivors in equal portions till the last survivor receives the whole. In contingent annuities the commonest contingency which terminates it is that the annuitant shall become self-supporting, as on marriage or remarriage or the attaining of majority; as when a man provides for his widow or daughter or son by will.

In respect of object, annuities may be broadly divided into two sorts: those providing for others and those providing for one's self. The former are probably the oldest, and are of course testamentary, taking the place of a legacy in the lump. Till modern times these were chiefly (and with great European houses are still so) charged directly on the private property of the testator in the hands of legatees or trustees. In Europe these permanent charges on property form a feature of the highest social and even political importance. The entailed estates are always incumbered with multitudes of annuities to connections or dependents of the houses, absolutely fixed, while the income from which they are to be paid may shrink indefinitely. But for a century and a half it has been gradually taken up by great incorporated companies and combined with the business of life insurance (q.v.). The insurance companies pay the annuities on contracts matured by the death of the testator, the payments beginning either then or at a specified time thereafter. In America this system has also absorbed almost entirely the old contractual annuities, in which the annuitants buy incomes for themselves by paying a lump sum to a person, company or public body for a term or life.

These contractual annuities, though based on the same calculations and mathematically identical, are historically of two distinct kinds as respects their object: the one seeking security, the other investment. The latter is the older, and resulted from conditions now obsolete; partly the paucity of investment securities, partly the laws against usury, which could be evaded by annuities, as a given sum was paid for by a return of services, and the element of interest did not formally enter into it at all. Hence the favorite method of borrowing money by the great mediæval companies and houses, and municipalities and States as well, was by annuities, sold on a rough estimate of the chances of life; in which the buyers were always keener than the sellers, and till very modern times the bargain was always against the payers of the annuity. Many shrewd investors accumulated great properties by careful selection of annuities on good lives, being allowed to propose the lives upon whose duration they laid this wager (until scientific mortality tables were constructed). The interest on government debts is a perpetual annuity; and of course any investment at interest is an annuity for its term, but such investments are not classed among annuities as the term is currently used.

The other object, that of securing one's self against the chances of fortune, though reached by the same means, has till recently had one broad distinction,— it was done at once and usually in early life, instead of in small lots as money accumulated. It was commonly the sinking of an inherited property (rarely an acquired one), by women, or by men of quiet tastes and unsuited for the struggle of business life, to produce a sure moderate income free from care and business chances. Naturally such annuities are much commoner in the older countries than in America, though steadily growing here from the same causes. Large inherited fortunes are rare in new countries, and the desire to live in unventuring ease equally so, but as family properties increase and the struggle for life grows harder, the annuity system grows likewise. But it has been vastly extended in recent years by its junction with the insurance system, enabling even relatively poor men to buy an income for their dependents after death, or themselves in old age, in small installments instead of an impossible lump sum; and also leaving to a widow a steady income for a term of years or life, in place of a lump sum to be invested by herself or trustees, and possibly

mismanaged or lost or embezzled. Therefore, both in its ease of purchase and in its advantages of payment, it is steadily growing in favor, and becoming larger in proportion to the total of life-insurance dealings.

Historically, annuities are probably as old as the great Assyrian-Babylonian times, in the 7th and 6th centuries before Christ, when great banking houses that lasted for generations, and commercial and mercantile facilities, were well developed; but the first positive mention is brought out by the Falcidian Law of Rome, 40 B.C., which enacted that not more than three fourths of a property should be willed away in specific legacies. As this could not be obeyed unless some method of valuing annuity legacies was devised, the following rough estimate was accepted: up to 30, 30 years more of life; up to 60, as many as were wanting to make up 60. This extremely defective calculation — which assumed that a life over 60 was not worth even a year's purchase, and was very inaccurate for others — was replaced by the great Roman jurist Ulpian (d. 228 A.D.) with one much better, though still imperfect; but interesting as the first known table of life probabilities graduated with reference to age, and, strangely enough, revived and used by the Tuscan government in the early 19th century, long after more scientific ones were in use. It is as follows:

Birth to 20,	30 years	44 to 45,	15 years
20 to 25,	28 "	45 to 46,	14 "
25 to 30,	25 "	46 to 47,	13 "
30 to 35,	22 "	47 to 48,	12 "
35 to 40,	20 "	48 to 49,	11 "
40 to 41,	19 "	49 to 50,	10 "
41 to 42,	18 "	50 to 55,	9 "
42 to 43,	17 "	55 to 60,	7 "
43 to 44,	16 "	60 and up,	5 "

This contained no interest computation. Until the 18th century there was little advance in the scientific aspects of the business: it remained a speculation, though an extensive and recognized one, and England under William of Orange may almost be said to have maintained her national existence by borrowing money on annuities, as the Dutch had to some extent before it. The researches of Pascal, Fermat, and Huygens in the 17th century into the theory of probabilities greatly advanced the accuracy of calculations; in 1742 Mr. Thomas Simpson published his 'Doctrine of Annuities and Reversions,' one of the landmarks of the business; and in 1762 the Equitable Assurance Society, the first insurance company of the world, was started primarily to do annuity business, which is the parent of life insurance, though now but a minor incident in it. Several other companies were founded shortly after. The real foundation of modern life insurance, however, and of scientific annuities as well, was the publication in 1771, by Richard Price, of his Northampton Table of Mortality. This estimated the term of life-average too low, but it was the predecessor of the Carlisle and other tables on which modern life insurance is built, now supplanted by the actual experience for generations in numberless great offices.

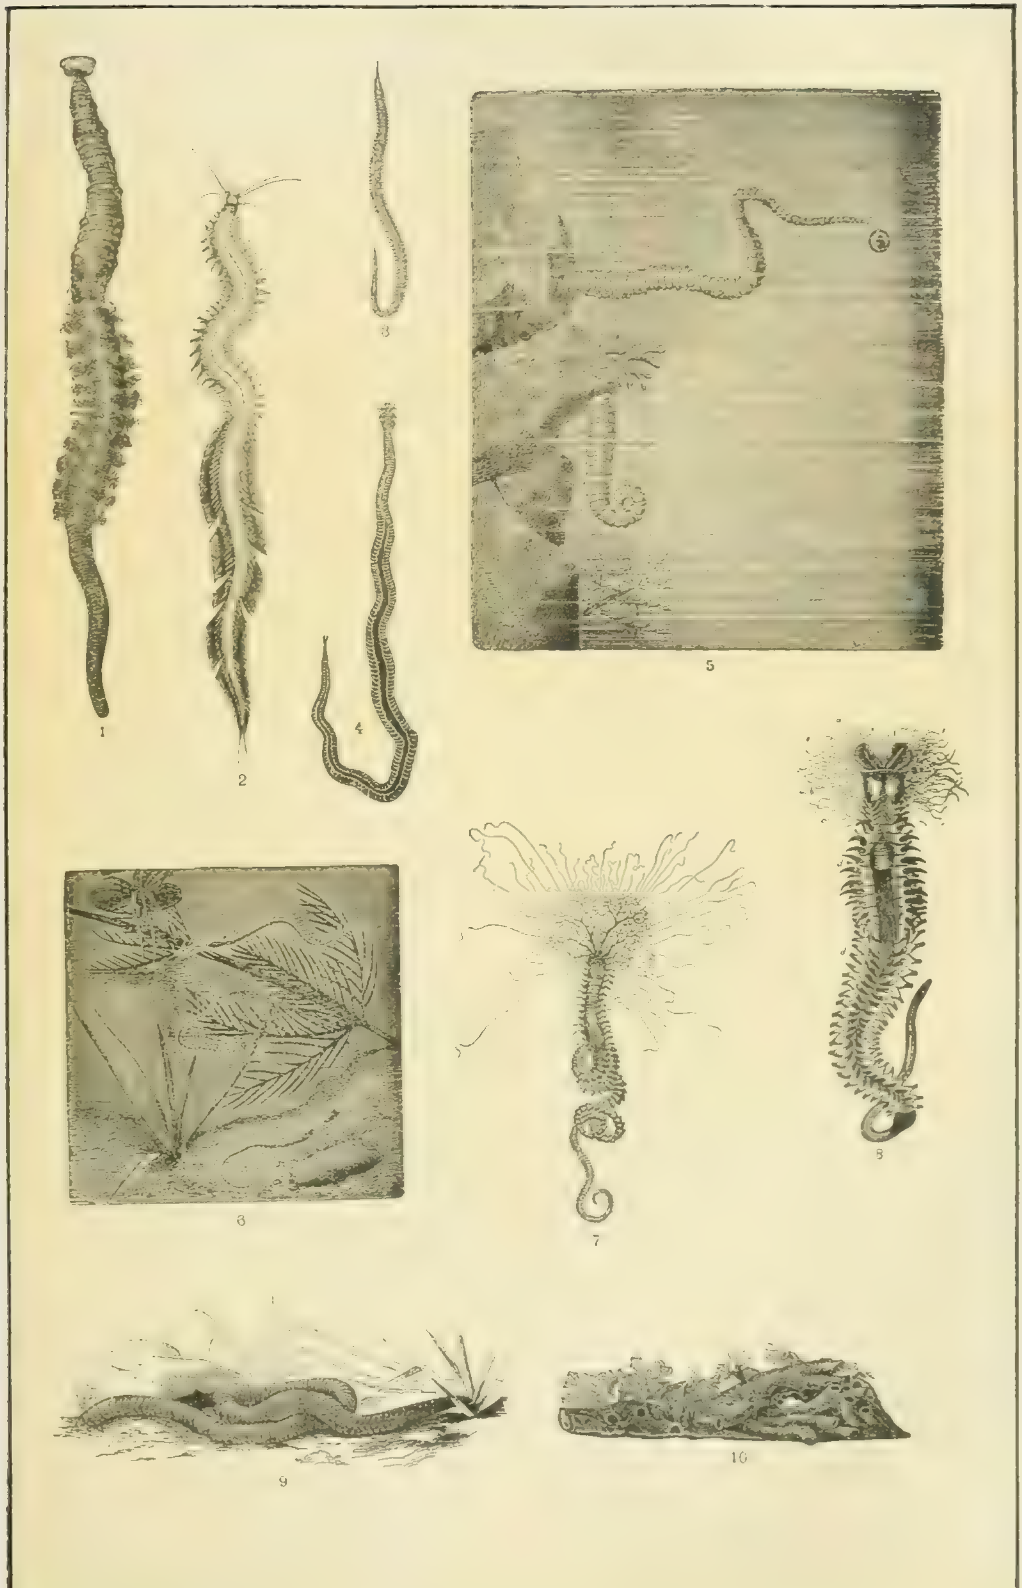
It is obvious that while the rate of mortality is a determining factor in annuity rates as much as insurance rates, its incidence is exactly in reverse. That is, the higher the rate of mortality and the shorter the average term of life, the less money in gross will have to be paid on a contingent annuity contract, and consequently the less will be the sum needed to sink in it, or in current phrase, the lower the rate of annual premium. Conversely, the older the buyer is, and consequently the shorter his expectation of life, the less his annuity is worth. On the contrary, the less an individual's expectation of life under an insurance contract, the higher must his premium be to accumulate sufficient money in the assumed period to amount to the promised sum. The factor of interest is the same for both: the higher the interest, the lower the premium or the initial sum paid. In the now frequent insurance contracts, where the principal sum is paid to the beneficiary in annuity installments, the question is one of interest complicated by the probabilities of the beneficiary dying before the payments are completed. More usually now, however, this latter element is eliminated by providing that in such case the remainder shall be paid to the legal representatives, so that it becomes an annuity certain. An interesting concrete illustration of the effect of overrating the mortality is the sale of annuities by the English government under the Northampton Table. This table had figured a correct total of deaths against an incomplete table of births in a given population, and consequently assumed too high a death rate; the government, therefore, fixed the annuity rate too low; and vast quantities of annuities were sold under Mr. Perceval's scheme of 1808 for funding the national debt. The actuaries discovered the miscalculation, and one of them in 1819 warned the government that it was losing £8,000 a month on these contracts; the advice was unheeded; buyers continued to be shrewder than the government and purchased largely of the attractive bargain, and in 1827 another actuary publicly announced that the government was losing £8,000 a week. The next year the sale was suspended, with a total loss to the government of not less than $25,-000,000.

The calculations for annuities are a part of actuarial science. In the United States the following are the approved rates of the best-managed companies: In consideration of $1,000 paid to a company the annuity granted to a person aged 40 would be $52.75; 45, $58.10; 50, $64.70; 55, $73.50; 60, $86.20; 65, $100; 70, $123.45; 75, $145.95; 80, $180.15. But, as stated, the pure annuity, sinking a large sum to buy a yearly income, does not figure largely in America.

Legally the annuity, whether charged to the person of the grantor or on specific real or personal estate, is treated as personal property except for purposes of inheritance or devisement, when it is held to be real property. A rent-charge, however, is a charge on specific real estate only, and is held to be real property under all circumstances.

An'nular'ia. See CALAMITIES.

An'nula'ta, or **Anneli'da,** a term applied to the phylum of sea-worms, comprising the most specialized worms. They are represented by the leeches, the earthworm, the nais of fresh water, and the marine annelids. The phylum is divided into four classes: (1) *Chætopoda,* (2) *Gephyrea,* (3) *Archi-annelida,* and (4) *Hirudinea.* In the more typical form they are characterized by their long, bilaterally symmetrical body,



1. Heteronereis.
2. Phyllodoce Laminosa.
3. Glycera.
4. Arenicola.
5. Rock Needle (Pontobdella muricata).
6. Nais Proboscidea.
7. Terrebilla Emmalina.
8. Hermella.
9. Common Earth Worm (Lumbricus agricola).
10. Tubes of Hermella Alveolata.

which is cylindrical, consisting of numerous segments either unarmed, or more usually provided with *setæ* alone, or with *setæ* and paddle-like appendages (*rami*). The head is simple, with a few simple eyes, or provided with tentacles (*antennæ*) alone, or with tentacles and *branchiæ*. An eversible pharynx, armed with teeth, is usually present. The alimentary canal is straight, the tubular stomach sometimes sacculated; the vent is always situated in the last segment of the body. The nervous system is well developed, consisting of a brain and a ventral ganglionated cord. The circulatory system is closed, with a dorsal and ventral, and lateral vessels connected by anastomosing branches in nearly each segment. A system of numerous paired segmental organs, the sexes are united in the same individual or separate. The embryo passes through a cleavage-stage (morula or blastula), gastrula, sometimes a neurula stage, and after hatching, development is either direct or there is a marked metamorphosis, the larva passing through a trochosphere and cephalala stage. Consult Parker and Haswell, 'Text-book of Zoology' (1897).

Annuncia'tion, the declaration of the angel Gabriel to the Virgin Mary that she was to become the mother of our Lord (Luke i. 26-38). Annunciation or Lady Day is a feast of the Church in honor of the annunciation, celebrated in the western Churches on 25 March. The institution of this festival is generally assigned to the 7th century. The Italian, formerly Sardinian, order of Knights of the Annunciation (*Ordine Supremo dell' Annunziata*) was instituted by Amadeus VI., Duke of Savoy, in 1360. It received statutes from Amadeus VIII. in 1409, was renewed in 1518, and raised to the first order of the Sardinian monarchy in 1720. The subject of the Annunciation has been a favorite with artists from Fra Angelico to Dante Gabriel Rossetti.

Annunzio, Gabriele d', ăn-noon'tse-ō, an Italian novelist and poet: b. near Pescara in 1864. He was educated at Prato, where he published at 14 his 'Primo Vere.' He is now one of the most conspicuous Italian writers of the day, having abandoned Italian traditions for modern French realism. His poems and novels are brilliant, but often frankly sensual as well as pessimistic, and both prose and verse have been severely criticised for their licentious spirit. 'Il Piacere,' his first novel (The Child of Pleasure, 1889), was followed by others entitled 'L'Innocente' (The Intruder, 1891); 'Giovanni Episapo' (1892); 'Il Trionfo della Morte' (The Triumph of Death, 1849); 'Le Vergini delle Rocce' (Virgins of the Rocks, 1896); 'Fuoco' (Flame of Life, 1900). His plays include 'Il Sogno d'un Mattino di Primavera' (1897): 'Il Sogno d'un Tramonto d' Autunno' (1898); 'La città Morte' (1898); 'La Gioconda' (1898); 'Francesca da Rimini' (1901). D'Annunzio's reputation is now international, his writings having been translated into English, French, and German. Among his poems are: 'The New Song' (1882); 'Interludes of Verse' (1883); and 'Marine Odes' (1893).

An'nus Mirab'ilis (Latin), «the wonderful year,» 1666. A year memorable for the great fire of London and the successes of British arms over the Dutch. Dryden has written a poem with this title, in which these events are described.

Ann'ville, Pa., a village in Lebanon County five miles west of Lebanon, the seat of Lebanon Valley College, an institution controlled by the United Brethren in Christ. It was founded in 1762. Pop. (1900) about 2,000.

Ano'a, a genus of Malayan buffaloes, particularly the small black species, with low, erect horns, called sapi-utan (*A. depressicornis*), and found in the highlands of Celebes. The genus was once classed with the antelopes.

Anob'ium, a genus of beetles belonging to the family *Ptinidæ*. It contains the death-watch insects, *A. striatum*, *A. tesselatum*, etc.

An'ode, the name given by Faraday (in 1832) to the electrode, or terminal, at which a current of positive electricity enters a battery or other electrical apparatus in which chemical work is performed. The term has since been extended so as to include the electrode by which a positive electric current enters a vacuum tube. The other electrode, in every case, is known as the «cathode.» The anode of a primary battery (see BATTERY) commonly consists of a plate or rod of zinc, while the cathode consists of a plate of carbon, or copper, or platinum. In electrolysis the anode and cathode both consist, usually, of platinum or carbon. In a vacuum tube the anode commonly consists of a wire or disk of platinum, while the cathode (which is varied in shape according to the purpose to which the tube is to be put) is usually made of aluminum or platinum.

An'o-don'ta, a subdivision of the fresh-water mussels (q.v.), abundant in the streams and lakes of the United States and most temperate countries. They have smooth, thin shells without hinge-teeth.

An'odynes. See ANALGESICS.

Anointing, an Oriental custom of applying oil to the head or unguents to the body. The Greeks and Romans, particularly the former, anointed themselves after the bath. Wrestlers used unguents in order to render it more difficult for their antagonists to get hold of them. The use of oil for ceremonial purposes is equally ancient. Its first mention is in Gen. xxviii. 18, where Jacob, in commemoration of a remarkable dream, is said to have set up a pillar and poured oil upon it. In the Mosaic law and several ancient religions a sacred character was attached to the anointing of the garments of the priests and things belonging to the ceremonial of worship. This could be done only with oil made for the purpose, and signified a consecration of the articles to the service of religion. Jewish priests and kings were anointed when inducted into office, and were called the anointed of the Lord, to show that their persons were sacred and their office from God. The Old Testament prophecies respecting the Redeemer style him, on account of his royal descent and his dignity, Messias, that is, the Anointed, which is also the meaning of his Greek name Christ. The custom of anointing still exists in the Roman Catholic and Oriental Churches (see SACRAMENTS), and is also frequently a part of the ceremony of coronation.

Anoka, ă-nō'kă, Minn., a small city, the county-seat of Anoka County, with manufactures of lumber, flour, and machinery. Pop. (1900) 3,769.

Ano'lis, a genus of slender, long-tailed, iguanid lizards of the American tropics, which are expert climbers and seek their insect food principally in trees and bushes. They have a pouch under the throat and the ability to change color. It is not surprising, therefore, that one of the species (*A. carolinensis*), a beautiful golden-green lizard, very common in our Southern States, and often kept as a pet, should be called the American chameleon. About 100 other species are known. See CHAMELEON.

Anom'aly, a deviation from a rule. That which deviates is called anomalous. In astronomy the true anomaly is the angle which a line drawn from a planet to the sun has passed through since the planet was last at its perihelion or nearest distance to the sun. On account of the planets not moving with the same velocity at all parts of their orbits, this angle does not increase uniformly; hence its name. The anomalistic year is the interval between two successive times at which the earth is in perihelion, or 365 days 6 hours 13 minutes 48 seconds. In consequence of the advance of the earth's perihelion among the stars in the same direction as the earth's motion, and of the precession of the equinoxes, which carries the equinoxes back in the opposite direction to the earth's motion, the anomalistic year is longer than the sidereal year, measured by the sun's return to the same position among the stars, and still longer than the tropical or common year, measured by the earth's return to the same equinox. It exceeds the latter by 25 minutes.

Anonaceæ, ăn-ō-nā'cĕ-ē, the custard-apple family, a natural order of trees and shrubs with simple, alternate leaves, destitute of stipules, by which character they are distinguished from the *Magnoliaceæ*, to which they are otherwise closely allied. Their flowers are commonly axillar, sometimes terminal. The calyx is persistent, with three deep divisions. The corolla is formed of six petals, disposed in two series. The stamens are very numerous, forming several series; their filament short, their anthers almost sessile. The carpels, generally aggregated in great number in the centre of the flower, are sometimes distinct, sometimes connected; each of them has a single cell which contains one or more ovules attached to the inner suture, and often forming as many distinct fruits (rarely one only in consequence of abortion); sometimes they are united together and form a kind of fleshy, scaly cone. The seeds have a horny endosperm deeply grooved, and this is another character which distinguishes them from the *Magnoliaceæ*. The *Anonaceæ* are mostly tropical plants belonging both to the Old and New Worlds, the papaw being the best-known American species. They are generally aromatic, a quality found chiefly in the bark, but also in the leaves and flowers, and to some extent in the fruit, all of which parts are consequently employed in the countries of which the plants are native as remedies and for seasoning. Many of them yield likewise an edible and nutritious fruit, extremely agreeable to the taste.

Anoph'eles, a genus of *Culicidæ* (mosquitoes), embracing those species of blood-sucking mosquitoes which carry and communicate to human beings, by biting, malarial diseases. See MOSQUITO.

An'oplothe'rium, an extinct primitive ruminant fossil in the Upper Eocene formations of Europe. It was among the first fossil vertebrates discovered in the gypsum quarries of Montmartre in Paris, and was named by Cuvier in 1822 from its defenseless character (Gr. ἄνοπλος, unarmed; θηρίον, beast), as it has neither tusks nor horns to protect itself from its carnivorous enemies. They form the type of a distinct family, in many respects intermediate between the swine and the true ruminants.

Anorthite, a triclinic feldspar, having the composition of a silicate of aluminum and calcium, $CaAl_2Si_2O_8$. It is especially interesting to the chemical mineralogist because it stands at one end of the albite-anorthite series of feldspars (see FELDSPARS). Its cleavage is perfect parallel with the base, and distinct parallel with the brachypinacoid. It is brittle, breaking with a conchoidal to uneven fracture. Its hardness is 6 to 6.5, and specific gravity about 2.75. It is usually colorless or white, sometimes grayish or inclining to brick-red. It occurs in glassy crystals in the ejected blocks at Mount Vesuvius, Italy.

Anos'mia, the loss of the sense of smell. This may be produced by: (1) Injury to the nerves of smell as they originate in the mucous membrane of the nose, in chronic nasal catarrh, in polypi, or in injury to the nose. (2) By injury to the olfactory bulbs or to the olfactory tracts. Such injuries occur in severe blows or falls, particularly in fracture of the ethmoid plate accompanying fracture of the skull. (3) By injury to the brain centres of smell, which are located in and about the uncinate gyrus. See SMELL.

An'selm, Saint, a celebrated theologian, regarded by some as the founder of scholasticism: b. Aosta, in Piedmont, 1033; d. Canterbury, 21 April 1109. At 27 he became a monk at Bec, in Normandy, whither he had been attracted by the celebrity of his countryman Lanfranc, then prior of the monastery there. When Lanfranc was promoted to the abbacy of Caen, Anselm was elevated to the dignity of prior, and in 1078 he was made abbot, which office he retained for 15 years. During this period he wrote his first philosophical and religious works: the dialogues on 'Truth and Free-will,' 'De Veritate,' and 'De Libertate Arbitrii,' and the treatises 'Monologion' and 'Proslogion,' and at the same time his influence made itself so strongly felt that Bec became the chief seat of learning in Europe. In 1093 Anselm was offered the archbishopric of Canterbury, which had lain vacant since the death of Lanfranc in 1089, and accepted the offer, though with great reluctance and with the condition that the king of England, William Rufus, should acknowledge Pope Urban in opposition to the antipope Clement, which the king ultimately consented to do. In 1097, a new difficulty having arisen between Anselm and William, the former set out for Rome to consult with the Pope. Urban received him with great distinction, but did not venture to declare himself on the side of the prelate in his dispute with the king. Meanwhile William had seized on the revenues of the see of Canterbury, which

he retained till his death in 1100. Anselm accordingly remained abroad, where he wrote his celebrated treatise on the atonement, 'Cur Deus Homo.' When William Rufus was succeeded by Henry I., Anselm was recalled. His canonization seems to have taken place in 1494. All the works of Anselm are directed toward founding a reasoned system of Christian truth. Such a system he considered to be a legitimate demand of reason, although he repeats again and again the doctrine that faith is necessary to the intelligence of the Christian mysteries, that the teaching of revelation must first be accepted by faith and afterward shown to have the support of reason. His celebrated ontological proof of the existence of God is to be found in the 'Proslogion.' The 'Cur Deus Homo,' treating, as already mentioned, of the atonement, is the most important of Anselm's works. In order to satisfy the reason of the need of an atonement and of the efficacy of the particular atonement that the Christian religion represents as having been made in the death of Christ, Anselm endeavors to establish the following positions: First, that God's honor is wounded by sin and his justice therefore requires satisfaction; second, that this satisfaction can be given only through one who is at once God and man; and third, that the voluntary death of Christ actually accomplished this satisfaction. The works of Anselm have often been published. The last complete edition forms the 155th volume of Abbé Migne's 'Patrologiæ Cursus Completus.' Among the numerous separate editions of the 'Cur Deus Homo' may be mentioned those of Lämmer (Berlin 1857) and Fritzsche (Zürich 1868). Anselm's personal character, distinguished by single-mindedness, gentleness, large-heartedness, and piety, makes him one of the brightest ornaments of the Christian Church.

Bibliography.— Eadmer, 'Vita Anselmi'; the works of Franck (1842); Hasse (1843–52); Rémusat (1853); R. W. Church (1870); Rigg (1896); and Welch (1900).

An'seres (Lat. nom. plur. of *anser*, goose), an order of water-birds, chiefly marked by the series of tooth-like projections on the edges of both mandibles, so placed that those on the upper mandible fit into the spaces between those on the lower when the mandibles are closed. Ducks, geese, and swans (qq.v.) belong in this order, and some classifications also include the screamers. They live and breed near the water, are found in all parts of the world, and are usually of large size. As a rule, they are swimming-birds and their numerous young need but little care. About 200 species are known.

An'son, George, Lord, a celebrated English navigator: b. Shugborough, 23 April 1697; d. Moor Park, 6 June 1762. He entered the navy at an early age and became a captain in 1724. In 1740 he was made commander of a fleet sent to the South Sea, directed against the trade and colonies of Spain. The expedition consisted of five men-of-war and three smaller vessels, which carried 1,400 men. After much suffering and many stirring adventures he reached the coast of Peru, made several prizes, and captured and burned the city of Paita. His squadron was now reduced to one ship, the Centurion, but with it he took the Spanish treasure galleon from Acapulco, arriving in England in 1744, with treasure to the amount of £500,000, after having circumnavigated the globe. His adventures and discoveries are described in the well-known Anson's 'Voyage,' compiled from materials furnished by Anson. His victory over the French admiral Jonquière, near Cape Finisterre in 1747, raised him to the peerage with the title of Lord Anson, Baron of Soberton. Four years afterward he was made first lord of the admiralty. In 1758 he commanded the fleet before Brest, protected the landing of the British at St. Malo, Cherbourg, etc., and received the repulsed troops into his vessels.

Anso'nia, Conn., a city of New Haven County, situated on the Naugatuck River, a few miles above its junction with the Housatonic, and on the New York, N. H. & H. R.R., being also the terminus of the New Haven and Derby branch. Two newspapers are published here, and the city contains two banks, many stores, public buildings, etc., besides extensive manufactories of brass and copper goods, clocks and clock equipments, movements, etc., electrical supplies, flour, lumber, and lumber products, foundries, and machine shops, etc. It was formerly a part of Derby, and received its city charter from the legislature in 1892. Pop. (1900) 12,681.

An'swer, in law, a defense in writing, made by a defendant to charges contained in a complaint filed by the plaintiff against him in a court of law. In all the code States a statute similar in its provisions to § 500 of the New York Code of Civil Procedure has been adopted. This section provides that the answer of the defendant must contain: (1) a general or specific denial of each material allegation of the complaint controverted by the defendant, or of any knowledge or information thereof sufficient to form a belief; (2) a statement of any new matter constituting a defense or counterclaim, in ordinary and concise language, without repetition.

Ant, a small social insect of the family of *Hymenoptera,* characterized by unusual distinctness of the three regions of the body, head, thorax, and abdomen, and by the stack or petiole of the abdomen having either one or (rarely) two "scales" or "nodes," so that the abdomen moves very freely on the trunk or thorax. The antennæ are elbowed as in wasps and bees. Ants live in societies, consisting, besides the males and females, of smaller wingless workers. In all ants except the *Odontomachidæ* and *Dorylidæ* the mandibles are wide apart at their base or insertion, so that they can be used without the other appendages of the mouth being opened or even moved. Both males and females are winged, but the males are much smaller than the females, while the wingless workers are smaller than the males. In these wingless forms the segments of the thorax become more or less separated, making the body much longer and slenderer, and less compact than in the winged normal sexual forms, the prothorax being more developed than in the males and females. The workers often consist of two forms: one with a large cubical head, or worker major, sometimes called a soldier, and the usual small-headed

form, or worker minor. In certain genera this polymorphism (q.v.) is still more marked. The legs are usually long and slender, the tarsi are five-jointed as usual in *Hymenoptera,* but the front or basal joint is disproportionately long, so that it functions as if part of the tibia; the tibias of the fore pair of legs are furnished with comb for cleaning the antennæ and mouth appendages. A sting is sometimes present, as in the *Poneridæ,* which sting like wasps and bees, and in the *Myrmicinæ,* while in the workers of ordinary ants it is either vestigial or entirely wanting. Some ants secrete an active poison (formic acid), which they inject into the wound made by their jaws in biting. In the *Formicinæ,* whose sting is atrophied, the amount of poison secreted is "relatively enormous" (Janet). Our *Formica obscuripes* is a very ferocious species, and, like the European *F. pratensis,* rises upon its hind legs, curves the abdomen, and ejects its venom, while Muckermann adds that the ejection of formic acid is so copious as to enforce the observer to momentarily retire.

The larvæ of ants are uniformly maggot-like, being legless, soft bodied, cylindrical, and with a small head bent on the breast. They are helpless and are fed by the workers.

Wheeler has shown that different species of ants employ very different methods of feeding their larvæ. Some (those of *Camponotus, Formica, Lasius,* and *Myrmica*) feed their young with liquid food regurgitated from their crops, and possibly also with the secretion of the salivary glands. Other species, however, *Ponerinæ* and some *Myrmicinæ,* feed their larvæ with comminuted insects. Wheeler states that the larvæ of certain ants "are not only able to subsist on solid food, but even on food of a vegetable nature."

The larvæ of the stingless genera usually spin a delicate silken cocoon, while those of the aculeate genera do not. Within the cocoon the larva transforms into the pupa.

Nesting Habits.— The history of a formicarium, or ants' nest, is as follows: The workers only (but in some species the winged ants) hibernate, and are found early in spring taking care of the eggs and larvæ produced by the autumnal brood of females. Every ant colony is founded by a single fertilized female. In the course of the summer the adult forms are developed, swarming on a hot, sultry day. The small yellow ants, abundant in paths and about houses in New England, generally swarm on the afternoon of some hot day in the first week of September, when the air is filled toward sunset with myriads of them. The females, after their marriage flight in the air, may then be seen entering the ground to lay their eggs for new colonies, or they are often seized by the workers and retained in the old colonies. Having no more use for their wings, they pluck them off, and may be seen running about wingless. The female, after laying her eggs, does not go abroad in search of food, but feeds the young larvæ with food regurgitated from her stomach and derived from her fat-bodies; thus the larvæ are poorly fed and become workers.

Nests.— The nests of some species of *Formica* are six feet in diameter and contain many thousand individuals. Ants also build nests of clay or mud and inhabit hollow trees. Ants in Europe build true mounds, sometimes three feet high, but in North America they are mostly subterranean, though in Wisconsin one ant (*F. obscuripes*) erects a true mound about 20 inches high.

Formica sanguinea is one of our most abundant species, making hillocks of sand or clay, according to the nature of the ground. From the formicary walks and underground galleries radiate in a labyrinth in all directions; and deep down, where the soil is perpetually moist, the galleries descend to a relatively greater depth than in Europe. Packard has found a variety of this species in Labrador, where it is common. It does not throw up hillocks, but tunnels in the earth. The nest of *Œcophylla smaragdina* is formed by drawing together a number of green leaves, which are united with a fine web. Some nests are a foot in diameter. This species swarms in hilly forests in New Guinea. Its sting is not very severe.

It is in argillaceous countries especially that the Œcodomas build their enormous formicaries, so that one perceives them from afar by the projection which they form above the level of the soil, as well as by the absence of vegetation in their immediate neighborhood. These nests occupy a surface of many square metres, and their depth varies from one to two metres. Very many openings, of a diameter of about one to three inches, are contrived from the exterior, and conduct to the inner cavities which serve as storehouses for the eggs and larvæ. The central part of the nest forms a sort of funnel, designed for the drainage of water, from which, in a country where the rains are often abundant, they could hardly escape without being entirely submerged if they did not provide some outlet for it.

The "agricultural ant" myth has been exploded by Wheeler, who shows that these ants do not plant grass seeds or "ant-rice" for a harvest. It is probable that Lincecum's error was due to the fact that the sprouted seeds stored up and then cast away as inedible take root and thus form a partial circle of tall grass around the nest.

Mushroom Gardens.— Möller has described what he calls "mushroom gardens" made by several South American species of *Atta.* The ants cut and bring the large pieces of leaves into their cellars, then cut them into smaller fragments, and finally comminute these still further till they form a flocculent greenish-brown pulp. This pulp is heaped up and soon becomes invaded by the mycelium of a fungus (*Rozites gongylophora*). The mycelium is kept aseptically clean — that is, free from all other species of fungi and even from bacteria — and induced to grow in an abnormal way by bringing forth minute swellings which constitute the only food of the ant colony. Möller likens these swellings to the *kohlrabi* of the German kitchen gardens.

Forel has studied the habits of two other species (*Atta cephalotes* and *A. sexdens*) in Colombia, in relation to this process of collecting and comminuting the leaves and in cultivating the mushroom. He has found that the largest workers (soldiers) triturate the leaves and defend the nest. They draw blood when they fight. The indigenes are said to use these insects for closing wounds. They induce them to bite the two lips of the wound, and thereupon sever the bodies from the heads, which then serve as a suture. The medium-sized workers cut the leaves from the trees, while in the nest the workers of the

ANTS.

Middle Section:—A. Honey Ant (Myrmecocystus Mexicanus). B. March of the Leaf-Carrying Ant (Œcodoma cephalotes).

Lower Section:—4. Yellow Ants (Lasius flavus), with Root Lice; highly magnified.

minim caste are forever clipping the threads of the mycelium of the *Rozites*, which then develops the *kohlrabi* on which the ants feed.

Wheeler has more recently excavated a large nest of leaf-cutting ants (*Atta ferrens*) in a piece of woodland in Texas. The large burrows, nearly an inch in diameter, were found to extend down to a depth of from three to five feet, and to open into large chambers, some of which were fully ten inches across and five to eight inches high. A few of these chambers were traversed by the roots of a large cedar, in the shade of which the ants had dug their formicary. Mushroom gardens were found heaped upon the floor, or, more rarely, enveloping, as aërial or «hanging» gardens, the roots that extended across the chambers.

The shape of a mushroom garden is that of a discoidal sponge. On its upper surface the ants pile up the flocculent vegetable débris, threaded in all directions with fungus hyphæ, in the form of thin, vertical, anastomosing plates, so that as much surface as possible is exposed to the atmosphere of the chamber. This atmosphere must contain a great amount of carbon-dioxid and a very small amount of oxygen. The ants leave several tubular or funnel-shaped openings, varying in diameter, and extending down into some chambers excavated in the base of the vegetable mass. In these chambers lives the huge queen of the colony (an insect nearly an inch long), the newly-fledged males and virgin queens, together with the larvæ, pupæ, and attendant ants. The whole mushroom garden swarms with workers representing all the different castes so characteristic of the genus *Atta*. The big-headed soldiers stalk about slowly over the surface of the comb, descending from time to time into the interior, as if to make sure that the great family is properly attending to its multifarious occupations, while thousands of *minims* keep moving about through the meshes of the mycelium, weeding the garden.

Relation of Quality and Quantity of Food to the Production of the Sexless Workers.— As is obvious, since the workers rarely lay eggs, the worker caste is not inherited either directly or collaterally from the parents. The view now suggested, and supported by a considerable body of facts, is that the larvæ on hatching are at first all alike, and that those which become workers are fed with different as well as less food than those which develop into sexual individuals. We know that the differences between the queen and the worker bees are due to differences in the nature of the food. The worker white ants have been found by Grassi to be the result of having different food and less of it than the males or females. Wasmann believes that the large workers of *Polyergus rufescens* («ergatoid females») are produced by the slave ants (*Formica fusca*), living in the colony, through excessive care and feeding of certain larvæ,— that is, that the *fusca* workers or slaves attempt to change worker larvæ of *Polyergus* into queens, but succeed only in producing the wingless ergatoids. Emery also holds that the sexual polymorphism of the ant colony is the result of the development of an instinct in the workers to feed the larvæ in different ways, and thus the characters in which the worker differs from the corresponding sexual forms are not congenital but acquired.

As has been said, the female ant, on founding a new colony, herself lives and nourishes the freshly-hatched larvæ with food from her stomach, ultimately from the fat-body. Hence these larvæ of the first brood are poorly fed and become small or dwarf workers (micro-ergates). These workers leave the nest and bring in food to their half-starved parent. Thus fed she becomes more prolific, lays another batch of eggs, and the larvæ become larger, and finally change into larger-sized workers. The colony thus becomes more populous and, as Wheeler states, the workers of successive broods grow larger until they attain the full stature of the species. Then and not till then do the workers bring up the males and queens, which are carefully herded, fed, and groomed by the workers until ready for the marriage flight. In some species of ants the males and virgin queens do not appear till the second or third year after the colony is founded. In a few American species of the huge cosmopolitan genus *Pheidole*, Wheeler and others find that the large-headed and small-headed or dwarf workers, are connected by a perfect series of intermediate forms, and this is due to the varying quantity of food. After an unfavorable season (autumn and winter) of drought and cold the number of *Pheidole* soldiers was unusually small. Thus Grassi's view as to the origin of the polymorphic forms in the termites being dependent on the quality and quantity is borne out by recent observations on ants.

Polymorphism and Variability of Ant Castes. — No solitary ants are known to exist, in all besides the males and females there are workers, and this is the direct result of their social mode of life. In our common species there is only one kind of worker, those in which the head is of uniform size, no big-headed ones or soldiers. But in ants collectively, though not in any one genus, there may be eight sets of individuals,— that is, ordinary males and «ergatoid» males, ordinary females and ergatoid fertile females, and exceptionally (*Formica rufa*), a set intermediate between the female and worker; there are also soldiers, worker-majors, and one or more kinds of worker-minors. The adult, sexually capable, though wingless forms, are called by Forel «ergatoids» from their resemblance to workers (Ἐργατης, a worker), this term is applied to both sexes. The worker females differ from the normal-winged female in the lack of a *receptaculum seminis*. The greatest number of castes in any one genus is five, occurring in *Eciton*, *Cryptocerus*.

Wheeler shows that polymorphism and variability depends on the amount and nature of the food and the increase in the population of the colony, and on the care and protection afforded to the reproductive individuals of the colony. There is, on the other hand, little variation in colonies which are poorly fed, and therefore unable to increase rapidly in number.

Primitive Ants.— Two primitive subfamilies of ants, the *Dorylinæ* and *Ponerinæ*, appear to have been evolved from a still more primitive and ancestral group, the *Cerapachynæ*, which Wheeler with good reason claims to be «the most archaic and generalized of existing *Formicidæ*. This group, species of which occur in Africa, southeastern Asia, Australia, and the southwestern United States (Texas) is repre-

sented in this country by *Cerapachys,* which mines the ground for a few inches under stones. The colony appears to be unusually small, the queen is wingless and the workers quite blind, and its life appears to be wholly subterranean, yet possesses senses of contact, odor (judging by the thick antennæ), and of hearing (it has "a beautifully developed stridulatory apparatus, which occupies the whole of the large membrane between the postpetiolar and first gastric segment") (Wheeler). This form, as Emery points out, seems to be the nearest of any ants to the *Mutillidæ,* especially the genus *Apterogyna,* which has an ant-like pedicel to the abdomen, and also resembles the ants in other features. That this group is also a very primitive one is shown by the plastic forms of females, of which there are four kinds, significant, as Wheeler remarks, "as the phyletic source to which the different female forms of all the subfamilies of ants are to be traced."

Slavery.— This phase of social life is not infrequent among ants, and it reacts upon the slaveholders by rendering them helpless. *Formica sanguinea* has been observed in Europe by P. Huber to go on slave-hunting expeditions. They attack a "negro colony" belonging to a smaller black species, pillaging the nests and carrying off merely the larvæ and pupæ. The victors educate them in their own nests, and on arriving at maturity the negroes take the entire care of the colony. *Polyergus rufescens* is also a slave-making ant, and Latreille very justly observes that it is physically impossible for the rufescent ants (*P. rufescens*), on account of the form of their jaws, and the accessory parts of their mouths, either to prepare habitations for their family, to procure food, or to feed them. *Formica sanguinea* sallies forth in immensely long columns to attack the negro ant. Huber states that only five or six of these forays are made within a period of a month, at other seasons they remain at peace. Huber found that the slave-making *Polyergus rufescens,* when left to themselves, perish from pure laziness. They are waited upon and fed by their slaves, and when they are taken away their masters perish miserably. Sometimes they are known to labor, and were once observed to carry their slaves to a spot chosen for a nest. The *Formica sanguinea* are not so helpless; they assist their negroes in the construction of their nests, they collect their sweet fluid from the *Aphides;* and one of their most usual occupations is to lie in wait for a small species of ant on which they feed; and when their nest is menaced by an enemy they show their value of these faithful servants by carrying them down into the lowest apartments, as to a place of the greatest security. Pupæ of both the slave-making species were placed in the same formicary by Huber, where they were reared by the "negroes," and on arriving at maturity lived together under the same roof in the most perfect amity. Darwin states that in England *Formica sanguinea* does not enslave other species.

In this country forays of a colony of *Formica sanguinea* upon a colony of a black species of *Formica,* for the purpose of making slaves of them, has been not infrequently observed. Slavery (*duloris*) is known to exist only between ants belonging to the same subfamily, the species of only four genera being known to practise slavery. In Europe the "paragon of dulotic ants" is *Polyergus rufescens,* or the "amazon" ant, as the workers are very warlike, though they are in other respects helpless and completely dependent on their slaves, dying of starvation if deprived of them. Darwin's explanation of the origin of the slave-making habits is that they were originally due to the predatory instincts of ants in general, seen in their carrying off the pupæ of other species, which, becoming stored as food, and, finally developing, would in their new abode do what work they could; and this habit of collecting pupæ for food might be rendered permanent for the purpose of raising slaves.

Sound Produced by Ants.— Certain species of ants are evidently not deaf, because capable of producing sounds which must be heard by others of their own kind. Thus *Myrmica rubra* has a sound-producing apparatus, a strigil, or file on the seventh abdominal segment (Janet); another ant of this group (*Sima læviceps*) is provided with a stridulating file; and in the ronerids there is a stridulating organ consisting of a band of very fine raised lines on the second segment behind the node. Other ants (*Polyrhachis*) tap on the surface of a leaf with their heads, producing a sound audible to human ears, as does an Assamese species by scraping the end of its abdomen on the dry leaves of its nest.

Senses of Ants.— While ants may be blind and deaf, none are known to be destitute of the sense of smell. The olfactory organs are little sensory pits in the antennæ. It is undoubtedly by means of their sense of smell that ants recognize the members of their own nest, and those of other species which they treat as enemies. It is probably by this means that they distinguish their friends from their enemies. Thus the cause may be the result of reflex action, rather than any special degree or kind of intelligence.

Parasitic Ants with No Workers.— Such are the ants of the genera *Anergates* and *Epœcus;* in the former the male and females are helpless, incapable of leaving the nest, and dependent on the attentions of the workers of another genus (*Tetramorium*) which live with them. This strange relationship seems thus far inexplicable.

Symbiosis in Ants.— The relation between ants and plants is very intimate, and it assumes different phases. See SYMBIOSIS.

Commensalism.— Ants' nests are so many apartment or boarding hives. A vast number of beetles, aphides, cockroaches, flies, and arachnids take up their abode in the nests of ants, where they are allowed by their willing or unwilling hosts to feed on the excretions of the ants themselves or their food. The fostering instincts of ants thus seem to be extended in various degrees to their guests and thus lay the foundation for this semi-parasitic community. Upward of 1,500 species of *Arthropoda* are known to live in more or less cordial relations with their hosts.

A. S. Packard,
Late Prof. Zoology, Brown University.

Antacid, ănt'ăs-ĭd, an alkali, or any remedy for acidity in the stomach. Dyspepsia and diarrhœa are the diseases in which antacids are chiefly employed. The principal antacids in use are magnesia, lime, and their carbonates, and the carbonates of potash and soda.

Antæus, ăn-tē'ŭs, the giant son of Poseidon (Neptune), and Gē (the earth), who was invincible so long as he was in contact with the earth. But Heracles (Hercules), whom he challenged to combat, perceiving the secret of his strength, lifted him in the air and strangled him.

Antal'cidas, a Spartan statesman, chiefly known by the celebrated treaty he concluded with Persia at the close of the Corinthian war in 387 B.C. The peace which followed was styled "The Peace of Antalcidas."

Antali'kali, any substance which neutralizes an alkali, used medicinally to counteract an alkaline tendency in the system. All true acids have this power.

Antananarivo, ăn'tă-nä'nă-rē-vō, or Tananarivo, the former capital of Madagascar, situated in the province of Imérina. In recent years it has been almost entirely rebuilt, its old timber dwellings having been replaced by buildings of sun-dried brick on European models. It contains two royal palaces, immense timber structures, one of which is surrounded with a massive stone veranda with lofty corner towers. It has manufactures of metal work, cutlery, silk, etc., and exports sugar, soap, and oil. Pop. about 100,000, of which but few are Europeans. See Madagascar.

Antar, ăn'tär, or **Antara,** ăn'tă-ra, an Arabian warrior and poet of the 6th century, author of one of the seven Moallakas hung up in the Kaaba at Mecca, and the hero of a romance analogous in Arabic literature to the Arthurian legend of the English. This romance, which has been called the 'Iliad of the Desert,' is composed in rhythmic prose interspersed with fragments of verse, many of which are attributed to Antar himself, and has been generally ascribed to Asmai (b. 740 A.D.; d. about 830 A.D.), preceptor to Harun al-Raschid. See Hamilton's 'Antar: a Bedouin Romance' (1820).

Ant'arc'tic Regions, the name given to part of the earth's surface surrounding the South Pole. Its limits are variously defined by geographers; some consider it to be co-extensive with the Antarctic Ocean, which in a strict sense is bounded by the Antarctic Circle, while others include also that portion of the great Southern Ocean affected by Antarctic influences. According to the latter interpretation the region is approximately defined by the northern limit of the drifting pack-ice or about lat. 60° S., although icebergs are sometimes encountered as far north as lat. 45° S. The Antarctic region is surrounded by a great expanse of shoreless water which further north is divided by the continental lands into the Atlantic, Pacific, and Indian Oceans. The area comprised within the Antarctic Circle is about 8,200,000 square miles.

Exploration.— The early explorations into the region south of the equator and the discovery of numerous lands gave rise to the belief that a vast continent existed near the South Pole. The first voyage of Capt. Cook in 1769 showed, however, that New Zealand, contrary to the general opinion, was an island, and in his second voyage, in 1772, it was proved that the continent, if it existed, did not extend beyond the Antarctic Circle. In 1773 Cook sailed south again and the following year reached lat. 71° 10′ S. in lon. 106° 54′ W., where he was prevented from advancing further by enormous ice-floes. No land was seen on this voyage, although its presence was indicated by flights of birds. In 1819 Capt. Smith rounded Cape Horn and sighted the South Shetland Islands, while in the following year Alexander Land still farther south was discovered by Bellingshausen. Morrell, an English explorer, sailing in 1822, visited the Falkland Islands, Bouvet Islands, and South Georgia, and reported that he found the temperature of both air and water to be milder the farther he advanced southward. Biscoe circumnavigated the southern ice region in 1831–2, penetrating beyond lat. 67° S.; he discovered Enderby Land and its southwestern extension, which he named Graham Land. Kemp sighted and marked Kemp Land in 1833. The Balleny Islands were discovered by Balleny in 1839, and D'Urville, in 1839–40, made a long voyage, during which he visited many of the previously discovered lands, changing their names to make room for selections of his own. The latter also found Adélie Land, an immense tract situated far south of New Zealand and stretching for an unknown distance toward the Pole. The voyages of Wilkes (1838–42) and of Ross (1841–42) were of great importance, especially in their scientific aspects. Ross encountered land in 70° 41′ S. lat., 172° 30′ E. lon., which had a steep, rocky coast-line; farther south in 77° 32′ S. lat. he found a lofty, active volcano which he named Mt. Erebus and an inactive cone called Mt. Terror. He sailed for a distance of 450 miles along an unbroken ice barrier rising 150 feet above the water. During the next 30 years little was added to our knowledge of the Antarctic region. Dallman in 1873–4, however, visited many of the localities marked by previous explorers, and was able to confirm their reports. The Challenger expedition, which started out in 1874, returned with proof of a floating ice barrier and also accomplished a vast amount of oceanographic investigation. More recently the expedition of Gerlache, who penetrated to lat. 71° 36′ S., was fruitful in scientific results and added over 100 islands to the list of those previously known. Borchgrevink, a Norwegian, in charge of an English expedition, passed the winter of 1898–9 in the Antarctic and in the following summer reached lat. 78° 50′ S., the farthest then attained. In 1900 he set out again and succeeded in locating the south magnetic pole in

lat. 73° 20′ S., lon. 140° E. Three expeditions were fitted out in 1901 with a view of testing the theory of an antarctic continent; they are in charge of Scott (English), Von Drygalski (German), and Nordenskjöld (Norwegian). In March 1903 a vessel sent to relieve Capt. Scott's party returned to Auckland, N. Z., and reported that Capt. Scott had reached lat. 82° 17′; lon. 163°,— thus penetrating the farthest south recorded. See POLAR RESEARCH.

Antarctic Ocean.— The depths of the Antarctic Ocean have been explored in various parts by Ross, Wilkes, Nares (Challenger expedition), and Gerlache. Ross sounded in 4,000 fathoms in the vicinity of South Georgia without reaching bottom. The Challenger found depths of from 1,300 to 1,950 fathoms near the Antarctic Circle, south of Australia, while farther north the soundings ranged from 950 to 2,600 fathoms. Between the Cape of Good Hope and Kerguelen Islands depths of 2,500 to 3,100 fathoms have been reported. There seems to be a gradual shoaling of the waters toward the pole, for Wilkes sounded in 500 to 800 fathoms off Adélie Land and in 100 to 500 fathoms off Victoria Land, while Gerlache recorded less than 200 fathoms west of Palmer Land. The bottom in the extreme south is covered with a layer of diatom ooze composed of the frustules of diatoms which lived near the surface, together with shells of pelagic organisms and débris dropped by the floating ice. The diatom ooze has a chalky appearance when dried and is white or yellowish-white in color. Farther northward the bottom is covered with deposits of globigerina ooze made up of the casts of *Foraminifera,* and in still deeper water the characteristic red clay, found at great depths in all the oceans, occurs. The temperature of the surface waters of the ocean range from a few degrees below to a few degrees above the freezing point. Ross reported an average of 29.8° F. south of 63°, with extremes of 27.3° and 33.6°, and the Challenger found a temperature of 29° F. at 65° S. In the deepest water the temperature ranges from 32° to 35°, or about the same as is found elsewhere in the deep ocean.

Antarctic Continent.— The question whether there is a large land area of continental character within the Antarctic Circle has not yet been definitely settled, although most geographers and explorers express an affirmative opinion based upon strong evidence. In the first place land areas of indefinite extent have been sighted by Wilkes, D'Urville, Ross, Kemp, Bellingshausen, and others, and these areas together form an interrupted ring about the Pole. The mountain ranges and peaks discovered by Ross in Victoria Land are apparently of continental character, being composed of ancient crystalline rocks and rising from 7,000 to 15,000 feet above the sea. Granite and gneiss were found by D'Urville near Adélie Land, and Borchgrevink states that the rock at Cape Adare is mica-schist; these are distinctly continental types. Indirect evidence is furnished by the materials transported from the far south by the icebergs. Sandstone, basalt, and boulders of massive rocks were found by Wilkes on the ice, and the Challenger returned with fragments of gneiss, granite, diorite, and sedimentary rocks which had been dredged from the floor of the ocean. In addition fossil wood and shells of mollusks closely resembling forms found in the Tertiary rocks of Patagonia were discovered on Seymour Island. The great icebergs which drift far into the region of the Southern Ocean are difficult to account for on any other theory than that they have been broken off from a vast sheet of land ice like that covering Greenland. The meteorological phenomena, especially the system of winds prevailing within the Antarctic Circle, indicate continental land about the Pole. If it is assumed that Alexander Land, Victoria Land, Graham Land, Enderby Land, and other lands sighted by explorers represent the borders of the continent, its area would amount to approximately 4,000,000 square miles or about one half of the region comprised within the Antarctic Circle.

Antarctic Ice.— The conditions of ice formation in the Antarctic differ materially from those of the Arctic region. In the northern hemisphere the polar ocean is enclosed by land, so that sea ice is much more important than land ice, the latter occurring only on the edge of the area, while in the Antarctic the reverse is true. Enormous masses of floating ice, flat-topped with perpendicular walls and oftentimes measuring many miles in width and length, are found throughout the Antarctic Ocean. Wilkes and Bruce encountered icebergs 3 to 90 miles in length, extending 200 feet above the water and about 1,800 feet below, or about 2,000 feet thick. The newly formed bergs exhibit a parallel structure marked by the alternation of strata of snow-white and cobalt-blue ice in horizontal planes. They have evidently been broken off from the edge of a thick ice-cap covering the Antarctic lands and gradually pushed over the surface toward the sea. The thickness of the ice near the Pole is estimated by Croll upon theoretical grounds at from 12 to 14 miles, but such an enormous depth of ice seems hardly probable. Off the coast of Victoria Land the ice-wall is only 10 to 20 feet high.

Climate.— The climatic conditions of the Antarctic are imperfectly understood, but as regards temperature they may be characterized as extremely severe. Compared with the Arctic the region is placed at a disadvantage in having its summer during perihelion and winter in aphelion. Observations made by Ross in the vicinity of Victoria Land from 60° to 78° S. showed a mean summer temperature of 28.85° F. for the sea and 28.31° for air; in lat. 66° 29′ S. the maximum temperature in the month of December was 45.52° F. Wilkes found the mean temperature for January and February near Wilkes Land to be 30.2° F., with extremes of 34.52° and 23°, while Gerlache reported a winter minimum in 71° 30′ S. of —45°. The German station in South Georgia gave a mean temperature of 37.52°. The glaciation of the land areas, the great ice-floes, and the saturated condition of the atmosphere producing heavy fogs, are influential in producing the extreme cold. Barometric observations by Ross indicate a gradual increase in pressure south of 75° S., and it is believed that an area of extreme high pressure exists around the Pole, producing a permanent anticyclone with winds blowing in a southeasterly direction toward the higher latitudes. No estimate of the precipitation has been made, but the atmosphere is probably comparatively dry over the land areas in the extreme south and the precipitation is in the form of fine ice crystals. Farther north there is a

SOUTH POLAR REGIONS

heavy precipitation of snow and sleet; rain seldom falls within the ice-bound region.

Fauna and Flora.— The largest of the Antarctic mammals are the whales which frequent the cold waters in great numbers. Many of the species are similar to if not identical with those inhabiting the Arctic seas; rorquals, humpback whales, pilot whales, grampuses, and dolphins are known, also a small whalebone whale (*Balæna australis*), but the right whale does not exist in the Antarctic. There are 13 species of seals, including four of fur seals, which are closely related to those found in the North Pacific, the sea-lion and the sea-elephant. Among birds the penguins are most abundant, their rookeries being found on the borders of all lands free from ice. The largest species is the king penguin: a specimen captured by Wilkes measured 4 feet 6 inches in height and weighed 65 pounds. A gull-plover (*Chionis*) is found exclusively in the Antarctic. A small teal frequents Kerguelen, and stormy petrels, albatrosses, gulls, skuas, and terns breed on most of the islands. Borchgrevink found 11 species of fish in Antarctic waters, most of them new to science. Explorers have usually reported that fishes were scarce. A few species of insects have been described by Arctowski and Borchgrevink. It is believed that no land animals exist in the extreme south. Of plant and invertebrate life inhabiting the Antarctic Ocean there is a great abundance. The pelagic animals include cephalopods, brachiopods, and gastropods, which furnish food for the whales, cœlenterates, and *Protozoa*. The deep-sea fauna is much more strongly developed than the shallow-water fauna living in the vicinity of the Antarctic lands. Thirteen species of phanerogamous and numerous cryptogamous plants have been found near South Georgia. Hooker obtained from Cockburn Island four species of marine algæ, three of fresh-water plants, and twelve land plants, the last-named mostly lichens and mosses.

Antares, ăn-tā'rēz («corresponding to Ares» or Mars, because assumed to be like Mars in color), or *Alpha Scorpii*, a red double star of the first magnitude, the middle one of three in the body of the constellation Scorpio; much used by sailors in ascertaining longitude.

Ant'-bear', the great ant-eater, or tamanoir. See ANT-EATER.

Ant'-birds', a general term applicable to members of certain groups of birds within the *Formicariidæ* (q.v.), a South American group, all of which subsist largely upon ants. They have no proper oscine or singing organs, yet some of them have clear musical voices, and their notes of excitement when following the moving columns of destructive tropical ants, feeding not only upon them, but upon the insects they put to flight, are a warning which the natives understand and heed. All these birds are small and long-billed. The sub-family *Thamnophilinæ* is made up of the «ant-shrikes.» The «ant-wrens» belong to the sub-family *Formicivorinæ;* and the «ant-thrushes» are a species of the *Formicariinæ*, a typical sub-family. The pitta (q.v.) is also sometimes improperly called an «ant-thrush.»

Ant'-eat'er, a name given to several quite different mammals, but particularly applied to the *Myrmecophagidæ*, a South American family of *Edentata*, with the head extremely long; the snout slender; the mouth, ears, and eyes small; the tongue, long, cylindrical, and covered with a viscid saliva which holds whatever insects are licked up until the tongue can be withdrawn into the mouth. When not in use the tongue lies doubled up in the mouth. The legs are strong and heavy; the toes vary in number in the different species, but in all species are united as far as the base of the large claws, which are adapted to digging, but are turned under the feet when the animal walks. The great ant-eater, or ant-bear (*Myrmecophaga jubata*), found in tropical South America, is a sluggish animal, forest-dwelling, but entirely terrestrial; it grows to a height of two feet and a length of four feet, not including its long and very shaggy tail, which is often carried turned over its back like an umbrella. Though timid, it is capable of effective self-defense, using its strong fore-arms to hug and tear its opponents. Its body color is gray, set off by a black band which crosses the breast and tapers to the top of the shoulders, and by white feet and fore-legs. The hair is long, particularly on the back toward the tail, and on the tail itself. It is very unsocial, spending much time asleep, curled up with its tail spread over it as a protection from sun or rain. As more than one is seldom produced at a birth, the great ant-eater is not numerous.

Another, much smaller, species (*Tamandua tetradactyla*), which is also tropical, is arboreal and has a prehensile tail. It is about the size of a cat; its head is broader in proportion than that of the great ant-eater; its hair is bristly and short, black on the body, yellowish white on the head, neck, fore-legs, and hind-quarters. A third species (*Cycloturus didactylus*), the little or two-toed ant-eater, is still smaller than the tamandua, and is also arboreal. Its claws are curved and very sharp for climbing, and its whole structure is peculiarly adapted for life in trees.

Besides the animals of this family, called the true ant-eaters, are their allies, the scaly ant-eaters, or Manids (see MANIS), the aard-vark, the porcupine ant-eaters (see ECHIDNA), and certain insectivorous marsupials found in Australia and belonging to the genus *Myrmecobius*. Certain birds, such as the *ant-shrike*, are also called ant-eaters. (See ANT-BIRDS.)

An'tedilu'vian («before the flood»), theologically referring to the period previous to the Deluge recorded in Genesis. Geologically a term now disused, meaning before the waters of the earth had transformed its surface into the present form by submergence, erosion, etc.

An'telope (Greek, *antholops*, a horned animal), a bovine animal of the group formerly called the family *Antilopidæ*, now placed as a subfamily between the cattle and the goats in the family *Bovidæ*. Its members are all short-haired, lightly and gracefully built, and carry their heads uplifted: in size they vary from that of a kid to the height of a tall horse, and almost all are timid and fleet-footed. Although no very definite external differences separate the antelopes from the other groups of the *Bovidæ*, they are easily recognized by these general characteristics. Popularly, the antelopes include such widely varying species as the goat antelopes (the chamois and the Rocky Mountain

goat) at one extreme, and at the other the American prong-horn (q.v.), which has branched deciduous horns; but scientifically both these extreme forms must be excluded, and the term confined to Asian and African species having horns present in both sexes, the cores of which are solid, and which tend to grow upward rather than outward. To these rules there are exceptions, however, and a scientific distinction of the group from the cattle, and still more from the sheep, is very difficult.

Antelopes have been pronounced the most generalized of the living *Bovidæ*, and consequently are regarded as representing the form from which the other types within the family have descended. Their earliest fossil remains are found in the Miocene, when they flourished all over Europe and Asia, and their migration into Africa seems to have been comparatively recent. When Africa was first explored by Europeans, however, they were established there and had so enormously multiplied as to be the chief resource for meat of the natives and of carnivorous animals. Colonization so wasted and scattered them, however, during the latter part of the 19th century, that some species are already extinct, and others would be except for preservation on private estates.

Antelopes may be ranged in certain groups, such as the antelopine gazelles, including many species which are beautiful in form but do not often exceed 30 inches in height, with goat-like teeth, hairy muzzles, and ringed horns, usually either spiral or lyre-shaped. This group inhabits deserts from the Cape of Good Hope to India, and among them are the ariel and other gazelles, the springbok, the blackbuck of India, the saiga, and various others. Another, the Cervicaprine group, contains the little African reedbuck, the small klipspringer and rehbok, the tiny steinbok, and the larger waterbucks, etc. A third group comprises several African forest-ranging species, among others the pygmy antelope, only 13 inches tall and the smallest known ruminant. Another group is far larger and has many of the characteristics of cattle, while still another section diverges toward the goats. The largest, most beautiful and valuable group of all is that which contains the Indian nilgai and the African bushbuck and eland.

There is an erroneous notion abroad that antelopes all live in large bands, or even vast herds, that roam over flat plains and perform migrations in large bodies from one place to another as scarcity of food and the weather compel them. Instead of this uniformity, however, there exists great variety in size, shape, color, speed, agility, and habits, in adaptation to the varied circumstances in which they live. Some dwell altogether in mountains and are as expert in climbing about the rocks as are the goats. Others frequent forests and rarely leave their shade. Still others remain entirely among hills where dense thickets cover the rough surface, and dart in and out among the bushes so rapidly and expertly that the sportsman finds the greatest difficulty in getting a shot at them. Aquatic antelopes exist, especially in South Africa, where certain kinds, as for example, the reedbucks, spend nearly all their time in marshes, wading and swimming about and feeding upon aquatic vegetation. It is indeed only the larger, stronger, and better-armed kinds that can endure existence in plains where they have little means of protection against leopards, lions, and other enemies, and must trust entirely to escape by flight or by being overlooked. The result has been the development among them of great speed, but this has not been accompanied by endurance, since few are required or are able to continue to run swiftly any great distance. As an aid to their safety, nature has developed in the desert- and plain-dwelling species an adaptation in color to their surroundings, making them almost invisible when lying down or standing against the rock and thicket. As a rule their coats have the dull colors of a plains landscape, the only somewhat conspicuous markings being those upon the face and tail, which serve the purpose of "recognition marks" but are not sufficiently large to attract attention at any great distance. Sometimes this protective color of antelopes is very striking, as in the case of the red hartbeest of East Africa, which frequents the open country where the soil is rust-red and termite hills are exceedingly numerous. It is said that the most experienced hunters are constantly deceived by the exact resemblance between one of these antelopes when lying down and an ant-hill.

The flesh of most antelopes is regarded as excellent food and some of them yield meat that is most delicate eating. The hides of the larger ones make good leather, and the destruction which has overtaken the race in South Africa has been brought about mainly by hide-hunters. The horns were put to many uses by the native Africans and Asiatics and are still in demand for the making of fancy handles and other articles of ornament.

For additional information see BLACKBUCK; GAZELLE; GNU; HARTBEEST, and other names of groups and species in this family.

An'tenna'ta, a name given by Lang to a group of tracheate arthropods embracing his sub-classes *Myriapoda* and *Hexapoda* (*Insecta*). Consult Lang, 'Text-book of Comparative Anatomy' (N. Y. 1891).

Anthol'ogy ("nosegay"), a name originally given to a collection of short unconnected Greek poems from many sources, and till lately applied only to that and its various enlargements. In recent times it has been extended to any collection of detached pieces of miscellaneous authorship, prose or verse, to represent a language, a literature, a country, an epoch, or any sort of subjective idea as a thread on which to group it. The most famous anthologies of the past are the following:

The Greek Anthology.— This originated in a class of poems, invented by the Greeks,— the epigram, properly meaning mere inscription, and used for epitaphs, votive offerings, or other commemorative occasions. The modern restriction of the term to mean "short pungent witticism" is due to the characteristics of the original epigram imposed by its uses,— brevity, pregnancy, singleness of idea, and purity of style. Any piece which fulfilled this idea was later called an epigram by the Greeks themselves. The species was thoroughly developed and cultivated by the Alexandrian school. Polemon, Alcetas, and others made collections of poems on special subjects; but about 80 or 90 B.C. Meleager of Gadara in Syria, a poet and rhetorician, for the first time made a comprehensive selection from all the best Greek poems in this genus from

Sappho down, 46 in all, besides contributing 130 of his own. He called it *Stephanos*, 'The Garland'; and so great were his taste and judgment that no other collection has ever averaged so high in quality. It was the "Golden Treasury" of Greece.

In the 1st century A.D. one Philip of Thessalonica enlarged Meleager's group by 13 new poets and called the whole 'The Anthology.' Not very long after, the sophist Diogenianus again supplemented it; and under Hadrian, Strato of Sardis made a new collection called the 'Muse of Love,'— a very earthly muse. Under Justinian and after, there was a revival of epigram-writing by a literary circle of whom Agathias the lawyer and Paulus the Silentiary (privy councilor) were the heads, and who did some very beautiful work of this kind; and Agathias made a fresh collection based on Meleager, called 'The Circle,' divided into books, and for the first time arranged by subject.

There were therefore five Greek anthologies at the beginning of the Middle Ages. About the beginning of the 10th century, apparently, a monk named Constantinus Cephalas made a fresh gathering from these and from the works of other epigrammatists which had been published separately, classifying it after Agathias' fashion. For much of his matter we are indebted to this collection solely, the originals or earlier editions having perished. Another monk, Maximus Planudes, made a further recension, rather by mutilating Cephalas' work than by new research; though he added some on works of art and some of his own of little value. His edition was first published at Florence in 1594, and was for nearly two centuries the only one known to the public; that by Cephalas discovered in 1606 not being published until 1772. From its being found in the Palatine Library at Heidelberg this MS. is usually known as the Palatine MS. It represents over 300 poets of all ages of Greece, and therefore all sides and aspects of Greek emotion and poetic art as well as intellectual observation and reflection, with the greatest brilliancy and beauty.

Through all the ups and down of Greek civilization this series of poems forms a living bond closely united with the feeling and spirit of each age. To read it has been justly compared to excavating an ancient city, where the strata succeed each other with scarcely perceptible change, but form a continuous history of its development. Dr. Garnett divides it into four stages: The Hellenic, of which Simonides is the most typical, characterized by the bona fide nature of the inscriptions (not mere literary exercises), simplicity, dignity, and transparency: the Alexandrian era, of which Callimachus stands first, when it was a play of the imagination, often anecdotal, sportive, amorous, or satirical,— much richer and more interesting, less pure and sincere; the Roman-Oriental, of which Meleager is the greatest, luxurious, gorgeous, fanciful; this passes later into the modern epigram, stinging satire and lampoon, or ethical reflection; and finally, the circle of Agathias or the Byzantine school, imitators, but of real power and originality, of genuine feeling and much ingenuity and elegance of style. Its effect on European literatures has been enormous; it has supplied them with imagery, filled them with expressions that are household words with us, been a model of style most beneficial in inculcating brevity, simplicity, and accuracy of language, and a treasure-house of information as to life.

The best of recent translators are, in verse, J. A. Symonds and Richard Garnett; in prose, J. W. Mackail.

The Latin Anthology.—A selection of Latin poems from Ennius to about 1000 A.D., was formed by Peter Burmann the younger in 1759. The Romans had nothing corresponding to the Greek Anthology, though collections of sententious thoughts were published, and individual poets like Martial wrote books of epigrams and published them. The great Scaliger in 1573 made a collection of Latin pieces, and Pitthœus another and larger one in 1594. These were added to by others from time to time; but Burmann edited them all into his 'Anthology of the Ancient Latin Epigrams and Poems.' In 1869 Alexander Riese brought out the first volume of a better edition of the Latin Anthology (2d ed. 1894), discarding Burmann's arrangement and placing the poems found in MSS. first, the inscriptions following in another volume. As these Latin anthologies had no literary purpose, being designed only to preserve all fragments good or bad, so they have slight literary value as wholes, the good pieces being swamped by grammarians' exercises and conceits of worthless writers. Being mostly of late date they are not nearly so valuable historically as the Greek. There are also Arabic, Persian, Turkish, and other anthologies, including several by authors of the United States.

An'thon, Charles, an American educator: b. in New York city, 17 Nov. 1797; d. there, 29 July 1867. He was graduated at Columbia College in 1815 and admitted to the bar 1819, but never practised. He was adjunct professor of Greek and Latin at Columbia 1820–30, and full professor and head master of the grammar school connected with the college 1830–64. In 1835, in connection with the Harper publishing house, he projected a 'Classical Series' to include works used in academies, preparatory schools, and colleges. It proved the most successful enterprise of its kind ever undertaken in America. Of the more than 50 volumes edited by Anthon the following are the best known: an edition of Lemprière's 'Classical Dictionary' (1822); 'Horace,' with notes (1830); 'Dictionary of Greek and Roman Antiquities' (1843); 'Classical Dictionary' (1841).

Anthony, ăn'tō-nĭ, **Clemens Theodor:** b. 1755; d. 1836. King of Saxony, who succeeded his brother Friedrich August I. 5 May 1827. The French revolutionary movement of 1830, spreading to Saxony, compelled him to grant a constitutional government in 1831.

Anthony, ăn'tōnĭ, **Henry Bowen,** an American legislator: b. in Coventry, R. I., 1815; d. 1889. He was graduated from Brown University in 1833 and was editor of the Providence *Journal* for over 20 years. He was governor of Rhode Island in 1849 and 1850, and United States Senator from 1859 till his death.

Anthony, ăn'tō-nĭ, **John Gould,** an American naturalist: b. in Providence, R. I., 17 May 1804; d. in Cambridge, Mass., 16 Oct. 1877. Leaving school at 12 years of age he followed a business career for 35 years. He early developed

a taste for natural history, and his publications attracted the attention of Agassiz, through whom in 1863 he became head of the conchological department of the Museum of Comparative Zoology, a post he held until his death. He was a recognized authority on the subject of American *Mollusca*.

Anthony of Padua, Saint: b. Lisbon 15 Aug. 1195; d. in Padua 13 June 1231. Shortly after his ordination to the priesthood he was deeply stirred by the recital of the cruel martyrdom of five Franciscan missionaries whose bodies had just been brought from Morocco to Coimbra, where Anthony was then living. Having entered the Franciscan order, he soon started for Africa in the hope of being permitted to die for Christ. He had scarcely landed when illness obliged him to leave. Hearing about the general council of his order which was going on, he started for Assisi, where he met Saint Francis, the founder of the order. His profound knowledge of sacred things, joined to his sanctity, caused him to be made the first teacher in the Franciscan order and later on the Provincial of all the convents of the order in upper Italy. His feast is celebrated June 13.

Bibliography.—Coleridge, S. J., 'Life and Works'; Meyer, 'Leben des H. Antonius'; Lepitre, 'Saint Anthony of Padua,' translated by E. Guest (1903).

Anthony, ăn'tō-nĭ, **Saint,** the patriarch of monastic institutions: b. near Heraclea, in Upper Egypt, 251 A.D.; d. 356. Giving up all his property, he retired to the desert, where he was followed by a number of disciples, who thus formed the first community of monks.

Anthony, ăn'tō-nĭ, **Saint, Cross of,** a cross in the shape of the letter T, often styled the Tau Cross. In heraldry the name is given to two stripes, a horizontal and a vertical one crossing in the middle of the escutcheon.

Anthony, ăn'tō-nĭ, **Saint, Falls of,** a noted fall in the Mississippi River, within the limits of Minneapolis, Minn. (q.v.). The entire descent of the stream for three quarters of a mile is 65 feet. The falls and surrounding scenery are exceedingly picturesque.

Anthony, ăn'tō-nĭ, **Saint, Fire of,** a name now applied to a form of erysipelas. A distemper of this character became epidemic in France in 1089. Many miraculous cures having been effected by the imputed intercession of Saint Anthony, the order of Canons Regular of Saint Anthony was founded the next year for the relief of those afflicted with this disease. The order continued to exist till 1790.

Anthony, Sister, American nurse and nun, known before entering religious life as Mary O'Connell: b. Limerick, Ireland, 15 Aug. 1815; d. Cumminsville, Cincinnati, Ohio, 18 Dec. 1897. She came with her parents to this country in childhood and in 1835 entered the order of Sisters of Charity at Emmittsburg, Md., removing to Cincinnati in 1837, there to take charge of work in Saint Peter's Orphan Asylum. On the establishment of Saint Joseph's Orphan Asylum at Cumminsville, in 1854, Sister Anthony was placed in charge and the next year she was transferred to Saint John's Hospital, where she remained 10 years. The terrible slaughter at the battle of Pittsburg Landing appealed so strongly to her sympathies that with two companions she accompanied the noted surgeon, George C. Blackman, to Nashville to minister to the wounded, there winning her title of "The Angel of the Battlefield." She returned to Cincinnati on a hospital steamer with many wounded soldiers whom she cared for at Saint John's Hospital. In 1866 two prominent Protestant business men of Cincinnati purchased the United States Marine Hospital and transferred it to the Sisters of Charity in the hands of Sister Anthony. The name was then changed to "The Good Samaritan," and she remained in charge till 1882. Not only was she in charge of various institutions of her order, but was several times procuratrix of the community. She is buried at the mother house of Mount Saint Joseph and her grave is annually strewn with flowers on Memorial Day by the soldiers of the Grand Army of the Republic.

THOMAS P. HART, M.D.,
Editor 'The Catholic Telegraph,' Cincinnati, O.

Anthony, Susan Brownell, American reformer: b. South Adams, Mass., 15 Feb. 1820; d. Rochester, N. Y., 13 Mar. 1906. She taught school in New York in 1835–50, in 1852 assisted in organizing the Woman's New York State Temperance Society, and in 1854–5 held conventions in each county in New York, in behalf of female suffrage. In 1857 she became a leader in the anti-slavery movement, and in 1858 advocated the co-education of the sexes. She was influential in securing the passage by the New York legislature, in 1860, of the act giving married women the possession of their earnings, and guardianship of their children. In 1868, with Mrs. E. C. Stanton and Parker Pillsbury, she began the publication of the 'Revolutionist,' a paper devoted to the emancipation of woman. In 1872 she cast ballots at the State and Congressional election in Rochester, N. Y., to test the application of the 14th and 15th Amendments of the United States Constitution. She was indicted for illegal voting and fined, but the fine was never exacted. Her last public appearance of note was as a delegate to the International Council of Women, in London, England, in 1899. In 1900 her birthday was celebrated by an affecting popular demonstration in Washington, D. C., and she retired from the presidency of the National American Woman Suffrage Association, which she had held for many years. See 'Life and Work of Susan B. Anthony' (1898).

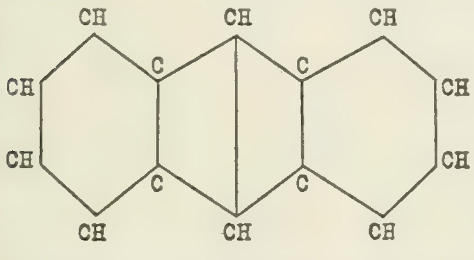
Anthony, ăn'tō-nĭ, **William Arnold,** an American physicist: b. in Coventry, R. I., 17 Nov. 1835. He was graduated from Yale Scientific School 1860, and taught science in various secondary schools 1860–67. He held chairs of physics and chemistry in Antioch College and Iowa Agricultural College 1869–72, was professor of physics at Cornell 1872–87, and consulting electrician, Manchester, Conn., 1887–93. Since the last-named year he has followed his profession in New York city and is professor of physics in Cooper Union School of Science. He has contributed many papers to the volumes of the scientific societies of which he is a member.

Anthosid'erite, ăn-thō-sĭd'ėr-īt (from the Greek *anthos*, "a flower," and *siderites*, "iron"), a mineral related to chloropal, occurring in fibrous tufts and sometimes in feathery forms resembling flowers. It is harder and heavier

than chloropal, is usually yellowish in color, and has the composition $2Fe_2O_3.9SiO_2.2H_2O$. It is found in Brazil.

An'thozo'a. See ACTINOZOA.

An'thracene (from *anthrax*, or *anthrac-*, "coal"), a hydrocarbon having the chemical formula $C_{14}H_{10}$, and the molecular structure



It is obtained by the distillation of coal-tar, occurring in that portion of the distillate which passes over at temperatures above 500° F. The "anthracene oil," as this part of the crude distillate is called, is allowed to stand in the cold for a week or so, until the greater part of the anthracene has crystallized out. The solidified portion when freed from the mother-liquor by pressure or by a centrifugal separator is ground up and washed with petroleum spirit to remove as much as practicable of the paraffin and other impurities. Anthracene so obtained is then sublimed and placed on the market as "50 per cent anthracene," although it may contain as much as 65 per cent of the pure substance. Its precise strength is best determined by treating a known weight with boiling glacial acetic acid and chromium trioxid, and observing the quantity of anthra-quinone that is formed. The crude anthracene of commerce may be further purified by distillation with caustic potash to which a little caustic lime has been added. Most of the impurities are removed in this way, and the product is further improved by subsequent washing with petroleum spirit, or with carbon disulphid, and finally by re-crystallization from a hot mixture of benzene and aniline. Pure anthracene crystallizes in white, monoclinic tablets melting at 415° F., and boiling at about 680°. It is insoluble in water and dissolves but slightly in other common solvents. It is soluble, however, in boiling glacial acetic acid, and also in hot benzene. It is used in large quantities for the manufacture of alizarin (q.v.). Anthracene is changed, by the action of sunlight, into an isomeric substance known as para-anthracene (or paranthracene), which melts at 472° F., and is reconverted into anthracene by fusion. See also COAL-TAR COLORS.

An'thracite, a variety of coal distinguished from other coals by its high proportion of carbon and small quantity of volatile matter. It has a conchoidal fracture, bright lustre, dense black color, and superior hardness. The percentage of carbon is variable, ranging from a minimum of about 80 per cent to a maximum of 95 per cent. Anthracite grades by imperceptible stages into bituminous coal, from which it has been produced by the action of heat or intense pressure. The coal-seams of eastern Pennsylvania are included in a series of strata which have been compressed and thrown into folds, while westward in the bituminous fields of Pennsylvania and Ohio the strata lie nearly horizontal. Beds of bituminous coal are frequently observed to grade into anthracite in the vicinity of igneous intrusions, as at Crested Butte, Colorado, and near Santa Fé, New Mexico. Where the heat has been very intense, however, the volatile matter is entirely driven off and graphite is formed.

Anthracite occurs in extensive deposits in many parts of the world. The most productive deposits are those of eastern Pennsylvania which occur in several detached fields, located as follows: The Northern field extending through the middle of Luzerne and Lackawanna counties; the Eastern Middle, between the Lehigh River and Catawissa Creek; the Western Middle, between the eastern headwaters of the Little Schuylkill River and the Susquehanna; and the Southern, or Pottsville field, extending from the Lehigh River at Mauch Chunk southwest to near the Susquehanna River. These fields comprise an area of something over 480 square miles and are classed under three general divisions, namely, Wyoming, Lehigh, and Schuylkill regions. The Bernice field in Sullivan County produces a semi-anthracite coal and is sometimes included with the anthracite fields. The strata with the beds of coal have been upturned and the outcropping edges subjected to long-continued erosion. The most important and persistent seam is the Mammoth, which in the Eastern Middle field has a thickness of from 60 to 90 feet and is over 100 feet thick in parts of the Southern and Western Middle fields. Altogether the workable seams number 15 or more, with a total thickness (increasing from west to east) ranging from 70 to 150 feet. The anthracite fields of Colorado and New Mexico are of much less importance. In foreign countries anthracite is mined in South Wales, Ireland, Belgium, France, Westphalia, and Russia, and it is known to occur in very large deposits in the province of Shan-Si, China. In the South Wales field only the northern portion yields anthracite, the rest of the output being semi-bituminous and bituminous coals.

Owing to its cleanliness and freedom from smoke anthracite is especially suited for household fuel; for steaming and metallurgical purposes it is inferior to bituminous coal. It ignites with difficulty and burns slowly with little flame, giving out intense heat. The amount of ash is small, ranging from 15 per cent to 6 or 7 per cent. The color of the ash is sometimes used as a basis of classification in trade, as in Pennsylvania anthracites, which are denominated white-ash and red-ash coals. But the color depends entirely upon the amount of iron present and is no criterion of the value. The following analyses show the relative proportions of fixed carbon, volatile matter, ash, etc., in various anthracites:

Fields	Fixed carbon	Volatile matter	Water	Sulphur	Ash
Eastern Middle, Pa....	86.38	3.08	4.12	1.62	5.92
Southern, Pa..........	83.81	4.27	3.09	0.64	8.18
Crested Butte, Colo..	82.33	9.96	0.81	0.81	6.96
South Wales..........	92.42	5.97	....	....	1.60

The preparation of anthracite for the market consists in freeing it from slate and dust and

sorting it into suitable sizes. Owing to the practical absence of volatile matter, anthracite will not burn unless the lumps are of fairly uniform size. When hoisted from the mine it is first passed over a screen which allows most of the fine coal to pass through. The lump coal is then sorted for the purpose of removing the shale and slate, and the pure material is crushed between rolls and screened into the market sizes. In the United States the sizes generally recognized are the following: Broken or grate, which passes through a screen of 4-inch mesh but not through 2.5-inch mesh; egg, 2.5-inch-1.75 inch: stove, 1.75 inch-1.25 inch; chestnut, 1.25-inch-0.75-inch: pea, 0.75-inch-0.50-inch; and buckwheat, 0.50-inch-0.25-inch. Larger sizes than the above are known as lump and steamboat, and smaller sizes as rice, mustard-seed, etc. The sizes from broken to chestnut inclusive are known as the domestic prepared sizes and constitute at present about 60 per cent of the output. The waste or fine coal which commonly amounts to as much as 10 per cent of the material mined is known as culm. Immense heaps of this fine coal have accumulated at the mines, but with the improved processes of screening and separation much of it is now saved and sold to manufacturing plants.

The growth of the anthracite mining industry in the United States has been very rapid. There are records showing that Pennsylvania anthracite was used for fuel as early as 1768, but mining was not carried on to any extent until about 1820. The growth of the industry from this time to the close of the century is shown in the following table:

	Long tons		Long tons
1820	365	1870	16,182,191
1830	174,734	1880	23,437,242
1840	864,379	1890	36,615,459
1850	3,358,899	1900	45,107,484
1860	8,513,123		

The production and value of Pennsylvania anthracite and the number of employees engaged in the industry during the period 1897-1901 were as follows:

	Production long tons	Value	Number of Employees
1897	46,974,715	79,301,954	149,557
1898	47,663,076	75,414,537	145,184
1899	53,944,647	88,142,130	139,608
1900	51,221,353	85,757,851	144,206
1901	60,242,560	112,504,020	145,309

Almost the entire output of anthracite is consumed as domestic fuel. A small portion is used for manufacturing purposes in large cities, but it is being gradually superseded for this purpose by the cheaper bituminous coal. See COAL.

Anthrac'nose, a group of fungous diseases caused by various species of *Glœosporium* and *Colletotrichum,* which appear upon the green parts of plants as roundish spots with more or less sunken light centres and darker margins. They often cause serious damage to cultivated crops, especially grape, strawberry, raspberry, spinach, egg-plant, cotton, and cucumber, under which titles they will be more fully discussed. For methods of control see FUNGICIDE.

An'thracother'ium, an extinct pig-like animal, inhabiting Europe and North America during the Oligocene and Miocene epochs. The teeth are intermediate between those of pigs and ruminants, but it is not in the direct line of descent of either, forming a side branch which left no descendants. The name, given by Cuvier in 1822, means "beast of the coal" (*ἄνθραξ* coal, *θηρίον* beast), and is derived from the fact that its remains were first discovered in the Tertiary lignite beds of France.

Anthraquinon'e, ăn'thra-quĭn-ōn' (from *anthra-cene* + *quinone*), a substance derived from anthracene by the action of oxidizing agents, and used in the preparation of alizarin. It may be conveniently prepared on a small scale by dissolving anthracene in glacial acetic acid, adding potassium bichromate, and heating to 212° F. The acetic acid is then distilled off, and the anthraquinone precipitated by water. On the large scale sulphuric acid is used in the place of the acetic acid. Anthracene has the formula $C_{14}H_8O_2$, and is insoluble (or nearly so) in water and alcohol, and but slightly soluble in benzene. It dissolves in hot sulphuric acid, separating out again, without change, upon cooling.

Anthrax, the name of a disease occurring epidemically among herbivora, chiefly oxen and sheep, and occasionally affecting man. It is also called malignant pustule, splenic fever, wool-sorters' disease, charbon, milzbrand. It is caused by a rod-shaped bacterium, the *Bacillus anthracis,* first seen in 1849 and isolated in 1863, and conclusively proved by Koch in 1876 to be the cause of the disease, this being one of the first diseases demonstrated to be caused by bacteria.

In man the bacillus is usually acquired by handling the hide of an animal having died from the disease. A local lesion, the malignant pustule, is formed, and this may lead to wide-spread infection with œdema and lymphatic invasion, attended by fever, gastro-enteritis, collapse, and death. The infection may remain localized, however, and the patient may recover. Less often the infection takes place in the respiratory tract, the patient having breathed the bacillus in the dust arising from handling hides or sorting wool; in such cases a rapidly fatal form of hemorrhagic œdema may develop. A still rarer form of the disease in man affects the intestinal tract. The bacillus of anthrax is one of the largest of the pathogenic bacteria. It is 6-8 microns $\left\{\frac{6\text{-}8}{25{,}000}\right\}$ inches long and 1.5 microns thick, being a short rod with square edges, and growing in chains. The protoplasm is finely granular and it forms spores about the centre of the bacillus. It grows very rapidly on all of the commonly used bacteriological culture media, best at a temperature of 35° C., but its multiplication ceases at temperatures below 12° C. or above 45° C. The bacilli are readily killed by temperatures of 60° C., but the spores are very resistant, and dry heat at 140° C. must be applied for several hours to kill them. In a dry condition they remain viable for several years and will resist boiling water for at least five minutes. The gastric juice

also does not destroy them readily. The bacteria are found in the blood and throughout the organs of animals dying of anthrax. They are particularly numerous in the spleen and in the lymphatic structures. They poison the body by the development of a toxin or toxins which in turn cause degeneration of the tissues of the body.

Anthrax is one of the diseases in which a serum therapy was instituted early. Thus far it has not proved of signal service, although a protective serum has been made by which animals may be immunized against the disease.

Anthrax in animals is a comparatively common disease, affecting sheep, cattle, and, more rarely, horses and members of the deer family. It is rare among the carnivora. The disease is not geographically confined, and animals in various parts of the world are affected by it. It is naturally less common in countries in which there is some legislative control, and rarer at present than in former times. In Britain the mortality is small; in France, at one time, as many as 10 per cent of the sheep died annually of anthrax. Since the modern method of immunizing cattle has been introduced the mortality has been much lessened. The symptoms vary widely, but at least three marked groups are observable. In some instances the affected animal develops symptoms of extreme collapse; it drops to the ground; the pulse and respiration are quickened, there is difficulty in breathing, and the animal dies in convulsions within a comparatively short time. A commoner type of attack is begun by symptoms of general distress, the animal is "off its feed," the pulse and respiration are quickened, chills develop, the temperature rises to 103 or 104° F., bloody diarrhœa occurs, bloody nasal catarrh. There then may develop convulsive movements; there is rapid loss of strength, and the animal may die in from 10 to 48 hours, sometimes at the end of 3 to 4 days. A third type is characterized by a slow onset, the lymphatic structures are involved, they swell and form carbuncles, which may ulcerate. General symptoms of infection may develop — the spleen may enlarge, bloody discharges are common, and the animal dies of generalized hemorrhagic œdema. The diagnosis is readily made in all cases by a microscopical examination of the blood. Different animals show marked variations in susceptibility. The sheep, save Algerian, ox, guinea-pig, and mouse, are all very susceptible, but the goat, horse, deer, and pig are less often attacked. Man may be placed next in the order of liability; the white rat, adult carnivora, birds, and amphibia are immune. The disease is conveyed to animals largely by way of the intestinal canal. The bacilli are ubiquitous in the grass and hay about an infected area.

Preventive inoculation.—Pasteur first evolved a method of inoculation by an attenuated virus, a sort of hardening the animal, as it were, that subsequently made it resistant to the virile bacteria. Although other methods, notably the use of anti-anthrax serum, have been used, the attenuated virus method seems to give the best results. Surgical methods are the only mode of treatment for man.

An'threnus. See CARPET BEETLE.

An'thropoid Apes, a term applied to those apes (family *Simiidæ*) nearest in their organization to man. See APE.

An'thropol'atry, the worship of man, a term always employed in reproach. It was applied by the Apollinarians to the orthodox Christians of the 4th and 5th centuries, who in their devotion to Christ worshipped, as was declared, only a man in whom God dwelt.

An'thropol'ogy (from Greek *anthrōpos,* man, and *logos,* doctrine), the science or branch of knowledge dealing with mankind in its most general aspects and characteristics, and as forming an organic whole. It derives its materials from the most varied sources, and rests upon other sciences, among which may be mentioned physiology, psychology, ethnology, archæology, ethics, and the study of religion, the rise of arts and science, and the history of civilization. Anthropology takes account of the totality of the moral and physical characteristics of man and of the different races of man; deals with the ethnological relationship existing between the races of former times and those now living, treats of man's place in nature, the relation in which he stands to the animals whose structure most nearly approaches his own, and the theory of evolution and development from lower to higher forms as applied to man. Anthropology considers also the how, when, and where of man's first appearance on the earth, the condition in which he originally existed, and the influences, means, and methods which have given rise to existing civilization. (See ARCHÆOLOGY; CIVILIZATION; ETHNOLOGY; MAN.) Consult: Tyler, 'Introduction to the Study of Man and Civilization' (1881), and see also the bibliography appended to the next article.

Anthropology, American. Although anthropology, or the science of man, is sometimes classed among the older branches of knowledge, it is, in its modern aspects, the youngest of all. Its relations to the older sciences are seen clearly when the object-matter or the special phenomena treated in the several sciences are compared. The special phenomena considered in the simplest of the sciences are cosmic bodies controlled by gravity,— that is, by a wholly external force. The phenomena treated in the second of the objective sciences in order of development are elementary, and their substances controlled especially by affinity, though incidentally by gravity,— that is, in part by what may be considered intrinsic forces, though chiefly by extrinsic factors. The phenomena dealt with in the next science in order of development (and also in complexity) are plants, of which the essential property is vitality, which is superadded to affinity and gravity; and the phenomena are controlled in considerable measure by intrinsic forces maturing in heredity. The object-matter of the next science, or group of sciences, is animals, whose special property is motility — a property coexisting with the vitality, affinity, and gravity of the simpler

sciences; and among the self-motile organisms the controlling forces are largely intrinsic. In the remaining class of natural phenomena, or mankind, the special property is that of mentality, superadded in turn to the special attributes of the simpler classes; and through the possession of this property mankind rise largely above environment and pass under the control of essentially intrinsic forces, merely adjusted to such external forces as those of gravity, affinity, etc. Viewed thus with respect to primary-object matter, the sciences are seen to fall into a natural series expressing at once the order of historical development and the degree of complexity. The series is of interest not merely as showing the place of anthropology among the sciences, but as indicating the breadth of the foundation on which the science of man is built; it may be deemed the offspring of all the older sciences, and borrows methods and principles from all; yet it occupies an essentially distinct field, defined by a special attribute existing only in organized bodies and playing the leading role only in the single sapient species of a unique genus — *Homo sapiens*.

While anthropology treats of a single class of phenomena, these are of such variety and complexity that the field of the science is broad — indeed, the general science may properly be regarded as made up of a number of special sciences of which several were cultivated long before the full extent of the human science was appreciated. The order of development of these special sciences is of much interest, and well illustrates (as does the history of science in general) the passage of definite science from the abnormal to the normal and from the remote to the near. Probably the first of the anthropologic sciences which came up in prehistoric times was pathology: certainly the least developed savages known to students are cognizant of pathologic conditions and possess systems of action and thought connected with those conditions. Probably, too, the second germ of definite knowledge related to physiology; for primitive folk usually display some notion of the normal reverse of pathologic conditions, and impute physiologic properties to animate and other bodies even before the organs are clearly defined. It is probable also that a mystical etiology followed, leading to a thaumaturgic or sortilegic practice which may be called primitive medicine and surgery; certainly during prehistoric times such major operations as trepanning were performed in many widely separated regions, with greater frequency than in modern hospital practice, and with fair if not excellent success, despite the fact that the diagnosis was wholly irrational and the apparatus and processes astonishingly crude. Within the historical period these primitive systems were gradually rendered definite and rational chiefly through the practice of the healing art; and as the spirit of exploration and discovery advanced, thought was stimulated by observations on other races; yet it was not until after Linné, Cuvier, and others laid the foundations for botany (or phytology) and zoology that the science of man began to take definite form. In the centuries from Linné to Darwin and Huxley man was regarded either as entirely outside the domain of scientific research or else as an animal genus merely; and during this period most students were content to investigate the purely physical (and individual) characters of the genus. Through the researches of the times anthropology was raised to a place among the recognized sciences, and various special methods were introduced, notably, anthropometry (including craniometry); the science of the time being that which is now commonly called physical anthropology, or somatology. Concurrently with the objective investigations, studies of the mental attributes of mankind were carried forward, and a fairly definite system of introspective psychology grew up. The development of physical anthropology and introspective psychology may be deemed the gift of Europe and of 17 centuries to the science of man. With the extension of colonization in America, the pioneers were brought into contact with alien tribes; these were objects first of curiosity and afterward of careful study with a view to the maintenance of amicable relations. The great lesson of the contact was the discovery that the actions and thoughts (or the conduct) of the alien folk were of immeasurably greater consequence than their physical characters. It was soon perceived that the key to primitive thought is the language by which it is expressed; and John Eliot, in Massachusetts, with scores of other students and missionaries, mastered the languages of the tribesmen with the view of promoting harmony and friendship. The early work was that of philanthropists and statesmen rather than scientists; but Gallatin went so far beyond his predecessors as to classify the American aborigines on the basis of language, thereby laying the foundation for a new anthropology, or a science of human activities. Morgan extended the study to the social organization of the tribes, and Brinton to their mythologic or religious systems; while, still later, Powell brought the earlier studies together and developed the science of human activities, which he called demology, or demonomy. It is to be noted that the unit of demology is not the individual, as in physical anthropology or somatology, but the group — the pair, family, clan, tribe, city, or nation. This science itself covers so broad a field that subdivision has been found convenient. Accordingly recent workers recognize a science of arts, or æsthetology, treating of the characters and the natural history (or development) of æsthetic symbols and devices; a science of industries, or technology, which treats similarly of implements, tools, machines, and other industrial instrumentalities; a science of laws, or sociology, dealing with the characters and development of social organization and institutions; a science of languages, or philology, devoted to the study of human speech and writing; and a science of philosophies, including myths, opinions, beliefs, and attendant customs and observances, which is conveniently called sophiology. With the progress of research and the definition of the special sciences it became clear to American students that while the human characters may conveniently be interpreted in terms of physical activities, they may be still more conveniently and simply expressed in terms of psychic or mental activities. Following this mode of interpretation it has been found feasible to classify mankind in four great

groups, each representing a fairly well-defined stage in intellectual, social, and moral development. The first of these stages is that commonly called savagery, in which law is based on kinship traced in the female line, and in which language and belief, as well as the arts and industries, are more or less inchoate. The second is that of barbarism, or patriarchy, in which the law rests on kinship traced in the paternal line, and in which arts, industries, languages, and faiths attain distinctive development. The third (sometimes connected with the second through feudal systems) is that of civilization, or the phase of civilization characterized by monarchical government, in which the law rests on recognition of property right, especially in land; this stage is characterized by writing, conventional art, differentiated industries, and especially by the Christian religion. The fourth stage is that properly called enlightenment, in which the law rests on recognition of human rights to life, liberty, and the pursuit of happiness, and in which arts are perfected, industries multiplied, languages blent and simplified, and faiths refined and ennobled. The recognition of these stages reacted on the primary motive of modern anthropology, and led to a clearer view of the significance of mentality not only in human affairs but in the economy of the universe. Accordingly anthropology may be said to have contributed to human knowledge one of the five cardinal principles of science. The first of these, contributed chiefly by chemistry, is the indestructibility of matter; the second, established by the aid of several sciences, is the conservation of energy or the persistence of motion; the third, derived largely from biology, is the development of species; the fourth, obtained by comparison of several sciences, is the uniformity of Nature; while the fifth, contributed by modern anthropology (although forecast by Bacon in his *Novum Organum*) is the responsivity of mind. The applications of these principles, especially that last named, are innumerable and highly useful; in large measure they give shape to the anthropologic researches of recent times.

Various instrumentalities for anthropologic research have grown up in America, especially during the last quarter of the 19th century. Perhaps the most efficient of these is the Bureau of American Ethnology, established in 1879 through the efforts of J. W. Powell; its work has been directed wholly to the aborigines, yet the researches have been so shaped as to bring out the essential principles of demology, or the science of mankind considered in a collective aspect. Important investigations have been conducted also in various museums, notably, the American Museum of Natural History in New York, whose work has been greatly enhanced through the Jesup North Pacific expeditions, organized as a part of the Museum establishment. The Peabody Museum connected with Harvard University, the Field Columbian Museum of Chicago, the Free Museum attached to the University of Pennsylvania, the Golden Gate Park Museum of San Francisco, and the Carnegie Museum of Pittsburg, have also made rich contributions to the science of anthropology in America, while the United States National Museum has been a centre of richly productive activity. Various volunteer organizations have served to guide and co-ordinate the work of individual investigators. One of the most influential of these has been the Anthropological Society of Washington, a pioneer in systemizing anthropology. It is organized in sections corresponding to the principal divisions of the science, namely: A, somatology; B, psychology; C, æsthetology; D, technology; E, sociology; F, philology; G, sophiology. Another efficient organization is the American Ethnological Society, with headquarters in New York; while the section of anthropology of the American Association for the Advancement of Science until recently afforded the sole opportunity for national gatherings of anthropologists. The Archæological Institute of America and the American Folk-Lore Society may be said to occupy portions of the field; and a number of other societies and sections have encouraged research. In the summer of 1902 a national organization of anthropologists was created, under the title American Anthropological Association; its membership includes the leading anthropologists of America. Several universities and colleges support anthropology either through established chairs or otherwise; Columbia, California, Chicago, and Harvard offer excellent facilities for both instruction and research in anthropology.

As customarily defined in American writing, anthropology includes ethnology and archæology, but does not embrace the closely cognate science of psychology. This science has been successfully cultivated in America during recent years; departments of experimental psychology are maintained in several universities, two or three excellent journals are conducted, and the experimental science is co-ordinated with the older, or introspective, psychology so effectively that America must be placed in the foremost rank, if not in the lead, of the countries in which the science is undergoing development. The special instrumentalities and results are indicated elsewhere.

Ethnology, or the science of races, ranks among the more important aspects of anthropology. Until the last quarter of the 19th century it was customary to define the races of mankind on the basis of color, character of hair, form of head, stature, color and attitude of eyes, and various other physical characters; and most of the applications of anthropometry and craniometry were made in connection with the description of races (ethnography) or in the systematic classification and discussion to which the term ethnology is properly applied. The ethnic characters recognized by various students are numerous and diverse; many are of local or special value only; and the definitions of races have been nearly as numerous as the writers on ethnologic subjects. The number of human races recognized by different authors varies from four or five to several score; but the modern tendency is to recognize only four or five leading types as ethnic varieties, or distinct races of mankind, namely, (1) the Caucasian or white race, (2) the Mongolian or yellow race, (3) the Malayan or brown race, (4) the American or red race, and (5) the African or black race. The principal American contributions to the subject of ethnology have been made since 1875, when Powell began the classification of the aboriginal tribes on the demotic

basis,—that is, on the basis of the human activities. As the studies progressed it was found that the native tribes (and other primitive peoples as well) might be classified on the basis of æsthetic or industrial character, on the basis of belief, or mythology, and still more satisfactorily on the basis of social organization, or law; but that the most convenient classification was that on the basis of language. Accordingly Gallatin's classification was revived and extended to the aborigines of North America (chiefly north of Mexico); and the thousand or more tribes known through current research and early record were grouped in some 60 linguistic stocks. These are as follows, in alphabetic but not geographical order:

	Tribes		Tribes
Algonquian	36	Natchesan	2
Athapascan	53	Palaihnihan	3
Attacapan	2	Piman	7
Beothukan	1	Pujunan	26
Caddoan	9	Quoratean	3
Chimakuan	2	Salinan	2
Chimarikan	2	Salishan	64
Chimmesyan	8	Sastean	1
Chinookan	11	Serian	3
Chitimachan	1	Shahaptian	7
Chumashan	6	Shoshonean	12
Coahuiltecan	22	Siouan	68
Copehan	22	Skittagetan	17
Costanoan	5	Takilman	1
Eskimauan	70	Tanoan	14
Esselenian	1	Timuquanan	60
Iroquoian	13	Tonikan	3
Kalapooian	8	Tonkawan	1
Karankawan	1	Uchean	1
Keresan	17	Waiilatpuan	2
Kiowan	1	Wakashan	37
Kitunahan	4	Washoan	1
Koluschan	12	Weitspekan	6
Kulanapan	30	Wishoskan	3
Kusan	4	Yakoan	4
Latuamian	4	Yanan	1
Mariposan	24	Yukian	5
Moquelumnan	35	Yuman	9
Muskhogean	9	Zuñian	1
Nahuatlan	?		

In connection with the classification of the tribes much information has been gained as to the migrations and other movements of the aborigines. As indicated by the linguistic diversity, the red race is by no means to be considered a unit; it comprises, on the contrary, an assemblage of distinct or slightly related peoples, whose movements must have been largely independent during many centuries of prehistoric time. There was, indeed, a strong tendency toward the absorption of weaker tribes by stronger, and toward the enlargement of groups by confederation; the most important confederacies of North America being the Iroquoian confederacy or "Six Nations," the Dakota or Sioux confederacy or "Seven Peoples," the Muskhogean confederacy of the eastern Gulf slope, and the indefinitely known Nahuatlan or Aztec confederacy of Mexico. The courses of migration of typical groups have been traced. The best known example is that of the Siouan Indians, who apparently pushed up the Atlantic coast, perhaps under pressure from a southern competitor, to Chesapeake Bay, by which they were diverted inland; reaching the habitat of the buffalo, which crossed the Appalachian Mountains in the neighborhood of the Potomac River, they followed this easy food source westward, across the mountains, down the Ohio to the Mississippi, and thence in northern and southern columns (the "up-stream" and the "down-stream" people) far out on the great plains, where most of the Siouan tribes were found by Caucasian explorers. There are clear indications that many of the Algonquian tribes also pushed inland from the northern Atlantic coast, spreading over the Lake region largely through the effective aid of the birch-bark canoe; and there are similar indications that the Athapascan tribes of the northern portion of the continent likewise pushed from the coast toward the interior and southward into the Pueblo region by means of the same simple transportation device; while the Eskimo clung to the coasts, pushing east to northern Greenland and west to and across Bering Strait into northeastern Asia. The intertribal relations farther south on the Pacific coast were such as to force maritime peoples into the arid interior, along the cañons and upon the plateaus — where some of the Pueblo tribes, like the desert peoples of the Gila Valley, still retain clear vestiges of a cult of the sea. On the whole, the traces of tribal migrations clearly indicate a tendency to move inland from the coasts and substitute agricultural habits for the simpler customs of fishery and chase. Naturally all inquiries bear on the question of the peopling of America; but it is significant that the careful researches of a quarter-century have added practically no evidence of the peopling of the New World from the Old — the only known aboriginal crossing of Bering Strait being that by the Eskimo migrating west. The records of the Jesup expedition tend to indicate that traditions were carried from America to Asia during prehistoric times, but not in the other direction; while certain studies of cultivated plants suggest a westerly migration from South America to Polynesia, and no trustworthy indication of aboriginal immigration has been found. A few ethnologists incline to the opinion that mankind developed in America earlier than in Asia, and passed westward perhaps during the Pliocene or the early Pleistocene; but the dearth of human relics of geologic antiquity tends against this opinion. Some of the most competent students favor the view that howsoever the human prototype may have been introduced in America, the tribes originated independently before speech was developed, and that since this early time the lines of development have converged; so that the prescriptorial history of America may be likened to the written history of Europe, in which tribes, peoples, languages, and customs have progressively blent and united throughout the last two millenniums. On the whole it must be said that ethnologic researches have thus far failed to answer many of the mooted questions concerning the origin and early movements of the American aborigines; yet it is not to be forgotten that they have resulted in the fullest and most faithful descriptions of primitive men ever given to the world.

The ethnologic inquiries in America have constantly stimulated archæologic research — indeed, the special merit of American archæology grows out of the fact that the American interpretations of relics are based on actual observation of primitive peoples rather than on inferences peculiar to an entirely distinct culture stage. In general, archæology, as the term is employed in this country, may be defined as a special aspect of anthropology; more strictly, it

represents the archaic or prehistoric division of technology and æsthetology. In many respects America has been found to afford a peculiarly instructive field for the archæologist: relics of the Stone Age abound in unequaled profusion; the great mounds and earthworks of the Mississippi Valley are practically unique; the cemeteries, filled with fictile ware in North America, and the rich huacas of the Andes, are without parallel elsewhere; the ruined cities of Yucatan, Mexico, and Peru have awakened the interest of the world; and all of these monuments of the past may be, and most of them have been, studied in the light of surviving customs of the descendants of their makers. The investigation of relics pertaining to the arts has supplemented the studies among living tribes, and has shown that æsthetic concepts arise in symbolism and pass through a crude conventionalism before they mature in faithful representations; and in like manner the prehistoric industrial devices fall into a series coinciding with that found among living tribes, which passes from the symbolic first to the conventional and only long afterward to the simply useful. Thus, the earliest weapons were teeth, claws, beaks, or shells of animal tutelaries; in the next stage they were imitations of the natural weapons; the devices next underwent slow modification, determined by the character of the material; and in a relatively advanced stage of thought the germ of invention was introduced. The tracing of the development of industrial devices of primitive men is one of America's chief contributions to the science of archæology; and it is especially significant by reason of its conformity with the course of social development established through ethnologic researches. The sequence is a direct record of growing mentality; and it runs from the stage in which men thought as beasts up to that in which some of the aboriginal tribesmen were able to meet Caucasian invaders on terms of approximately equal psychic development. The record indicates that perhaps the longest step in industrial development was that leading to the use of the edged implement of stone or other material; and that next to this the hardest step was that leading to the smelting of metals, which some of the aborigines had just approached at the time of the Columbian discovery. The principal stages in industrial development, attested alike by the prehistoric relics of America and the customs of the lowest living tribes, are as follows:

Some of the more interesting archæologic investigations of the western hemisphere relate to the antiquity of man. From time to time discoveries of human relics in deposits of geologic antiquity are reported, and it has become customary for archæologists and geologists to visit the localities and investigate the associations critically. In most cases the examinations have led to the rejection of the evidence on one ground or another, so that very few cases can be regarded as indicating extreme human antiquity in the western hemisphere. There is, indeed, a strong presumption that man has lived in the western world many thousands of years; almost certainly he was there before the last ice invasion, possibly before the first advent of Pleistocene ice; for otherwise it would be difficult to account for the differentiation of the Eskimauan from the Athapascan and other peoples, to explain the development of complex social organization by the slow processes of primitive life, or to understand various other lines of development — yet the tangible evidence remains meagre. Probably the most trustworthy indication is that afforded by an apparently wrought human femur, reported by Putnam, from the glacial gravel at Trenton.

The finding of a human skull at a considerable depth in apparently undisturbed deposits near Lansing, Kansas, has attracted much attention, but the modern aspect of the cranium and the uncertainty as to the age of the deposits greatly weaken its testimony. On the whole, the conservative American archæologist is compelled to rest the case for the higher antiquity of man on the western hemisphere rather on a strong presumption than on decisive evidence of relics in deposits of known geological age. See ARCHÆOLOGY (*American*); INDIANS; MOUND BUILDERS.

An'thropom'etry (from the Greek *anthrōpos*, man, and *metron*, measure), a term denoting the science having for its object the systematic examination of the height, weight, and other physical characteristics of the human body. In 1875 the British Association appointed a committee to collect observations in con-

STAGES IN INDUSTRIAL DEVELOPMENT.

STAGES	TYPICAL MATERIALS	TYPICAL PRODUCTS	ESSENTIAL IDEAS
1. Zoomimic	Bestial organs	Awls, spears, harpoons, arrows	Zootheistic faith
A. Transitional	Symbolized organs	Piercing and tearing implements	Faith + craft
2. Protolithic	Natural stones	Hammers and grinders—hupfs and ahsts	Mechanical chance
B. Transitional	Cleft stones	Grinders and cutters	Chance + craft
3. Technolithic	Artificialized stones	Chipped, battered and polished implements	Designed shapement by molar action
C. Transitional	Malleable native metals	Copper celts, gold ornaments, etc.	Designed shapement by molar action + chance heating
4. Metallurgic	Smelted ores	Steel tools, etc.	Shapement by molar and molecular action

nection with this department, and in 1883 they submitted to the association their final report, from which is derived the following information. The variations in stature, weight, and complexion existing in different districts of the British isles appear to be chiefly due to differences of racial origin, and this influence predominates over all others. We have reason to believe, from historical and antiquarian researches, that the ancient Caledonii, the Belgæ, and Cimbri, and the Saxons and Frisians, as well as the Danes and Normans, were all people of great stature. On the other hand, the prehistoric (neolithic) race or races of Great Britain appear to have been of low or moderate stature. Accordingly the higher statures are found in the Pictish and Cimbro-British districts of Galloway; in the Anglo-Danish districts of North and East Yorkshire, Westmoreland, and Lincolnshire, and in Cumberland, whose people are ethnologically intermediate between the two. Lothian and Berwickshire are mainly Anglian, while the Perthshire Highlanders are the most clearly identified as the descendants of the Caledonii. Norfolk holds a high position in regard to stature, owing to a large admixture of Danish blood on the coast. There is a fringe of moderately high stature all round the coast from Norfolk to Cornwall, while the inland people, retaining more of the ancient British blood, yield lower averages. Middlesex and Hertfordshire, which stand very low, were later and less perfectly colonized by the Anglo-Saxons than the surrounding counties, and nearly the same may be said of the counties surrounding the Severn estuary and the Welsh border. Cornwall stands higher than the surrounding counties, and this is probably due to its having become the refuge of the military class of south Britain, in the main of Belgic origin. Flint and Denbigh owe their superiority to the other Welsh counties to the immigration of the Cumbrian and Strathclyde Britons. The inhabitants of the western provinces of Ireland possess a high stature similar to that found in the Scotch Highlands, with which they may have a common racial origin, while the lower stature of the eastern provinces is probably traceable to the comparatively recent Scotch and English immigrations. As to geographical distribution, the inhabitants of the more elevated districts possess a greater stature than those of alluvial plains. The counties forming the river valleys of the Severn and Wye, the Thames, the Dee, and Mersey, the Clyde, the Trent, and the fen district of Cambridge and Huntingdon, show a lower stature than the surrounding counties inhabited by persons of a similar racial origin. With respect to latitude and climate, the inhabitants of the northern and colder districts possess greater stature than those of the southern and warmer parts of the island; those of the northeastern and drier regions are taller than those of the southwestern and damper climates. A similar disposition of stature has been found to exist in France and Italy, the inhabitants of both these countries being taller in the northern than in the southern provinces. The same rule applies to the whole of the countries of Europe with respect to each other. Grouping the observations according to the place of birth in England, Wales, Scotland, and Ireland the general results may be summarized as follows: The Scotch male adults stand first in height (68.71 inches), the Irish second (67.90 inches), the English third (67.68 inches), and the Welsh last (66.66 inches). In weight the Scotch take the first place (165.3 pounds), the Welsh the second (158.3 pounds), the English the third (155.0 pounds), and the Irish the last (154.1 pounds). For each inch of stature a Scotchman weighs 2.406 pounds, a Welshman 2.375 pounds, an Englishman 2.301 pounds, and an Irishman 2.270 pounds. The chest-girth of the adult British male (the measurements being, however, mainly those of Englishmen) varies from 45 to 27 inches, the mean being 36 inches. The strength of the arms exerted as in drawing a bow ranges from 150 to 30 pounds, the mean being 70 pounds. The average height of adult females in England is 62.65 inches, being 4.71 inches less than the male average; the average weight of females is 122.8 pounds, being 32.2 pounds under that of the males. The females are stated to average little more than half the strength of males measured by straining the arms, but the observations were obtained from pupils in training schools for mistresses, and from shop assistants, so that the average is no doubt much lower than if the laboring classes had been included. The average height of the adult males of the principal races or nationalities of the world may be given as under; but more numerous measurements might alter some of the figures considerably: Polynesians, 69.33 inches; Patagonians, 69 inches; Negroes of the Congo, 69 inches; Scotch 68.71 inches; Iroquois Indians, 68.28 inches; Irish, 67.90 inches; United States (whites) 67.67 inches; English, 67.68 inches; Norwegians, 67.66 inches; Zulus, 67.19 inches; Welsh, 66.66 inches; Danes, 66.65 inches; Dutch, 66.62 inches; American negroes, 66.62 inches; Hungarians, 66.58 inches; Germans, 66.54 inches; Swiss, 66.43 inches; Belgians, 66.38 inches; French, 66.23 inches; Berbers, 66.10 inches; Arabs, 66.08 inches; Russians, 66.04 inches; Italians, 66 inches; Spaniards, 65.66 inches; Esquimaux, 65.10 inches; Papuans, 64.78 inches; Hindus, 64.76 inches; Chinese, 64.17 inches; Poles, 63.87 inches; Finns, 63.60 inches; Japanese, 63.11 inches; Peruvians, 63 inches; Malays, 62.34 inches; Lapps, 59.2 inches; Bosjesmans, 52.78 inches. The average stature of man is thus about 65.25 inches. With respect to the measurement of children at birth it is found that the average length of a British male infant is 19.52 inches, and of females 19.32 inches. The average naked weight of male infants is 7.12 pounds, of females 6.94 pounds. Growth is most rapid during the first five years of life, and during that period the rate of increase is about the same in both sexes, the gain being 21.51 inches. From 5 to 10 years boys grow a little more rapidly than girls, the male increase being 10.81 inches, the female 10.50 inches. From 10 to 15 years girls grow more rapidly than boys, and at the ages of 11½ to 14½ are actually taller, and from 12½ to 15½ actually heavier than boys. From 15 to 20 years boys again take the lead, and grow at first rapidly, then gradually slower, and complete their growth at about 23 years. After 15 girls grow very slowly, and attain their full stature about the 20th year. The strength of males increases rapidly from 12 to 19 years and at a rate simi-

ear to the weight; more slowly and regularly up to 30 years, after which it declines at an increasing rate to the age of 60. The strength of females increases at a more uniform rate from 9 to 19 years, more slowly to 30, after which it decreases in a manner similar to that of males.

An'thropomor'phism, a term expressing the representation or conception of Deity under a human form, or with human attributes and affections. Such a conception springs from the natural inaptitude of the human mind for conceiving spiritual things except through sensuous images, and in its consequent tendency to accept such expressions as those of Scripture when it speaks of the eye, the ear, and the hand of God, of his seeing and hearing, of his remembering and forgetting, of his making man in his own image, etc., in a too literal sense. The term is also applied to that doctrine which attributes to animals mental faculties of the same nature as those of man, though much lower in degree: strictly called biological anthropomorphism, to distinguish it from anthropomorphism proper, or theological anthropomorphism.

An'thropoph'agi, the name given to individuals or tribes by whom human flesh is eaten: man-eaters, cannibals. The Caribs are said to have been cannibals at the time of the Spanish conquest of America, and the word "cannibal" is derived from their name.

An'ti, or CAMPA, a warlike tribe of southern Peru on the eastern slope of the Andes. Their principal garment is a poncho belted at the waist. The men are workers in metal to a considerable extent, and the women are skilful weavers. They cultivate the ground, wild animals, tamed, serving as beasts of burden.

An'tia'rin, the poisonous principle found in the milky juice of the upas tree (*Antiaris toxicaria*) in Java. It has the probable formula $C_{14}H_{20}O_6 + 2H_2O$. The gum prepared from the upas juice is used by the natives of Java for poisoning arrows. Antiarin, when taken into the stomach or introduced into the circulation through a wound, causes great prostration, and, in sufficient quantity, paralysis of the heart.

Antibes, äṅ-tēb, a fortified town and seaport of France, on the Mediterranean, 11 miles south-southwest of Nice; founded about 340 B.C. by a colony of Greeks, who named it Antipolis. It has a naval school, and exports olives, anchovies, perfumery, etc. Pop. (1901), town, 5,512; commune, 10,947.

An'tibo'dy. See IMMUNITY.

Anti-Catholic Riots. See ORANGEMEN.

An'tichlor, ăn'tĭ-klōr (from *chlorine* and *anti*). In bleaching, any substance used to eliminate, by chemical means, the last traces of chlorine from a material that has been bleached by the action of a chlorine compound. The free chlorine can be largely removed by mere washing, but it cannot be entirely eliminated in this manner, and the residuum, if not removed by chemical means, is injurious to the material and causes it to disintegrate slowly. Sulphur dioxid was long used as an antichlor, its action being indicated by the following formula: $SO_2 + 2H_2O + 2Cl = H_2SO_4 + 2HCl$; that is, it combines with the chlorine to form sulphuric and hydrochloric acids. Sulphite of soda, Na_2SO_3, is equally effective, its action being as follows: $Na_2SO_3 + H_2O + 2Cl = Na_2SO_4 + 2HCl$. Sodium thiosulphate (better known in the arts as hyposulphite of soda, or "hypo,") is now more commonly used as an antichlor, since it is both cheaper and more efficacious. Its formula is $Na_2S_2O_3$, and its action is as follows: $Na_2S_2O_3 + 5H_2O + 8Cl = Na_2SO_4 + 8HCl + H_2SO_4$. (Sodium thiosulphate, water, and chlorine yield sodium sulphate, hydrochloric acid, and sulphuric acid.) In practice carbonate of soda is often added to the antichlor to neutralize the acids formed by the absorption of the chlorine. The resulting salts of soda are easily washed out of the material treated; and no damage results even if they are not entirely removed.

An'tichrist, a term of Biblical origin, but occurring only in the Epistles of John, where it signifies a person or persons who deny the Father and the Son and disown the incarnation and messiahship of Jesus. They are deceivers whose presence in the world betokens the last time. This writer seems to have in mind numerous false human teachers, originally members of, but always alien to the followers of Christ. He seems also to refer to some single arch-deceiver of whom all false teachers are exponents, and in whom is concentrated all antagonism of error and ill will to Christ and his kingdom of truth and grace. There are, however, other Biblical passages in which such antagonisms find acute and culminating expression, and it has been the custom of students to handle all these sections under the study of the Antichrist. Such passages are Matt. XXIV., with its allusions to false prophets and false Christs; 2 Thess. ii., with its "man of sin"; Rev. xi., xii., and xiii., with its dragon and beast; and Daniel vii. and viii., with its figures of the terrible beast and the he-goat. In all these passages a central feature is the mighty opponent and assailant of the people and purposes of God. Clustered about this central personified or personal antagonist of all worshippers of the true God numerous significant features continually recur. Such are names, times, places, forms. These features, variant in themselves, when differently combined by would-be interpreters, yield perplexingly manifold and divergent schemes, as the history of the theme abundantly displays.

The history of interpretation shows four names to have special eminence alongside the name Antichrist, thus: Dragon, Satan, Demon, Belial. The efforts to identify him cluster around typical views. Some deem him to be a form of Jewish antagonism to the Christian faith. Here he is traced to Capernaum, Chorazin, Bethsaida, or to Jerusalem. Frequently he is described as hostile to the Jews, being the counterfeit and foe of the Jewish Messiah. Very many identify him in some way with Rome, naming pre-eminently Nero, or a *Nero redivivus,* or Titus, or Caligula. Quite commonly in the Middle Ages he was seen in Mohammed or in the Turks. Still later some Catholics identified him with Luther. Many emphasized in the Antichrist, whatever his form, the energy or wisdom or very being of Satan or the Dragon. As to times, the diver-

sity of views falls into three classes. Many writers refer all the Biblical allusions to events current at the time of writing. Many others deem the reference to events still future. Still others hold the Biblical teachings to be pre-eminently predictive, but find their fulfilment partial and manifold throughout all Christian history, until their final consummation will mark the end. As to the place of his appearance or activity mention may be found of the Jewish Temple, Jerusalem, Mount of Olives, heaven itself. Closely connected with these central features are various attendant elements such as Michael, his great antagonist and victor; Gog and Magog and the nations which are his minions; the miracles which he works; the two witnesses, Enoch and Elijah, whom he slays; the sign of the Antichrist and the Son of Man; his world dominion; and his final doom. It is manifest that this theme presents a programme of thought and activity of most profound significance, however perplexing its solution. The persistence of its main elements through such a long train of history attests something vital in human life. But its outline is nowhere complete. In recent years the effort to solve its mystery and find its meaning has taken new form and course. Scholars are trying to trace every element of the Antichrist tradition to its historical source. The leaders here are Dieterich, who, in his ‹Abraxas› and ‹Nekyia,› traces parallelisms in Greek myths; Gunkel, who, in his ‹Schöpfung und Chaos,› attempts the same task in old Babylonian mythology; Bousset, who, in his ‹Der Antichrist,› explores post-Christian literature of all types for echoes of the tradition; and Friedländer, who, in his ‹Der Antichrist in den Vorchristlichen Jüdischen Zuellen,› tries to show that every essential trait of the Antichrist is traceable in Jewish circles before the destruction of the temple. The writer last named conceives the Babylonian dragon myth, the Hebrew sons of Belial, the foes of God and his Messiah in Ps. ii., the Zedim of Ps. cxix., the minim of various Jewish writings, the Belial of the Sybilline oracle, the Gnostics, the great antagonist of Daniel, the man of sin in 2 Thess. ii., the false Christ of Matt. xxiv., the Antichrist of John's Epistles, and the dragon of Rev. xi., to be all and severally various phases in one consistent development of the Antichrist idea. These studies, though but the early stages of a mighty task, disclose a commanding theme. For a history of the exposition of 2 Thess. ii. see Bornemann's ‹Commentary› in the Meyer series. For a thorough statement of the Nero speculations see De Wette's ‹Excursus› in his ‹Commentary on Rev. xvii.›; also R. H. Charles, ‹The Ascension of Isaiah,› § 17.

An'ticline, a geological term applied to an up-arching of strata into a fold from whose summit the beds dip outward on both sides. Such a fold resembles an ordinary roof whose sides correspond to the limbs of the fold, while the ridge represents the anticlinal axis. An anticline may be broad with its limbs lying almost flat, or it may be compressed and sharp,— sometimes the strata stand in vertical positions. The anticlinal axis is never perfectly horizontal, and while the fold frequently persists for a distance of several miles, it eventually dies out. The inclination of the axis is called the pitch of the fold. A complex anticline composed of several parallel folds is known as an anticlinorium. The anticline is the complement of the syncline (q.v.), in which the strata are bent into a trough with the axis at the bottom. Both types of folds are the characteristic features of mountain regions. See GEOLOGY; MOUNTAINS; STRATA.

An'ticos'ti, a barren island in the Gulf of St. Lawrence, 135 miles long and 40 miles at its greatest width. The hills in the interior rise to about 600 feet. The climate is severe; while the surface is an alternation of rocks and swamps. It is visited by fishermen in the summer, but there are few inhabitants save lighthouse keepers and official residents. The island, which is attached to the Canadian province of Quebec, has considerable salmon, trout, cod, and herring fisheries, and is a resort for seal- and bear-hunting. In 1895 the island was purchased by M. Henri Menier of France, who had much litigation over the rights of some settlers. A decision in his favor was made in 1900. Pop. 250.

An'ticy'clone, an atmospheric condition characterized by high barometric pressure and outblowing winds,— the opposite of cyclone. An anticyclone extends over a wide area and in the temperate zones usually appears in the west and moves eastward with slow velocity. At the centre of the area the winds move downward, thus bringing the cool, dry air of the upper regions into contact with the earth's surface. Anticyclones are generally accompanied by clear, pleasant weather, but when following a storm in winter they may result in cold waves. See METEOROLOGY.

Anticyra, ăn-tĭs'ĭ-ra, the name of three Grecian towns in Thessaly, Phocis, and Locris, famous for the hellebore which grew in their neighborhood. This plant was in high repute as a medicine, and was thought to have the effect of clearing the brain and curing stupidity; hence the expression of Horace, «*Naviget Anticyram*,» «Let him sail to Anticyra.»

An'tidotes. See POISONS.

An'tiemet'ic, a remedy employed to relieve nausea and vomiting. The choice of an antiemetic depends very largely on the nature of the cause of the nausea and vomiting. There are local antiemetics, acting solely on the mucous membrane of the pharynx, œsophagus, or stomach, and central antiemetics, acting on the nervous system. Among the best local remedies are cracked ice, cold beer, cold carbonated waters, cold champagne, small doses of tincture of iodine, chloroform, belladonna, cocaine, bromides, or chloral. The most reliable general antiemetics are ipecac, opium, and its alkaloids. See EMETICS.

Antietam, ăn-tē'tăm, **The Battle of,** fought on 17 Sept. 1862, in Maryland; sometimes called the battle of Sharpsburg. It was one of the decisive engagements of the Civil War, as it ended the first Confederate attempt at invasion of the North, though tactically a drawn battle. Lee's army of about 50,000 crossed the Potomac near Leesburg, some 30 miles above Washington, and concentrated around Frederick, about 40 miles from Washington and 20 from the Pennsylvania line. When it became known

that Lee had crossed into Maryland Gen. McClellan, in command of the Army of the Potomac, pushed forward several corps with the left on the Potomac.

Meanwhile Lee had ordered a movement on Harper's Ferry (q.v.), in his rear at the junction of the Potomac and Shenandoah. It was a valuable defense against invasion through the Valley of Virginia, but once the Confederates were across it became not only worthless but a trap. Nevertheless Gen. Halleck ordered it held; and Lee grasped the chance of capturing its defenders (with the Martinsburg outpost) and opening up his communications at once. This involved dividing his army for days, with a much superior force two or three days' march off, but he gauged his foes justly enough to take the risk. The operation was effected with great skill and success and accurate co-ordination; but it took longer than Lee expected, and a mischance befell which should have undone him. A copy of his order fell into McClellan's hands on the 13th, telling him of the dividing of that army not far off, its object, the position of the separate detachments, and the premium on expedition; but the opportunity was lost to the Federals through McClellan's unexplained delay in giving orders for an advance.

Lee, advised by the night of the 13th at Hagerstown that McClellan was advancing on South Mountain, marched back to resist his advance but was defeated and on night of 14th fell back to Sharpsburg, a few miles southwest of Boonsboro, as the nearest strong position for his Harper's Ferry detachments to rejoin him, as on the flank and rear of any force menacing Maryland Heights which they occupied, and a very defensible position in itself. Six or seven miles above the Heights the Potomac receives Antietam Creek, flowing through a ravine, with banks rising on the west to a low ridge having wooded patches, ledges, stone and wooden fences, cornfields, etc., as natural bulwarks, and sloping on the western side to the Potomac. Two and a half miles above the confluence a sharp eastern bend of the Potomac brings it within 2½ miles of the Antietam; and at about the centre of the peninsula thus formed lies Sharpsburg, in a hollow on the western slope. Lee's line, about three miles along the crest, was to rest one flank on an elevation near the Potomac, with the village in the rear centre, and a secure retreat by the Shepherdstown ford of the Potomac in the rear.

The Union troops having forced South Mountain (q.v.) by two sharp battles on the 14th, the main body issued therefrom next morning, marched the eight miles to Antietam Creek, and formed in line along the east ridge. By afternoon some 50,000 troops were opposed to about 30,000 under Lee, with Longstreet and D. H. Hill. Late in the afternoon McClellan came up, was received with immense enthusiasm, and decided that it was too late to attack that day. On the 16th Jackson and Walker had joined Lee with fully 10,000 more. The chance of splitting the Confederate army being now lost, McClellan waited for his ammunition and supply trains to arrive and ordered no attack save of Hooker's corps on the right late in the afternoon. A list of divisions and commanders now becomes requisite for brevity and intelligibility in describing the battle.

Union Army.

Right Wing.— Jos. Hooker. First Corps: Jos. Hooker; three divisions; commanders, Abner Doubleday, J. B. Ricketts, G. G. Meade.

Centre.— E. V. Sumner. Second Corps: E. V. Sumner; three divisions; commanders, I. B. Richardson, John Sedgwick, W. H. French. Twelfth Corps: J. K. F. Mansfield; two divisions; commanders, A. S. Williams, G. S. Greene.

Left Wing.— A. E. Burnside. Ninth Corps: J. D. Cox; four divisions; commanders, O. B. Willcox, S. D. Sturgis, I. P. Rodman, J. D. Cox (in the battle, E. P. Scammon). But Burnside refused to take personal command of the corps because, while he had previously commanded the right wing with the First and Ninth under him on the day previous, the former (Hooker's) had been taken from him and made an independent command; he feared that acquiescence would lose it to him permanently, and merely transmitted orders through Cox. The corps therefore had a technical commander who would not exercise initiative and a real one who could not.

Reserve.— Fifth Corps: Fitz-John Porter; two divisions; commanders, Geo. Morell, Geo. Sykes. Sixth Corps: Wm. B. Franklin; two divisions; commanders, H. W. Slocum, W. F. Smith. Temporarily attached, D. N. Couch's division from the Fourth Corps. This came from Pleasant Valley during the forenoon, and portions were used as reserves. Couch's division did not reach the field until after dark of 17th.

Cavalry.— Alfred Pleasonton.

Confederate Army.

First Corps.— Jas. Longstreet. Five divisions; commanders, Lafayette McLaws, R. H. Anderson, D. R. Jones, J. G. Walker, J. B. Hood.

Second Corps.—T. J. ("Stonewall") Jackson; four divisions; commanders, I. R. Jones A. R. Lawton, A. P. Hill, D. H. Hill.

Some crucial points of the battle-ground must be noted. The heart of the fighting was north and east of a Dunkard chapel of red brick, a mile north of Sharpsburg, on the west side of the Hagerstown turnpike, with tall woods free from underbrush to the west and north (the "west woods"), and elevated ground with ledges, hollows, etc., to the north (Nicodemus' Hill) and west. Next to and across the road was open ground, with a field of high strong corn opposite the north end of the west woods, and then the "east woods," also interspersed with rocks, with a commanding ridge running south, cut by a sunken road (the "Bloody Lane") running east from the turnpike.

On the morning of the 17th Fitzhugh Lee's cavalry brigade and some artillery formed the extreme Confederate left, holding Nicodemus' Hill; next Jackson, Jones' division, in and in front of the west woods, and the bulk of Ewell's division on Jones' right, in the open ground east of the Hagerstown turnpike; D. H. Hill on the left centre. Longstreet formed the centre and right, and A. P. Hill on the extreme right came up in the afternoon. Hood on the left was relieved by Ewell the night before, and formed a reserve near the Dunkard church. McLaws withdrew from Maryland Heights on the 15th and 16th, crossed and recrossed the

Potomac, and rejoined Lee early on the morning of the 17th, also taking post on the left.

On the Union side, Hooker having crossed the Antietam, Mansfield also crossed in the night and took position in the rear. Sumner and Burnside remained east of the stream. The Confederates rightly inferred from the Union dispositions that the force of the attack was to be on their left, and strengthened it accordingly: 10 of the best brigades in their army were placed in the west and east woods and south of the cornfield. They had nearly 40,000 men in the battle; the Union troops engaged numbered about 55,000. This superiority was little enough against the immense advantages of the Confederate position; and even so, it was frittered away in a series of disconnected attacks, which left a large part of the Confederate force usable at one time against 15,000 Federal troops at most.

1. Hooker, lying nearly a mile north of the Dunkard church, moved down against Jackson early in the morning; reported strength 14,856; actual, under 10,000. The objective point was the elevated ground about the church. The march had its right on the turnpike and its left along the west edge of the east woods, from which a withering fire checked it a little; the right was raked by a flanking fire from the west woods. At length the line gained the southern edge of the cornfield and engaged the Confederates in the open ground about 220 yards distant. Under the storm of bullets, shot, and shell that rained upon them, they broke and fled through the corn, to re-form in a hollow beyond; the Confederates assailed the Union lines in turn, and in turn were riddled by a concentrated fire that drove them back. Again the Union troops advanced, to be forced back in disorder; and again the Confederates followed, to break and fly. This was one of the most frightful carnages of the Civil War: Jackson's famous "Stonewall" division was nearly annihilated, more than half of two brigades killed or wounded and more than a third of another, and all the regimental commanders but two. On the Union side 1,051 in Rickett's division were cut down, a third of its whole number, and two brigades lost over 40 per cent; Hooker was wounded and was succeeded by Meade. Hood and D. H. Hill now came up to replace Jackson's losses; and Hooker's remnants slowly withdrew northward just as the advance of the Twelfth came up, though Ricketts still held the edge of the east wood.

2. Mansfield was mortally wounded while deploying his troops about 7 A.M., and A. S. Williams took command: reported strength, 10,126; actual, about 7,000. Marching more obliquely to the road, facing southwest, they cleared the cornfield, and about 8.40 A.M. drove the Confederates across the turnpike and into the west woods.

3. The Second Corps, under Sumner, had not received orders to march till 7.20, after the First was crippled and the Twelfth in the thick of action; and Richardson's waiting for Morell's division of the Fifth corps to occupy the ground he vacated caused him to be an hour later still. Sedgwick's division, with Sumner at the head, went first, French following; each with perhaps 5,000 men; they crossed the Antietam, moving west by north, till the centre was nearly opposite the Dunkard church; then deploying, faced west, French forming on Greene's left. Sedgwick passed through the east woods and the cornfield; advanced swiftly in three lines, no regiments in column or ready to face to either flank if attacked, swept by Greene's right and pressed through the west woods with left on the church, to the western edge and a wood road along it. Meantime McLaws and Walker with six brigades had come up, one brigade had been drawn from the right to reinforce Early's forces of Ewell's division; and all fell upon Sedgwick's left flank and rear. Nearly 2,000 Union soldiers were struck down at a blow without a chance to retaliate; this division lost 2,255 men in all, more than 40 per cent of its entire number, including Sedgwick severely wounded. Sumner tried to change front, but the lines broke and scattered northward, sweeping away everything in their rush, and only re-formed on the north hill where Meade and the First corps had taken refuge. A brigade of the Twelfth came up to help, but lost a third of its number, one regiment losing 60 per cent. The right of the Confederate attacking line crossed the turnpike at the Dunkard church and made two assaults upon Greene's position east of the church, and were repulsed with great slaughter, and Greene, making a counter charge, entered the woods beyond the church. Greene held this position until noon, when the Confederates attacked both his flanks and drove him from the church.

Meantime W. F. Smith of Franklin's corps had come on the field. Hancock (then one of his brigadiers) obtained a regiment from Sumner, took position opposite the woods, drove away the approaching Confederate skirmishers, and silenced their batteries. A second brigade was placed on his left, and with heavy loss advanced to near the church; but on sending for his reserve brigade to support it he found it had been ordered away to support French. The latter moving to the left south of the east woods, over the farm lands, drove back D. H. Hill's skirmishers to his main line in the sunken road, where he engaged him over an hour, when he was joined by Richardson. Here a long and sanguinary conflict ensued: the Confederates turned the "Bloody Lane" into a rough fortress with fence rails, and before carrying it the Union divisions had lost near a third of their total, one regiment losing 60 per cent. They had won the position by perhaps 1 P.M., and shortly afterward French's troops were relieved by a brigade of Smith's division. Richardson withdrew his men to the ridge, and about that time was mortally wounded and succeeded by Hancock. This practically ended the operations on the Federal right, and indeed the battle of Antietam so far as it had any tendency to change the *status quo*. When Richardson's line had been withdrawn, there was a vigorous contest of artillery. Meagher's brigade took the centre, and somewhat less than two regiments came from French to aid Richardson's division. Despite the application for artillery for the division, none had been obtained. The length of the Union line made it impossible that more than one line of troops be formed; and so far advanced was this line that a part of it was continually swept by the fire of the batteries on the Confederate left, these batteries being protected by the west woods. An attack on the Union left was successfully repulsed by Hexamer's battery (obtained from Franklin) and Battery I, First artillery.

4. Between 4 and 5 P.M. a regiment of Franklin's corps was ordered to drive away some skirmishers of Hill's division south of the Bloody Lane and succeeded at the cost of half its force.

5. The battle which Franklin was not allowed to fight must be mentioned. It has been noted that Smith's action was paralyzed by taking away a third of his force for service elsewhere. About noon Slocum, with the other division, reached the field, and two brigades were at once formed in line to carry the woods around the church; but again the reserve brigade was ordered off. Franklin urged with all his strength to have a grand assault made with his whole corps on Lee's centre, crippled and worn out with half a day's fighting and slaughter. With relatively fresh troops, and French and Richardson to aid, it is most probable that few Confederates would have crossed into Shepherdstown. But Sumner refused to permit the movement; still, Franklin was so urgent that he referred the decision to McClellan, but with so strong a veto that McClellan deferred to him and sanctioned the refusal. Both credited Lee with double or treble his actual numbers, and considered the terrible resistance, not as a proof that it could not be continued, but that any force which assailed him went to destruction. This refusal forms another of the might-have-beens of the battle, with some peculiarly poignant personal tragedy involved.

6. The action of the left under Burnside is an even more acute personal question. His peculiar position has already been noted. About 7 A.M. he received an order to hold himself in readiness to carry by assault a stone ridge across the Antietam about a mile southeast of Sharpsburg. About 10, when the First and Twelfth Corps and Sedgwick's division were out of the fight, he received another order to carry the bridge and the heights beyond, and advance on the rear of Sharpsburg. He turned it over to Cox, who ordered a brigade to storm the bridge, Rodman to cross by a ford one third of a mile below, and the two to carry the heights and unite there. At best this could not be done in a moment, and the movement seems a covering rather than an aggressive one. But Crook missed the bridge and could not get back to it under fire: Rodman missed the ford and was two hours or so crossing under fire; a fresh storming party finally carried the bridge, Crook crossed some companies above and others at the bridge, and Rodman and the rest united about 1 P.M., when the battle on the right was virtually over. Meantime Sturgis' division had run out of ammunition and was reported unfit for duty; it was replaced by Willcox's (Burnside assisted in this), and at 3 P.M. the corps was again ready to move, though much damaged by the constant Confederate artillery fire. The right wing broke Jones' division and gained the suburbs of Sharpsburg; but the left was strongly checked, and the two wings grew widely separated. Meantime A. P. Hill came upon the field, having marched 17 miles in seven hours. He took Rodman's division in its undefended flank (the second misadventure of the sort that day), and Rodman was killed, while a concentric fire mowed down his men. The losses of the corps were 2,349; a fearful total, almost exactly those of Sedgwick's division. A panic was averted by Scammon, who changed front and checked Hill for a little; Cox called up Sturgis and made head for a while: but at length the corps was obliged to withdraw to the cover of the hills that border the Antietam.

The Union losses were 12,410: 2,108 killed, 9,549 wounded, and 753 missing. More men were killed on this one day than on any other of the Civil War. The Confederate losses were never known with exactness; but as 2,700 of their dead were counted and buried by the Union forces, and many had previously been buried by their comrades, the total cannot have been less than the Federal. The next day Lee retreated across the Potomac unopposed: the failure to pursue him was one of the grievances against McClellan later, but most of his generals concurred with him. Although Lee had escaped destruction, he had none the less failed in his campaign.

(The Count of Paris' 'History of the Civil War,' Vol. II., 1876, is from the standpoint of a strong admirer of McClellan, whose staff he was on; F. W. Palfrey's 'The Antietam and Fredericksburg,' 1882, from a lieutenant-colonel of Sedgwick's division, is sharply critical of nearly all the Union generals; John C. Ropes' 'Story of the Civil War,' Vol. I., 1894, is from a noted military critic; Michie's 'General McClellan,' 1901, is from a distinguished engineer officer and professor at West Point; the account in 'Battles and Leaders of the Civil War' (N. Y. 1884-8), is by Gen. J. D. Cox. Consult also, 'McClellan's Own Story' (1866), and Lives of Gen. McClellan and the general officers.)

FORREST MORGAN,
Connecticut Historical Society.

An'tifeb'rin, a trade name for the substance known to chemists as acetanilide (q.v.).

An'ti-Fed'eralists, the first political party in the United States after the separation from Great Britain. The loyalists having been expelled, there was no issue to divide upon till the question of replacing the loose Confederation with a stronger bond came up. The representatives of commerce and capital, and the mass of the educated classes, favored ratifying the Constitution; those who feared that a strong government meant a disguised new kingship, the local leaders who wished to retain pre-eminence, and the conservatives who thought no evils comparable to those of change, opposed it. The names were in direct opposition to the facts, the Federalists striving to turn the federation into a unified nation, the Anti-Federalists endeavoring to preserve a loose disintegrated federation. The victory of the superior classes was overwhelming, one great cause being that the men who were later the leaders of the Anti-Federal opposition were Federalists (q.v.) for the time being, as they felt that the existing condition of affairs was intolerable. In the organization of the first Congress and executive under the Constitution, the Federalists proper held every post but three, and even those were not technically «anti» till later. In this Congress, though there was much individual opposition to the Federalist measures, it was unorganized, and the Anti-Federal spirit could hardly be said to animate a body. Hamilton's scheme for clearing up the public debt was the first point of division. The payment of foreign debts was carried unanimously; that

for paying the Continental debt at par was opposed by Madison and others except as to original holders; that for assuming the State debts was bitterly fought as defaming the States' solvency and as buying the support of capital for the Federal government, was carried by only five votes, reconsidered and beaten by the seven votes of the new North Carolina just admitted, again reconsidered and carried by Jefferson's log-roll of establishing the new capital on the Potomac. His national-bank scheme (1791, opposed by Madison in the House and Jefferson and Randolph in the Cabinet) and his tariff and excise schemes also excited a growing hostility from this element, which by the time of the 2d Congress (1 Oct. 1791) was becoming a new strict-construction party; no longer opposed to the Constitution as such, but opposed to extending its powers beyond the most literal interpretation of its terms. Jefferson, Madison, and Randolph were now the chiefs of the new party in public office; but Jefferson disclaimed being an Anti-Federalist, based his policy on love of «republicanism,» as sympathizing with the French revolution, and called the Hamiltonians «monarchists.» The Republicans and Anti-Federalists comprised the same elements, however, and were based on the same natural division, and Washington's proclamation of neutrality in the European conflict in 1793 fused them into one as the Republicans, later into the Democratic-Republican party.

Antigo, Wis., county-seat of Langlade County, a northern county of the State. It is situated in the southwestern portion of the county, 96 miles north-northwest of Oshkosh and 207 miles northwest of Milwaukee; and it is on the Spring Brook River and the Chicago and Northwestern railway. It is the commercial centre of an agricultural section of considerable importance, and of a timber region which has contributed largely to Wisconsin's position in marketed forest products. There are located several extensive manufactures of various sorts, including chair, hub, broom-handle, excelsior, veneer, and other factories; also foundries, breweries, railway-shops, and flour, planing, and saw mills. Antigo was settled about 1878, and in 1884 was incorporated. Under the provisions of a general law of Wisconsin, its government is administered by a mayor, elected for a two-years' term, and a municipal council. Pop. (1890) 4,424; (1900) 5,145.

Antigua, antē'gwa, one of the British West Indian islands, situated lat. 17° 6′ N. and lon. 61° 45′ W., about 50 miles east of Saint Kitts and the same distance north of Guadeloupe; area 108 square miles; dependencies Barbuda and Redonda, which have an area of 62 square miles; population including those dependencies 34,971 (mainly negroes) in 1901, as compared with 36,819 in 1891; the principal island of the Leeward group; residence of governor and his staff; port and chief town, Saint John; the chief products, sugar and pineapples. See ANTILLES; WEST INDIES.

Antilles, ăn-tĭl'lēz, the name given both to the group of large islands forming the northern limit and the chain of small islands forming the eastern border of the Caribbean Sea. Practically all of the West Indian Islands except the Bahamas are thus included. The Greater Antilles (Cuba, Jamaica, Haiti, and Porto Rico) have about 3,700,000 inhabitants, or nearly three fourths of the entire population of the West Indies. The Lesser Antilles extend toward the southeast in a curved line from Porto Rico to the coast of Venezuela and follow the line to that coast from the Orinoco delta westward to the Gulf of Maracaibo. Their total area is 5,557 square miles, and their population is approximately 1,230,000.

The following classification shows the natural grouping of the Lesser Antilles, with the area (in square miles) and the population of the islands in each of the groups:

1. *Virgin Islands.*— St. Croix (A. 74, pop. 18,430); St. John (A. 21, pop. 950); St. Thomas (A. 23, pop. 32,786); Tortola (A. 58, pop. 5,000); Anegada (A. 20); Virgin Gorda (A. 176). 2. *Outer Chain of Caribbee Islands.*— Anguilla (A. 35, pop. 3,699); St. Martin (A. 38, pop. 3,724); St. Bartholomew (A. 5, pop. 2,650); Barbuda (A. 62, pop. 639); Antigua (A. 108, pop. 34,971); Désirade (A. 10, pop. 1,400); Maria Calante (A. 65, pop. 13,850). 3. *Inner Chain of Caribbee Islands.*— Santa Cruz (A. 74, pop. 18,430); Saba (A. 5, pop. 2,065); St. Eustatius (A. 8, pop. 1,613); St. Christopher (A. 65, pop. 30,867); Nevis (A. 70, pop. 13,087); Montserrat (A. 32, pop. 11,762); Guadeloupe and dependencies (A. 600, pop. 167,000); Dominica (A. 290, pop. 26,841); Martinique (A. 400, pop. before volcanic eruption of 1902, about 187,000); St. Lucia (A. 245, pop. 46,671); St. Vincent (A. 131, pop. 41,054); Grenada (A. 133, pop. 54,000). 4. *Barbados.*—(A. 166, pop. 189,000). 5. *South American Islands.*— Tobago (A. 114, pop. 20,463); Trinidad (A. 1,754, pop. 248,804); Buen Ayre (A. 95, pop. 4,399); Curaçao (A. 210, pop. 28,187); smaller islands (A. 470, pop. 40,000).

English geographers call the northern part of the chain of Lesser Antilles «The Leeward Islands,» the capital of the Leeward government being on Antigua, and the southern half «The Windward Islands,» Grenada being headquarters of the Windward government. The present holdings of England, France, Denmark, and Holland in the Lesser Antilles are reminders of the early struggles of the European nations to win supremacy in the New World; for the West Indies were commonly regarded up to the end of the eighteenth century as the most valuable part of America, and these islands were the chief battle-ground of the rival powers. Admiral Rodney's victory over the French admiral De Grasse, 12 April 1782, gave England her commanding position in this region. Her possessions constituting several distinct colonial governments, include the Virgin group (except the Danish Islands, St. Thomas, St. Croix, and St. John); all below the centre of the chain, namely, St. Lucia, St. Vincent, Barbados, Grenada, Tobago, and Trinidad; the important island of Dominica, etc. The Virgin Islands are important because they command the deep-water Anegada passage between the Atlantic Ocean and the Caribbean Sea; and the only deep harbors (except St. Thomas) in the Lesser Antilles are in Trinidad and St. Lucia. The French retain among their possessions the somewhat larger islands of Guadeloupe and Martinique in the centre of the chain. The Dutch, in addition to Curaçao and Buen Ayre,

have a few small islands below the Anegada Passage, the whole width of the Caribbean Sea intervening. The economic history of the islands of the Lesser Antilles is simple. Nearly all of them derived their wealth in the past from sugar culture, and with the decline in the price of sugar have sunk into poverty. Meanwhile, the black population has crowded out the Caucasians.

MARRION WILCOX,
Authority on Latin-America.

An'ti-ma'sonry, in United States history, (1) the widespread hostility to the Freemasons, as an order whose oaths were contrary and superior to public duty and private morality, excited by the fate of William Morgan (q.v.) in 1826. He was a broken Virginian, who had settled in Batavia, N. Y., about 1824, as a mason by trade, and professing to be a Royal Arch Mason; and in the summer of 1826 was reported to be writing a book to expose the secrets of Freemasonry, to be printed at a local newspaper office. Though the Masons were naturally indignant and distressed, the other citizens regarded it as a catchpenny scheme, and had Morgan remained in view probably Masonry would have suffered little damage,— certainly none if the Masons had merely denied his statements, for his word would have carried no weight. But, unluckily, just at this time suits against him for debt began suddenly to multiply, and bail was either refused or disregarded. Finally on 11 August he was taken to Canandaigua, 50 miles away, on a charge of theft; was released, but at once rearrested for debt; and on the next night, being again released, he was at once seized and never reappeared. The public at once connected this with the Masonic exposure and threats, and vigilance committees were shortly organized which traced him beyond question, in the hands of abducting parties, to Fort Niagara, an unoccupied United States post at the mouth of the Niagara River; the last ever certainly known of him, though other statements made it seem probable that he had been murdered and thrown into Lake Ontario. The excitement, increased by the belief that prominent Masons obstructed the investigations, was fanned into flame by the appearance, a few weeks later, of the first part of Morgan's book, the other parts ultimately being published also; entitled 'Illustrations of Freemasonry, by One of the Fraternity Who Has Devoted Thirty Years to the Subject'; reprinted under various titles, as 'Light on Masonry,' 'Freemasonry Exposed and Explained,' etc. Along with a mass of dreary "ritual" for "working the degrees," of no moment even if true, and its betrayal a scandalous violation of good faith, it included some passages which if true would have obligated him to make them known at once on joining: such as an oath requiring Masons to place their duty to a brother Mason before their oaths in court; and others pronouncing dire vengeance (graduated according to the degree thus betrayed) on Masons who should reveal the secrets of the order, and obligating every "brother" to make it his business to execute the threat. The denials of the Masons were not thought categorical enough. The alleged agents in the abduction were put on trial between January 1827 and 1830, and several were convicted and sentenced, some pleading guilty to save examination as to conspiracy. They could not be held for murder, but popular judgment charged that crime to the fraternity if not to the individuals. Very soon Anti-Masonry had become the one issue of the day. Candidates for local office who refused to withdraw from the order were heavily "scratched" at elections, and great numbers of lodges had to give up their charters and dissolve. From New York the feeling spread through the Union, and more than 3,000 lodges surrendered their charters before the storm blew over. The governor of New York and a large number of the leading officials and prominent public men were Masons, as now; but in the campaign of 1828 the National Republicans dared not nominate any who belonged to the order. None the less the Anti-Masons formed a regular party, holding a convention at Utica and nominating Solomon Southwick for governor. Wm. H. Seward, Millard Fillmore, and Thurlow Weed first came forward as Anti-Masonic candidates. A body was conveniently found in Niagara River and said to be Morgan's, though of course unrecognizable; and Weed is credited with having replied, when questioned as to its authenticity, that it was "a good enough Morgan till after election." The ticket polled 33,345 votes out of 276,583; but it polled some 70,000 in 1829 and 128,000 in 1830, gradually absorbed the National Republican party in the State, and became the chief anti-Democratic organization. This is the most singular feature of the whole movement; for the National Republicans, like the Whigs and Republicans later, were distinctly the party of the upper business and professional classes, which were the very ones who formed the strength of the Masons. Yet the same result obtained everywhere: doubtless it was due to the accidental fact that Jackson, the idol of the Democracy and then President, was a Mason. A national convention was held in 1830 to organize a national party; and in September 1831, in order to force Clay, who was a Mason, out of the field, it held a convention (in Baltimore) before any of the other parties, and nominated William Wirt of Maryland and Amos Ellmaker of Pennsylvania for the Presidency. The National Republicans, however, supported Clay, and in the election of 1832 Wirt received only the electoral vote of Vermont. The party took no further national action, and with the National Republicans was soon absorbed in the new Whig party, though it retained force enough to compel the Whigs to discard Clay for Harrison in 1833 and 1839. In Pennsylvania, however, allied with the Whigs, it survived till about 1840 and elected a governor, Joseph Ritner. (2) Another Anti-Masonic body was formed in 1868 as the National Christian Association, at Pittsburg, Pa., though hostility to Masonry was only one of its tenets; it renamed itself in 1875 the American Party (q.v., No. 2), and entered politics. It opposed Freemasonry as "false religion and false politics," and urged the prohibition of oath-bound lodges as acknowledging another government than that of the United States.

Bibliography.— For Morgan, see Morris, 'History of the Morgan Affair' (1852); Greene, 'The Broken Seal, or the Morgan Abduction and Murder' (1870). For political results see Hammond, 'Political History of New York'; Hopkins, 'Political Parties' (1900).

An'ti-Mission Baptists (their own title is "Old School Baptists"), an American sect founded about 1835, who do not believe in Sunday-schools or theological seminaries, holding that salvation does not depend upon human instrumentalities, but upon divine grace alone.

Antimonan, ăn'te-mō-năn', a seaport town of Luzon, Philippine Islands, province of Tayabas. It is situated on Lamon Bay, about 100 miles southeast of Manila. Pop. about 11,000.

An'ti-Monop'oly Party, an American political organization which in 1884 nominated for the Presidency Benjamin F. Butler (q.v.), on a platform advocating election of United States senators by popular vote, an income tax, the repeal of all tariffs, and the prohibition of land grants to corporations. It united with the Greenback Labor party, the combined vote reaching 130,000 votes in the November election of 1884.

An'timony, the name of one of the metallic elements. It is found in nature in the metallic state, but its chief commercial source is the mineral stibnite, which is a sulphide of antimony (Sb_2S_3). Stibnite was known in very early times. It has been used by the women of the East for many centuries for painting the eyebrows and eyelashes and giving lustre to the eyes. Before the discovery of the metal itself, stibnite was called "antimony," and it appears that the paint used by Jezebel (2 Kings ix. 30) was finely ground stibnite. The Arabs called this face-paint *al-Koh'l* (compare ALCOHOL). The origin of the word "antimony" is not known. There is a legend that certain monks were once poisoned by it, and that the name is derived from *anti*, "against," and *moine*, "a monk"; so that *antimoine*, or antimony, would mean "monk's bane," or something of that sort. This derivation, however, is entirely fanciful. The first distinct mention of the metal itself is made by Basil Valentine, who gives a process for extracting it from stibnite, though he does not claim to have discovered it. Several methods for extracting it are now in use, chief of which is the following: Two parts of stibnite are melted with one part of thin scrap iron, in plumbago crucibles. Leaving the antimony the sulphur combines with the iron, so that sulphide of iron and metallic antimony result, the iron sulphide floating as a slag. The crude antimony so obtained is next melted with a small amount of sulphate of soda and a little of the slag obtained from the operation next to be described. By this means the metal is purified somewhat. It is then cast into molds, and when cold is broken up into small pieces, to prepare it for the third operation, which is called "melting for star metal." This last-named process consists in melting 60 parts of the broken metal with two parts of pearlash and five parts of slag from a previous operation of the same kind. The resulting metal or regulus is poured into square molds, into which some slag has first been allowed to run, and is cooled slowly while still covered with slag. If the metal is of good quality, the resulting blocks will have a stellated or crystalline surface. The total consumption of the metal is probably as much as 4,000 tons per annum, nearly all of which is smelted and refined in England. Ores of antimony occur in Mexico, California, Nevada, New Brunswick, France, Australia, Japan, China, Italy, Spain, Portugal, Corsica, and many other parts of the world.

Antimony is a brilliant, bluish-white, brittle, crystalline metal, with a specific gravity varying from 6.72 to 6.86. It melts at about 800° F., and if protected from the air boils at a white heat. At ordinary temperatures it is not acted upon by air or water, but it oxidizes quickly when melted, and at a red heat burns at a brilliant white flame, and can decompose water. It expands upon solidifying, and imparts this property to its commoner alloys. Its co-efficient of expansion is about .0000064 per degree F. The tensile strength of cast antimony is about 1,000 pounds per square inch of sectional area. It is a comparatively poor conductor of heat and electricity, its thermal conductivity being only about one twenty-fifth of that of silver; its electrical resistance is 0.488 of that of mercury at 32° F., and 0.704 that of mercury at 212° F. Its chemical symbol is Sb (from the Latin word ***stibium***), and its atomic weight is sensibly 120. It is diamagnetic; that is, a sphere made from it is repelled by a magnet, though the repulsion is hardly comparable in magnitude with the force of attraction that a magnet exerts upon iron. It also has marked thermo-electric properties, and is used in the laboratory in the construction of thermopiles. Antimony forms valuable alloys with other metals, and this is its most important use in the arts. Type metal is an alloy of lead, antimony, and tin, with sometimes a little copper. The tin adds toughness, while the antimony gives hardness and causes the alloy to expand upon solidifying, giving an accurate cast of the letter.

An'timony-pois'oning, a variety of poisoning formerly more common than at present. The mortality is about 40 per cent. The symptoms of acute poisoning resemble closely those of arsenic-poisoning. There is sudden acute gastric pain, with nausea and vomiting, pressure in the breast, and intense sense of anxiety. This is followed by colicky pains and diarrhœa. The pulse becomes small and frequent, later retarded; the respirations diminish in number, the skin is cyanotic, the temperature sinks, and coma and convulsions lead to death. If vomiting develops early, before time has elapsed to permit of the absorption of a large amount of the antimony salt, death is less likely to occur. The treatment should include washing out the stomach, inducing of vomiting, and the use of tannic acid compounds.

Anti-Nebraska Party. See KANSAS-NEBRASKA BILL.

An'tino'mianism, the name applied to the doctrine that the dispensation of grace as set forth in the New Testament frees the Christian from the claims and obligations of the moral law as presented in the Old Testament. In the early Church there were antinomian tendencies due to an over-emphasis of faith in opposition to works. This is especially so in some of the Gnostic systems, where faith and love are so emphasized that moral matters appear indifferent, and the contradictions between the law and the gospel are regarded as irreconcilable. Antinomianism marked many of the mediæval sects, but reached its fullest development in the

Reformation period. In Luther's emphasis on the doctrine of justification by faith he had used expressions which might be understood to indicate opposition between the law of Moses and the gospel, as though with the establishment of the gospel the law of Moses was no longer of any value. But when Luther carefully expressed himself on this point, as he did in his instruction to the Saxon preachers in 1527, he gave to the teachings of the Old Testament their proper place in the Christian life. This was disputed by Agricola, and a controversy broke out between him and Luther, in which he treated Luther's most extreme statements in regard to faith as though they were to be taken literally. His follower Amsdorf went as far as to say that good works were detrimental to salvation. In England there were Antinomians in the various sects in the time of Cromwell. They were high Calvinists and claimed that, as the elect cannot fall from grace, any act performed by them, however sinful it may seem to men, is not in reality sinful.

An'tioch (Latin, *Antiochia*), the ancient capital of the Greek kings of Syria; on the Orontes; about 21 miles from the sea. It was founded by Seleucus Nicator in 300 B.C., and named after his father Antiochus. The first inhabitants were brought from Antigonia, founded by Antigonus in 307. It was famed for the splendor of its public buildings, the Seleucid monarchs having vied with each other in embellishing their metropolis, and the Roman emperors having also done much to adorn it. It was called the "Queen of the East" and "The Beautiful," and was advantageously situated for trade, being easily approached by the caravans of the East, and through its port Seleucia having maritime communication with the West. The city is frequently mentioned in the New Testament, and it was here that the disciples of our Saviour were first called Christians (Acts xi. 26). In 64 B.C., on the breaking up of the kingdom of Syria, it was captured by Pompey; in 266 was captured by the Persians under Sapor; and in 538 was thrown into a heap of ruins by Persians under Chosroes. It was restored by the emperor Justinian, but never quite recovered from this last blow. In the first half of the 7th century it was taken by the Saracens and remained in their possession for upward of 300 years, when it was recovered by the Greek emperor Nicephorus Phocas. In 1098 it was taken by the Crusaders. They established the principality of Antioch, which lasted till 1268, when it was taken by the Mameluke sultan of Egypt. In 1516 it passed into the hands of the Turks. The modern Antioch or Antakieh is a poor place. It has some manufactures of silk stuffs, leather, and carpets, and has some trade in these articles and in goat's wool, beeswax, etc. The population is not far from 20,000.

Antioch College, an American coeducational institution in Yellow Springs, Ohio, founded in 1852 with Horace Mann as its first president. It has an endowment of over $100,000; its grounds and buildings are valued at $250,000; and its library contains 7,000 volumes. In 1901 it had 16 instructors and 177 students, its graduates numbering 2,260.

Anti'ochus, the name of 13 kings of Syria: 1. ANTIOCHUS I., or Antiochus Soter, son of Seleucus: b. about 324 B.C.; d. 261 B.C. He succeeded his father in 280 B.C. and disputed Macedonia with Antigonus Gonatas, but finally relinquished it to him. During the greater part of his reign he was engaged in a protracted struggle with the Gauls, by whom he was killed in battle. 2. ANTIOCHUS II., or ANTIOCHUS THEOS, who succeeded his father Antiochus I. Weakened by war with Egypt, he lost Parthia and Bactria by revolt. He was murdered in 246 B.C. by Laodice, his wife, whom he had put away to marry Berenice, daughter of Ptolemy. 3. ANTIOCHUS III., THE GREAT, grandson of Antiochus II., who succeeded his father Seleucus Callinicus in 223 B.C. at the age of 15. He made war on Parthia and Bactria, but was compelled, after a long war, to recognize the independence of these kingdoms. He next invaded India, where he remained for seven years (212–205 B.C.). Invading Asia Minor and crossing to Europe he took possession of the Thracian Chersonese. Antiochus gained an important ally in Hannibal, who had fled for refuge to his court; but lost the opportunity of an invasion of Italy while the Romans were engaged in war with the Gauls, of which the Carthaginian urged him to avail himself. In 192, at the request of the Ætolians, he crossed to Greece, but was defeated by the consul Acilius Glabrio and returned to Asia. He was defeated by Scipio near Magnesia, 190 B.C. Peace was granted him in 188 B.C. on the cession of all his dominions west of Mount Taurus, with a heavy indemnity. He also engaged to surrender refugees of his court, but he allowed Hannibal to escape. He was killed while plundering a temple in Elymais. 4. ANTIOCHUS IV., EPIPHANES, son of Antiochus the Great; d. 164 B.C. He is chiefly remarkable for his attempt to extirpate the Jewish religion. 5. ANTIOCHUS V., EUPATOR, son of Antiochus IV., who reigned from 164 B.C. to 162 B.C. 6. ANTIOCHUS VI., THEOS, ruled for three years, 145–142 B.C. 7. ANTIOCHUS VII., SIDETES, the son of Demetrius I.: b. about 164 B.C.; d. 129 B.C. He defeated the Parthians in several battles. 8. ANTIOCHUS VIII., GRYPUS, son of Demetrius II. He ruled 125–113 B.C. and 111–96 B.C. and was slain by Heracleon in the last named year. 9. ANTIOCHUS IX., CYZICENUS, son of Antiochus VII. Defeated in battle against Seleucus V., he committed suicide in 95 B.C. 10. ANTIOCHUS X., EUSEBES, son of Antiochus IX. He reigned but three years and was obliged to flee to Parthia in 92 B.C. 11. ANTIOCHUS XI., EPIPHANES, son of Antiochus Grypus. He reigned 95–93 B.C. and was drowned in the Orontes. 12. ANTIOCHUS XII., DIONYSUS, 85 B.C. He was killed in battle with the Nabatoreans. 13. ANTIOCHUS XIII., ASIATICUS, the son of Antiochus X., and the twentieth of the Seleucidian dynasty. Beginning his reign in 69 B.C. he was deposed by Pompey in 65 B.C.

Antiphlogis'tic, a term applied to medicines or methods of treatment that are intended to counteract inflammation, such as bloodletting, purgatives, diaphoretics, etc.

Antiph'ony ("alternate song"), a term denoting in the services of the Christian Church, a psalm, chant, or other composition, sung by

two parties in alternation, as by two choirs or parts of a choir, or first by a single voice and then repeated by the whole choir. The Roman Church applies the term antiphony in a restricted sense to a series of "words or verses prefixed to and following a psalm or psalms, to express in brief the mystery which the Church is contemplating in that part of her office." The practice of alternate singing formed a part of the old Jewish worship. Its introduction into the Christian Church is ascribed to Ignatius in the first century after Christ. The Western Church is said to have received it more particularly from St. Ambrose.

Antipodes, ăn-tĭp'ō-dēz (from the Greek *anti*, against, and *pous*, a foot), the name given to inhabitants of the earth diametrically opposite to each other, and of course literally applied to those who turn their feet toward each other; or to any part of the earth's surface situated diametrically opposite any given part. The antipodes live in similar and, except at the equator, opposite latitudes, and their longitudes differ by 180°. Hence the difference in their time is about 12 hours, and their seasons are reversed. The spherical form of the earth naturally leads us to the idea of the antipodes, of whose existence some idea was entertained even before the age of Cicero.

Antipodes Island, ăn-tĭp'ō-dēz is'land, a small uninhabited island in the South Pacific Ocean, about 460 miles southeast-by-east of New Zealand; so called from being nearly antipodal to Greenwich, England. Its area is about 11 square miles.

An'tipope, a pontiff elected in opposition to one canonically chosen. The first antipopes were: Felix, during the pontificate of Liberius (352–366) and recognized during the absence of Liberius; Ursinus, against Damasus (366–384); Eulalius, against Boniface I. (418–422); Laurentius, against Symmachus (498–514); Dioscurus, against Boniface II. (530–532); Vigilius, against Sylverius, until 540, then canonical; Constantine, against Paul (767); Anastasius, against Benedict III. (855); John XVI., Philogathus, against Gregory V. (996–999); Gregory, against Benedict VIII. (1012–24). During the Middle Ages several emperors of Germany set up Popes against those whom the Romans had elected without consulting them. Otho the Great displaced successively two Bishops of Rome; and when the rival Pope, Sylvester III., had expelled the simoniacal and profligate Benedict IX. (1033–45), the latter was brought back by the German king, and soon afterward relinquished his dignity in consideration of a large tribute. Gratianus, who had persuaded him to yield, was now named Pope by the Romans as Gregory VI. There were, consequently, three Popes, but their claims were all set aside at a council convened at Sutri by the emperor, Henry III., and a new Pope elected as Clement II. in 1046. Shortly after, Pope Alexander II. found a rival in Honorius II., the nominee of the emperor; but his claim was ratified by a council convened at Mantua. In 1080 the same unseemly spectacle was witnessed, when the emperor Henry IV. elevated to the papal chair Guibert of Ravenna, under the title of Clement III., in opposition to his own implacable adversary, Gregory VII. After the death of Gregory (1085), Clement was antipope successively to Victor III. (1087–88) and Urban II. (1088–99). Other antipopes at this period were Albert, Theodoric, Maginulf, all in one year (1100–01); Maurice Burdin, against Gelasius II. (1118–19) and Calixtus II. (1124–30) Innocent II. (1130–43) triumphed over the antipope Anacletus II. by the help of St. Bernard; and Alexander III., during his pontificate (1159–81), had to contend with three successive antipopes, the election of only one of whom, however, Victor IV., in 1159, has any appearance of canonical validity. The others were named Pascal III. (1168) and Calixtus III., the same year. After a long contest Clement V. was elected in 1305, and four years later transferred his seat to Avignon, where his successors reigned for nearly 70 years, losing the while, by their subjection to French influences, the sympathies of Germany and England. Nicholas V. (1328–30) was antipope against John XXII. The election of Urban VI. in 1378 occasioned "the great schism of the West," which divided the Church for 50 years. He was elected by the Romans, who demanded an Italian Pope after the death of Gregory XI. The French cardinals, then a majority in the curia, on the plea that they had elected the Pope only under intimidation, withdrew to Provence, and elected an antipope under the name of Clement VII., who was recognized by France, Spain, Savoy, and Scotland; while Italy, Germany, England, and the whole North of Europe supported Urban VI. For 38 years Christian Europe was scandalized by the spectacle of two Popes, one at Geneva, another at Rome, in turn hurling the most awful anathemas of the Church at each other. At the beginning of the 15th century an attempt was made to prevail on both the rivals, Gregory XII. at Rome, and Benedict XIII. at Avignon, to renounce their claims with a view to promote union, but both evaded this as long as possible. At length, however, the cardinals attached to either court agreed to summon a general council, which met accordingly at Pisa in 1409. The council deposed both Popes and constituted the separate bodies of cardinals into one conclave which elected Alexander V. to the papal chair. The schism was finally healed when the council of Constance deposed John XXIII., and Gregory XII. and Benedict XIII. agreed to abdicate and recognize as Pope Martin V., against whom Peter de Luna and Munoz of Barcelona were antipopes. The council of Basel (1431–47), in its struggle with Pope Eugenius IV. (1431–47) for supremacy, attempted to arrogate to itself the papal functions and proceeded to elect Amadeus of Savoy Pope as Felix V. The attempt, however, failed; the Popes Eugenius IV. and Nicholas V. (1447–1455) secured their authority, the ambitious council finally dissolved itself, and Felix V. resigned his empty dignity, and was raised to the rank of cardinal by the magnanimous Pope himself. This was the last occasion on which the faithful were distracted by the sight of a rival pontiff within Christendom.

An'tipyret'ics, the name given to remedies employed to reduce temperature in diseased conditions. Direct application of cold in the form of baths, packs, ice-cloths, etc., are the most valuable and efficient antipyretics. In some definite affections, notably in malaria, quinine, by

destroying the parasite that causes the disease, reduces the temperature. Of late years a large number of synthetic drugs have been introduced to be used for the purpose of reducing temperature in disease. These are more technically the antipyretics. The field of their usefulness in this particular function, however, is constantly narrowing, since it is being recognized that fever is only a symptom and often not a dangerous one at that. Rational therapeutics would first eliminate the cause of fever, and drugs are then rarely necessary. The more important drug antipyretics are antipyrin, opium, quinine and its allies, salicylic acid and its compounds, alcohol, chloral, squills, phenacetin, and others of the modern analgesics (q.v.). The most important of the functions of most of these drugs is their power to relieve pain. Their antipyretic action is often extremely complex — in general they diminish oxidation, increase perspiration, or diminish the force and frequency of the heart-muscle contractions. See ANALGESICS; ANIMAL HEAT; FEVER.

An'tipy'rin, the trade name of an artificial alkaloidal substance known to the chemist as oxydimethyl-quinizin, or, more accurately, as oxy-phenyl-di-methyl-pyrazole. It is a crystalline substance melting at 235° F. and soluble in water, alcohol, and ether. Antipyrin is a derivative of coal-tar, an organic nitrogenous basic compound (synthetic alkaloid?) with the composition $C_6H_5(CH_3)_2C_3HN_2O$. It forms colorless scaly crystals devoid of odor and with a slightly bitter taste. It is soluble in water, alcohol, and chloroform. It is one of the first of the modern army of synthetic drugs, and is still one of the most valuable, though not so extensively lauded as formerly, the patent on its exclusive production by one manufacturer having expired in 1899. Its action locally is somewhat antiseptic, and solutions applied to mucous membranes render them slightly anæsthetic and contract the blood-vessels. It therefore makes a good local application to catarrhal membranes. Taken internally it is readily absorbed, reduces the force and frequency of the heart action, causes a dilatation of the blood-vessels of the periphery of the body, thus bringing about sweating and increased heat elimination (see ANIMAL HEAT). Its chief antipyretic action is due to the co-ordinating mechanism which lowers the heat at the point where the temperature is maintained and accumulated (the skin); the dilatation of the capillaries brings about the dissipation of this accumulation, which vascular dilatation is caused by the action of the heat-regulating mechanism possibly situated at the base of the cerebrum. Antipyrin is also an efficient and valuable analgesic, particularly serviceable in headache, neuralgias, in dysmenorrhea, in rheumatism, and in affections of the peripheral nerves and joints generally. By its pain-relieving qualities it makes a valuable adjunct in hypnotic mixtures. It is also a good antispasmodic (q.v.).

Antipyrin is mainly eliminated by the kidneys. It may cause symptoms of poisoning. These are collapse, cold extremities, and some degree of cyanosis and heart weakness. It is not one of the anilin (q.v.), analgesic antipyretics and hence has not the characteristic blood-poisoning properties of the anilins (acetanilid, exalgen, methacetin, and similar bodies). It also produces a number of untoward symptoms, notably skin eruptions, cramps of the intestine and of the bladder. It also may cause disturbances of sensation in the extremities. Doses of from 10 to 15 grains have caused serious symptoms of poisoning, particularly in children. See ANALGESICS; ANTIPYRETICS.

An'tiquaries, persons devoted to the study or collection of antiquities. In most of the countries of Europe and America there are important associations of antiquaries. The object of these societies is the collection and preservation of ancient manuscripts, inscriptions, coins, sculptures, etc.; the examination of ancient edifices and other remains; in short, the investigation of everything likely to throw light on the manners, customs, and history of the past. The chief antiquarian society of Great Britain is the Society of Antiquaries of London, founded in 1572, revived in 1707, and incorporated in 1751. The president for the time being is an official trustee of the British Museum. It has published 'Archæologia' (1770, etc.), 'Vetusta Monumenta' (1747), and 'Proceedings' from 1849. The Society of Antiquaries of Scotland was founded in 1780 and incorporated in 1783. The Archæological Institute of Great Britain and Ireland, established in 1843, is a society of similar character. The American Antiquarian Society (q.v.) was organized in 1812.

An'tiquary, The, a romance by Sir Walter Scott (1816). It is weak in its supernatural machinery, but strong in dialogue and humor. The plot centres about the fortunes and misfortunes of the Wardour and Glenallan families, and the chief character is Mr. Jonathan Oldbuck, the Antiquary, whose odd sayings and garrulous knowledge are inimitably reported.

Antiques', a term specifically applied to remains of ancient art, such as statues, paintings, vases, cameos, and the like, and more especially to works of Grecian and Roman antiquity.

Antiq'uities of the Jews, The, a famous work by the historian Flavius Josephus, concluded in the 13th year of the reign of Domitian. It was addressed especially to the Greeks and the Gentiles.

Antiq'uity, a term generally denoting the time prior to the irruption of the barbarians into the Roman empire in the middle of the 5th century, or previous to our era. In a narrower sense it is applied to the period over which the ancient history of the two principal nations of former times, the Greeks and Romans, extends. The name antiquities is commonly given to the remains of ancient art and industry, such as tools, weapons, sculptures, inscriptions, etc. It is also used in a wider sense to signify anything appertaining to a knowledge of the politics, manners, religion, literature, and arts of the nations of antiquity, or of the modern nations, until the existing order of things commenced. See ARCHÆOLOGY.

Anti-Rent Agitation, in New York State. Although the manorial system of large landed estates with leasehold tenants disappeared early in all other parts of the northern States of the Union, it flourished vigorously along the Hudson and Mohawk until well into the 19th century. This was due probably to the high per-

sonal qualities and tenacious landlordship of the Van Rensselaer (q.v.) and Livingston (q.v.) families, and the desire they inspired in others to become semi-feudal country gentlemen of the same stamp. The greatest of these holdings was the Van Rensselaer patroonship, called Rensselaerswick, derived from a Dutch grant confirmed by James II.; originally comprising the entire counties of Albany, Rensselaer, and Columbia,— 20 miles on each side of the Hudson,— and to the last retaining many hundreds of large farms in them. Almost as large was the "Livingston Manor," at one time holding 162,000 acres in Dutchess and Columbia counties. The extensive Hardenburgh Patent, dating from 1749, occupied large sections in Greene and Delaware counties; and there were many other considerable estates. The tendency in the vicinity of these great manors was not to sell farms, but lease them with feudal incidents, in imitation of their great neighbors; so that in eight or ten of the east-central counties a large part of the land was in tenant farms, mingled with and surrounded by properties in fee. There were some very annoying provisions in some leases; one for giving the landlord a quarter of the proceeds of the sales of produce in case of alienation of the fee, making the landlord a partner with a one-fourth interest. In practice this provision was either not enforced or was commuted for a fraction of the value, and in the Hardenburgh Patent, where was the fiercest resistance and the most bloodshed, there was no such provision at all; but it served as a common grievance whether present or absent. Also rents were often in kind, fixed or shares, which is always fertile in heartburnings; many, however, had been commuted to money. But the actual grievances were slight, and the tenants were probably better off in income than the owners in fee. In Rensselaerswick the first seven years of a lease were usually rent-free; on the Hardenburgh Patent five years, with the next five at half rent; and arrears and reservations were very laxly enforced, often not at all for years,— which was injudicious charity and produced the crisis, as enforcement of back dues meant being sold out and evicted, and agriculture is the one employment that will not endure that from private owners. The insecurity of the old feudal tenures had been removed by the legislation of 1779 and 1789, which abolished them; and the new leases, though having the same rentals and services, were in fee, so that raising of rent and confiscation of improvemnts were impossible. Further legislative regulation was attempted in 1812 to settle the respective rights of patroons and tenants; but the friction continued, and naturally involved all other land dealings,— contracts, mortgages, etc., having as ill an odor as leases. In 1836 a mob in Chautauqua County destroyed a land office with its records, on a rumor that the mortgages were to be foreclosed; and the same thing was only prevented at Batavia by an armed gathering of the townsmen. The matter was brought to a head by the death of Gen. Stephen Van Rensselaer, the eighth patroon of Rensselaerswick. This fine old gentleman, who commanded at Queenston Heights and founded Rensselaer Polytechnic Institute (q.v.), died early in 1839, leaving over $200,000 of uncollected rents and any number of unenforced quarter-sales, and two heirs to whom he left his estates on the respective sides of the Hudson. These heirs undertook to collect the arrears and enforce the rights left in abeyance; and the tenants formed associations to resist. The first to do so were those in the Helderberg Mountains, west of Albany (whence the disturbance is sometimes called the Helderberg war); but those east of the Hudson in Rensselaer County outdid them by forming a mob in disguise and murdering a man. The counties were in open rebellion, and in December Gov. Wm. H. Seward issued a proclamation against the rioters. The sheriff of Albany County with a posse several hundred strong was stopped by 1,500 armed men: a company of militia was called out, but was forced back by a gathering of nearly 1,000, and at last a body of about 1,000 militia had to be sent to Albany. The executions were finally levied, and on the 12th the soldiers were sent home. On the governor's recommendation the legislature appointed a commission to report on a plan of adjustment; but as the only parties who wished the legal *status quo* changed were the tenants, the landlords considered the concessions to be all on their side and refused to listen to its recommendations. A stubborn resistance practically nullified the collection of rents year after year. At length in 1844 the rebellion broke out with tenfold violence, in a general organization through Rensselaer, Schenectady, Columbia, Otsego, Delaware, Ulster, Greene, Dutchess, and other counties, against the payment of any rent whatever, and to compel the lords of the manor to sell their lands to the persons occupying them as tenants. The justifications legal and equitable may be surmised: that the landlords had no title, that the rent had been waived, that the payment of rent was against republican insitutions, etc. A regular agrarian war was instituted: the tenants, plus all the rabble who liked to commit outrage on any side, disguised themselves as Indians in defiance of laws against it, and began a reign of terror, flogging, tarring and feathering, boycotting, and generally ill-using all who took leases, dealt with landlords, or obstructed obstruction in any way. One laborer who had bought lumber from a leased farm and was taking it to market was shot dead by a mob in a struggle to take it from him. At length, on 7 Aug. 1845, a deputy sheriff of Delaware County was fatally shot by such a mob while serving a process; the extortion which called for this bloodshed was two years' back rent at $32 a year. These performances went on for months; Gov. Silas Wright, who in his message of 1845 had favored commutation of rents and ownership in fee though calling for sharp laws to punish outrages, now summoned a military force and sternly put down the rebellion. More than 50 convictions were obtained, two of murder with sentence of death, which the governor commuted to imprisonment for life; but in his next year's message (1846) he recommended the abolition of distress for rent and the limitation of leases to five or ten years. The constitutional convention of 1846 abolished feudal tenures and limited leases to twelve years. This was not at all what the Anti-Renters wanted, however, but abolition of rent altogether and proclamation of the lease-holders as owners. Their cause had been an

issue in State politics for years, fomented by agitators and newspapers; and the Whigs, seeing that they controlled the legislative delegations of eleven counties, nominated for governor in 1846 their chief legislative champion, John Young, against Silas Wright, elected him by their aid, and he promptly pardoned all those who had been sentenced, pronouncing their offenses "political." He also recommended State suits against landlords to try titles. The Anti-Renters had "adopted" a part of the State ticket and not the rest, to show their strength, and polled about 5,000 votes; the next election (of 1848) they did the same: and the legislature, alive to the value of this body of votes, directed the attorney-general to bring a test suit against Harmon Livingston. The decision in November 1850 was for Livingston; but the nearly twelve-years struggle and ruin of property values had wearied the landlords, and the decent tenants were perhaps ashamed of their breach of contract. The former offered to sell the farms, and the latter were willing to buy; and the great patroonship and patents were rapidly broken up. Meantime there was a mass of private litigation, and several cases went up to the Court of Appeals; which in October 1852 declared that without reference to the Constitution of 1846, agreements in restraint of alienation of titles in fee, and therefore reservations of quarter-sales, were void. As this left the landlords no right which could oppress the tenants, and the latter nothing to oppose except a payment of honest debts, the Anti-Rent agitation passed out of sight as a dignified political entity. But the spirit was not quite dead. As late as July 1866 an anti-rent riot broke out in Knox, Albany County, which had to be suppressed by the militia. The next month a landowner's agent in Berne was fired at and his horses were shot. These, however, were belated estrays: for a generation land contracts have been on a footing with all others. Consult Jay Gould, 'History of Delaware County' (1856); Roberts, 'History of New York' (1887); Cheyney, 'Anti-Rent Agitation' (1887).

An'tirrhi'num, the designation of a genus of annual or perennial plants of the natural order *Scrophulariaceæ,* commonly known as snapdragon, on account of the peculiarity of the blossoms, which resemble a face or a mask. They all produce showy flowers and are much cultivated in gardens. Many varieties of some of them, such as the great or common snapdragon (*A. majus*), have been produced by gardeners. The plant is not native in America, such specimens as are seen growing wild having escaped from gardens.

Antisana, än'te-sä'na, a volcano in the Andes of Ecuador, 35 miles southeast-by-east of Quito. Whymper, who ascended it in 1880, makes its height 19,260 feet.

An'tisci'an (Greek *anti,* over against; *skia,* a shadow), a name applied to those who live under the same meridian, at the same distance north and south of the equator, and whose shadows at noon consequently are thrown in contrary directions.

An'tiscorbu'tics. See SCURVY.

An'ti-Sem'itism, a name applied to a movement against Jews as such, the modern opponents of the Jews in Russia, France, and Germany. It is founded on race hatred and arises from social, economic, and political causes. In Berlin an Anti-Semitic League was formed in 1879 to restrict the liberty of Jews in Germany. Since then similar organizations have been formed in Russia, Austria, Greece, and Holland. The movement in Russia assumed a more brutal character than in Germany, and thousands of Jews fled to the United States, Spain, and elsewhere. In Hungary violent anti-Jewish riots occurred at Pesth, Zala, and elsewhere, which were not brought to an end until martial law was proclaimed. The second trial of Capt. Albert Dreyfus, in 1899, aroused an intense anti-Semitic feeling in France. See JEWS AND JUDAISM.

An'tisep'tic, a term denoting that which arrests decay. The development of the knowledge that organic bodies are broken down or decayed by minute plants, fungi, bacteria, etc., led to the idea of preventing the action of these bodies by the employment of some appropriate substances. In medicine it had been found that many of these bacteria produced a condition known as *sepsis,* or poisoning, and when Lister first used the carbolic spray to prevent the development of these bacteria the word *antiseptic* came into use. Used originally to apply to septic organisms it has come to be applied to any substance that would inhibit the growth or destroy these agents of putrefaction or of disease. A *germicide* is any agent that kills these low forms of plant life; *fungicides* are used on the large fungi; *bactericides* on the bacteria. The word *disinfectant* should properly apply to a substance used for the destruction of a definite infecting agent, such as phthisical sputum, or typhoid urine or stools, but it too often is employed for some remedy that destroys a disagreeable odor — a *deodorant.* Thus most so-called disinfectants, manufactured to place in closets or urinals, are really nothing but foul-smelling deodorants. As disinfectants they are delusions and snares. Germicides, bactericides, antisepticides, may be divided into two groups, physical and chemical. In the former group is heat, the most important of all germicides. Burning is the best means for the disinfection of the non-valuable surroundings of patients who have had any severe contagious disease such as diphtheria, typhoid fever, plague, scarlet fever, etc. It is the best agent for the destruction of all tuberculous sputum. Boiling is another efficient means of disinfecting, or sterilizing. The boiling of water or milk suspected to contain the bacteria of typhoid or diphtheria is efficient. Boiling all bed linen in contact with contagious diseases is advisable.

The boiling of preserves and then hermetically sealing the cans to prevent the entrance of molds is practised by all housewives. When the fruit "ferments," it has either not been boiled long enough, the cans were not thoroughly cleansed by boiling water, the rubbers and tops not sterilized, or a hole has been left whereby the spores of molds have entered. Cold is a preservative only: it prevents the multiplication of these low forms of plant life, but does not destroy them.

Chemical antiseptics have been in vogue ever since the work of Tyndall, Pasteur, Koch, and Lister showed the role of lower plant forms in the causation of putrefaction and sepsis. In the arts many antiseptics are used to preserve foods. The smoking of hams, etc., is the old empirical method, antedating modern means probably by hundreds of years, the smoke containing creosote and bodies related to carbolic acid. Boracic acid, alum, salicylic acid, formalin, nitre, common salt, sugar, etc., are all extensively used as food preservatives. Wood is protected from rotting by the injection of creosote, tar, and related fungicides. In modern antiseptic surgery it is not the destruction of bacteria, but rather their prevention, that is desired, and *asepsis* is the modern method, not *antisepsis.* By thorough sterilization of everything that comes in contact with a patient's body the modern surgeon prevents infection by keeping bacteria out. Should the nature of a wound be such that it is already infected, then antiseptics are of service. The most valuable surgical antiseptics are the phenols and their derivatives (carbolic acid, salicylates, etc.), salts of mercury, silver, lead, aluminum, copper, and zinc, preparations of chlorin, iodin, bromin, organic aldehydes, formaldehyde, benzaldehyde, and the oxygen-producing compounds, hydrogen peroxide and other peroxides. For the comparative strength of the antiseptics see under their respective heads. Also Sternberg, 'Bacteriology'; Flügge, 'Die Mikroorganismen.' See BACTERIA; FUNGI; INFECTION; KOCH; PASTEUR; PUTREFACTION; SPONTANEOUS GENERATION.

Anti-Slavery Society, the American, was organized in Philadelphia, Dec. 1833, by delegates from similar local and state societies. The first of these societies was formed in Boston in Jan. 1832, by William Lloyd Garrison and others. The American society took a radical stand for the abolition of slavery. A difference of opinion among the members caused a split in the society in 1840, and eventually both factions joined the Liberty Party (q.v.). A small coterie of the original society continued to exist however until the adoption of the 15th Amendment in 1870. See LIBERAL PARTY; SLAVERY.

An'tispasmod'ic, a medicine proper for the cure of spasms and convulsions. Opium, balsam of Peru, and the essential oils of many vegetables are the most useful of this class of medicines.

Antis'thenes of Athens, a Greek philosopher who founded the sect of Cynic philosophers; b. in Athens 444 B.C. He was a disciple of Socrates, and is said to have aided in bringing some of his persecutors to justice. He taught at the Cynosarges, a gymnasium appropriated to Athenians who had foreign mothers. His philosophy was a one-sided development of the Socratic method. According to his teaching virtue should render man independent of the ordinary events of life. He himself lived in a very austere, self-denying fashion.

Antis'trophe, (Gr. *anti*+*strophē*, from *strephō*, I turn), the name of one of the divisions of a Greek choral ode, corresponding to the *strōphē* and following it. The singing of the strophes on the stage was accompanied with a motion or turn from right to left.

An'titox'ins, the name given to peculiar bodies developed in the human body or in the body of an animal, supposed to be antagonistic to the poisons, or toxins, of disease. These antitoxins are specific for definite diseases and constitute one of the protective agents in the body's battle with disease. For the full consideration of these and other similar bodies see IMMUNITY.

An'ti-trade, a name given to any of the upper tropical winds which move northward or southward in the same manner as the trade-winds which blow beneath them in the opposite direction. These great aërial currents, descending to the surface after having passed the limits of the trade-winds, form the southwest or west-southwest winds of the north temperate, and the northwest or west-northwest winds of the south temperate zones.

An'titrin'ita'rian, a name applied to one who does not receive the doctrine of the divine Trinity as it is represented by the Nicene and Athanasian creeds, and either puts the Son and the Holy Spirit in the Godhead below the Father, or considers Christ as merely a man, and the Holy Spirit an arbitrary personification of the divine mind. Antitrinitarians of the latter class are Unitarians (q.v.), while those of the former class are relatively Trinitarians.

Anti-Trust Laws, in the United States. (See also TRUSTS.) The first of these on the statute books was an ordinance of Alabama in 1883 against the pooling of freights by railroads. The first general law against business combinations was enacted by Kansas in 1889. But the general movement against trusts which took shape in legislation was in 1889, when five States and Territories passed laws to render combinations in restraint of trade illegal and punishable, and two more (Washington and North Dakota) incorporated similar provisions into the constitutions with which they were admitted to the Union. In the first half of 1890 three more States joined the movement with legislation; and on 2 July the Federal Congress enacted the "Sherman Law" against trusts. Since then over as many more States and Territories, toward 30 in all, have placed like statutes on their books. The provisions are substantially alike in all, making the persons engaged in such combinations liable to fine and imprisonment, and the corporations or firms punishable by loss of charter or of right to carry on business within the State where the offense is committed. The decisions of the circuit courts at first were so narrowed as practically to nullify the provisions of the laws; it being held that the combinations, as at common law, must be proved inequitable and injurious to the public, and calculated not merely to abate competition, but absolutely to monopolize the business for the purpose of extortion. But these decisions were reversed by the United States supreme court, which held that the laws made no distinction between partial and complete monopoly, or equitable and inequitable. It had been claimed also that the laws were unconstitutional, as violating the Fifth and Fourteenth Amendments, that no person shall be deprived of liberty without due process of law, and that the liberty of making contracts is an essential portion of this: but the supreme court interprets them to mean legal contracts, and

that under its power to regulate commerce Congress can decide what contracts are legal; while the State courts hold that such regulation is competent to the States under their police power.

The Sherman Act is as follows:

1. Every contract, combination in the form of trust or otherwise, or conspiracy, in restraint of trade or commerce among the several States, or with foreign nations is hereby declared to be illegal. Every person who shall make any such contract or engage in any such combination or conspiracy shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by a fine not exceeding $5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

2. Every person who shall monopolize, or attempt to monopolize, or combine or conspire with any other person or persons to monopolize any part of the trade or commerce among the several States, or with foreign nations, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be punished by fine not exceeding $5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

3. Every contract, combination in the form of trust or otherwise, or conspiracy in restraint of trade or commerce in any Territory of the United States or of the District of Columbia, or in restraint of trade or commerce between any such Territory and another, or between any such Territory or Territories and any State or States or the District of Columbia, or with foreign nations, or between the District of Columbia and any State or States or foreign nations, is hereby declared illegal. Every person who shall make any such contract or engage in any such combination or conspiracy shall be deemed guilty of a misdemeanor, and, on conviction thereof, shall be punished by fine not exceeding $5,000, or by imprisonment not exceeding one year, or by both said punishments, in the discretion of the court.

4. The several circuit courts of the United States are hereby invested with jurisdiction to prevent and restrain violations of this act, and it shall be the duty of the several district attorneys of the United States in their respective districts, under the direction of the attorney-general, to institute proceedings in equity to prevent and restrain such violations. Such proceedings may be by way of petition setting forth the case and praying that such violation shall be enjoined or otherwise prohibited. When the parties complained of shall have been duly notified of such petition the court shall proceed, as soon as may be, to the hearing and determination of the case; and pending such petition, and before final decree, the court may at any time make such temporary restraining order or prohibition as shall be deemed just in the premises.

5. Whenever it shall appear to the court before which any proceedings under section four of this act may be pending, that the ends of justice require that other parties should be brought before the court, the court may cause them to be summoned, whether they reside in the district in which the court is held or not; and subpœnas to that end may be served in any district by the marshal thereof.

6. Any property owned under any contract or by any combination, or purchased to any conspiracy (and being the subject thereof) mentioned in section one of this act, and being in the course of transportation from one State to another, or to a foreign country, shall be forfeited to the United States, and may be seized and condemned by like proceedings as those provided by law for the forfeiture, seizure, and condemnation of property imported into the United States contrary to law.

7. Any person who shall be injured in his business or property by any person or corporation by reason of anything forbidden or declared to be unlawful by this act, may sue therefor in any circuit court of the United States in the district in which the defendant resides or is found, without respect to the amount in conspiracy, and shall recover threefold the damages by him sustained, and the cost of suit, including a reasonable attorney's fee.

8. That the word «person» or «persons,» wherever used in this act, shall be deemed to include corporations and associations existing under or authorized by the laws of either the United States, the laws of any of the Territories, the laws of any State, or the laws of any foreign country.

An'titype, a word denoting a type or figure corresponding to some other type. It is in the sense of copy or likeness that the word occurs in the New Testament (Heb. ix. 24; i Peter iii. 21). By the fathers of the Greek Church antitype is employed as a designation of the bread and wine in the sacrament of the Lord's supper.

Antium, ăn'shĭ-ŭm, one of the most ancient and powerful cities of Latium, the chief city of the Volsci. It was situated on a promontory, and was a flourishing seaport. It was taken by the Romans in 468 B.C., but soon revolted, and maintained its independence till finally taken by Rome in 338 B.C., and after this it appears as one of the maritime colonies of Rome. Toward the close of the republic and during the empire it was a favorite residence of the wealthy Romans, and both the town and its neighborhood were adorned with temples and splendid villas. Nero and Caligula were born at Antium. It was entirely destroyed by the Saracens; but vestiges of it still remain at Porto d'Anzo, its modern successor, near which many works of art, including the Apollo Belvidere and the Borghese Gladiator, have been found.

Ant'lers, the weapons borne upon the head of a male deer during the breeding season. They are an outgrowth of true bone supported upon protuberances from the crown of the skull, called pedicels. As the spring approaches, the hairy skin with which these are covered becomes highly vascular and swollen with blood and serum carrying lime salts. This grows outward and gradually assumes the form of the antler, characteristic of the species, which for a time is in a soft and vascular state, and covered with what hunters call «velvet.» There is continually deposited within this growth the substance of bone, which fills and solidifies the structure from the centre outward, until in the course of four or five months all has become solid, the outer skin shrinks and dries and

presently falls or is rubbed off. These antlers remain firm upon the head and useful as weapons until the middle of the following winter, when they become loosened and fall off. The process is repeated the following spring, and the antlers are thus lost and replaced annually as long as the stag lives. In the deer, with the single exception of the reindeer, antlers are worn only by the males and are a secondary sexual character. That they are associated with the reproductive function, says Beddard, is shown by their being shed after the period of rut; and also by the stunting effect upon the horns which any injury to the reproductive glands produces. Various degrees of degeneration are to be seen in the antlers of captive deer resulting from varying degrees and periods of gelding.

The sport of stag-hunting has preserved a set of ancient terms, mostly of French origin in the Middle Ages, designating the different parts of the antler and the successive stages of growth, and these have come to stand for a deer of a certain age or condition. They were all derived from and particularly applicable to the European red deer (*Cervus elephas*), which more than any other species is preserved for hunting in Europe. This nomenclature is summarized as follows in 'Cassell's Natural History,' Vol. III.—"In the common red deer, in the spring of the year following its birth, the antlers are nothing more than straight, conical, and unbranched 'beams,' the animal being then known as a 'brooket.' In the following spring the antler has, besides the 'beam,' a small branch from its base, directed forward, known as the 'brow antler'; it is then termed 'spayad.' In the third year an extra front branch is formed, known as the 'tres,' and the whole antler is larger. The tres is sometimes seen in the smaller antler of the spayad. In the fourth year the brow antler is doubled to form the 'brow' and the 'bez-tine,' at the same time that the top of the main beam divides into the 'sur-royals' of the 'staggard,' or four-year-old male. In the fifth year the sur-royals become more numerous, the whole antler of the 'stag' being heavier than previously, only to be exceeded in weight by those of the fully adult 'great hart' with ten or more 'points,' each being larger and longer than the year before." A deer of 12 points is known in Scotland as a "royal stag," but although sometimes antlers have more than 12 points, no recent antlers quite equal those which have been preserved from old times before all the best deer were so systematically shot each year. Where the number of points is exceedingly large, as it is in some curious specimens whch show fifty or seventy-five, they are no longer a record of the years of the animal's life, but of injuries to the horns, causing unnatural branchings. The horn of antlers is of commercial value, being much used for the handles of knives and similar articles.

Ant'lia, or **Antlia Pneumatica,** the name of one of the 14 southern constellations placed in the heavens by Lacaille in connection with his work at the Cape of Good Hope in 1751–2. It is situated between Vela, Pyxis, Hydra, and [illegible].

Ant'-li'on, a term applied to the larva of *Myrmeleon*, a neuropterous insect of the family *Myrmeleonidæ*. It is a singular-looking creature, the body somewhat broad and flattened behind, the head provided with enormous jaws which have a groove beneath, in which the maxillæ slide back and forth. It can thus pierce the bodies of small soft-bodied insects, flies, etc., and suck their blood without moving the jaws on which the victim is impaled. It makes a pit in fine sand, at the bottom of which it lies with its body buried and its jaws wide open, ready to seize any luckless insect which may fall in. When an insect comes near the edge of the pit, the ant-lion, by a toss of its head, hurls at it a shower of sand, which knocks it down, so that it slides into the pit and is seized. Ant-lions are known in confinement to spend the winter in the larval state if fed with flies, caterpillars, and spiders. In the spring the larva spins a rather large, round, silken cocoon covered with grains of sand, within which it changes to a pupa, and the winged insect emerges early in June. The imago has long gauzy wings, both pairs alike, and is rarely seen in the northern and eastern States. The conical, crater-like pits of the ant-lion may be seen in sheltered places in loose sand to the number of from 50 to 75. It occurs from Maine to Florida.

Antofagasta, än'tō-fa-gäs'ta, a province in northern Chile, extending the whole width of the country and covering an area of 60,968 square miles. It was ceded by Bolivia to Chile in 1884. Much of its territory lies in the rocky desert of Atasama, a feature which makes it generally unsuitable for agriculture. It is, however, one of the richest sections of the world in the ores of precious metals. Pop. 50,000. Antofagasta, its capital and principal seaport, is the terminus of a railroad that extends to the rich mining sections in the northeast. It also ships much ore, nitrate of soda, and bullion, and contains silver-smelting works. Pop. (1901) 19,482.

Antommarchi, än'tōm-mär'ke, **Carlo Francesco,** an Italian physician: b. in Corsica in 1780; d. in St. Antonio, Cuba, 3 April 1838. He was professor of anatomy at Florence when he offered himself as physician of Napoleon at St. Helena. Napoleon at first received him with reserve, but soon admitted him to his confidence, and testified his satisfaction with him by leaving him a legacy of 100,000 francs. On his return to Europe he published the 'Derniers Moments de Napoléon' (1823). He also wrote the text for a folio series of anatomical plates published in 1823–6, and in 1830 exhibited what he asserted to be a death mask of Napoleon. In 1836 he went to New Orleans, where he practised homœopathy.

Antonelli, ä'tō-nĕl'le, **Giacomo, Cardinal,** an Italian ecclesiastic: b. 1806; d. 1876. He was educated at the Grand Seminary of Rome, where he attracted the attention of Pope Gregory XVI., who appointed him to several important offices, and on the accession of Pius IX., in 1846, Antonelli was raised to the dignity of cardinal-deacon. Two years later he became president and minister of foreign affairs, and in 1850 was appointed secretary of state. During the sitting of the Œcumenical Council (1869–70) he was a prominent champion of

the papal interest. He strongly opposed the assumption of the united Italian crown by Victor Emmanuel.

An'tonine Column, the name given to the sculptured pillar erected by Marcus Aurelius to the memory of his father-in-law, Antoninus Pius. The splendid staircase, with 190 steps hewn in the 19 blocks of marble of which the column is composed — the statue of St. Paul crowning its top — and the bas-reliefs around the column illustrating the victories of Marcus Aurelius over the Marcomans, present an appearance of singular magnificence. The Doric and Corinthian styles are blended in the architecture of the column in a remarkable manner. The pedestal and top are Doric, while the proportions of the column are Corinthian. The bas-reliefs, in imitation of those of the column of Trajan, are in beauty and purity of execution rather inferior to the original. The column was restored to its present condition in the latter part of the 16th century by Domenico Fontana, the architect of Sixtus V., and still stands in the Piazza Colonna as one of the chief ornaments of Rome.

Anto'nius Gaius, a Roman consul, the colleague of Cicero, who defended him when accused of participation in the Catiline conspiracy. He was the son of Marcus Antonius the orator, and an uncle of Mark Antony.

Antonius, Marcus, commonly known as Mark Antony, a Roman triumvir: b. 86 B.C.; d. 30 B.C. He was the grandson of Marcus Antonius, the greatest orator and one of the greatest men of his day. His father, also Marcus Antonius, was surnamed Creticus in derision, from a disgraceful defeat which he suffered in an unprovoked invasion of the isle of Crete. He went abroad early, served with Gabinius in Syria, and distinguished himself greatly, both there and in Egypt, where he already gave tokens of consummate soldiership. He next joined Cæsar in Gaul, where he passed several campaigns with increasing honor as one of his legates, and deserved much of the credit, usually given to his leader, for the total defeat of Vercingetorix at the terrible siege of Alesia. Being elected one of the tribunes of the people, when the senate ordered Cæsar to disband his forces, he, with Quintus Cassius, vetoed the bill; and, on the senate proceeding to arm the consuls with dictatorial power by the vote *ne quid respublica detrimenti capiat,* they fled together, disguised as slaves, to Cæsar's camp, feigning to believe that their lives were in danger, thus giving that ambitious general the deserved occasion for crossing the Rubicon and marching upon Rome. In reward for this service, when Cæsar went to follow up his fortunes by crushing out the Pompeian party in Spain, he left Antony governor of Italy and lieutenant-general of his forces. He astounded all Italy by the ostentation and cynicism of his vices, but when the last struggle took place between Pompey and his own commander, he at once laid aside the debauchee and resumed the soldier. His skill preserved the fleet and intrenchments at Dyrrachium; it was he who commanded the victorious left wing in the crowning conflict at Pharsalia, and turned the wavering tide of success to the standards of Cæsar. When the Ides of March had come, and great Cæsar fell at the base of Pompey's statue, it was the masculine and sonorous eloquence of Antony — for he was an orator second to Cicero and Cæsar only — that did actually raise the stones of Rome to mutiny and forced the discomfited murderers to fly from their half-finished task. It was Antony's soldiership and Antony's sword that defeated Cassius and drove Brutus to suicide, while the cold, cowardly, crafty Octavius was sleeping in his secure tent. In the proscriptions which followed it is characteristic of Antony that he was by so much the more insolent, as he was the less cruel, of the triumvirs. But the third triumvir, the imbecile Lepidus, was soon disposed of, and Octavius and Antony divided the Roman world, as masters. Antony took the East; Octavius, the cold formalist, betook himself to the West. Thenceforth the life of Antony was one wild dream. Once he broke from his luxurious lethargy, invaded central Armenia and penetrated Parthia; and then, forced to retreat at length by the circumstances of the country, the climate, the innumerable hordes of Oriental horse, brought off his army by a most extraordinary retreat. In 21 days he fought 18 pitched battles, marched 300 miles, through one continuous skirmish, and when he reached the boundary stream his Parthian pursuers unstrung their bows and bade him go his way unharmed. He returned to his life of luxury and to Cleopatra, but his career was run. Rome took arms against him; his troops, his mistress, his fortune deserted him; and Actium saw him, for the first time, with his back to his foes. Deceived to the last by the Egyptian queen, who imposed upon him by a false rumor of her death, he died by his own hand. Most like he was to Mirabeau in that he was everything at times, and everything almost the greatest, but nothing long — orator, soldier, statesman; trifler, buffoon; tribune, triumvir, conqueror; faithful lover, false husband, frantic debauchee; and, when the wine of life was quaffed to the lees, a fearless suicide at last.

Antonius, Marcus, a famous Roman lawyer surnamed the Orator: b. 143 B.C.; d. 87 B.C. He was prætor in 104, when he fought against the pirates in Cilicia; consul in 99, when he distinguished himself by his resistance to the party of Saturninus; and censor in 97. He was famed for his eloquence in the forum, rendering, according to Cicero, Italy the rival of Greece, and for his integrity in public life. As an aristocrat he adopted the party of Sylla, and was put to death by Marius and Cinna, when they triumphed. He is one of the interlocutors in Cicero's 'De Oratore.'

An'tony and Cle'opa'tra, the second of Shakespeare's Roman plays. In Cleopatra the gorgeous Oriental voluptuousness is embodied in the strong-thewed Antony, the stern soldier-power of Rome weakened by indulgence in lust. The poet follows Plutarch in his narrative. The rulers of the Roman world are Mark Antony, Octavius Cæsar, and their weak tool, Lepidus. While Antony is idling away the days in Alexandria with Cleopatra, in Italy things are all going wrong. At last Antony is shamed home to Rome. Lepidus and other friends patch up a truce between him and Cæsar, which is cemented by the marriage of Antony to Cæsar's sister Octavia. After the great defeat at Actium, Enobarbus and other intimate followers

deserted the waning fortunes of Antony. Being falsely told that Cleopatra is dead, Antony falls on his sword.

Ant Plants. See MYRMECOPHILY.

Antraigues, än'träg, **Emanuel Delaunay, Comte d',** a French politician: b. at Villeneuve de Berg, 1755; d. 22 July 1812. His talents first appeared in his 'Mémoires sur les Etats-généraux' (1788), full of daring assertions of liberty, and one of the first sparks of the fire which afterward rose to such height in the French Revolution. When chosen, in 1789, as a deputy, he defended the privileges of the hereditary aristocracy, ranked himself with those who opposed the union of the three estates, and maintained that the royal veto was an indispensable part of good government. After leaving the Assembly in 1790, he was employed in diplomacy at St. Petersburg and Vienna, where he defended the cause of the Bourbons. In 1803 he was employed under Alexander of Russia in an embassy to Dresden, where he wrote against Bonaparte a brochure entitled 'Fragment du XVIII. Livré de Polybe, trouvé sur le Mont Athos.' He afterward came to England and acquired great influence with Canning. He was murdered, with his wife, at his residence near London, by an Italian servant.

An'trim, a county in northeastern Ireland, bounded on the north by the Atlantic Ocean, east by the North Channel; south by the river Lagau and Lough Neaghand; west by the river Bann. It has an area of about 1,237 square miles, nearly all of which is under cultivation. There are rich beds of iron ore at Glenravel, and extensive mines of fine salt are being worked at Dunerul and Carrickfergus. The chief occupations of the people are the raising of flax, fishing, and the manufacture of linen, cotton, and heavy woolen goods. The capital is Belfast, and other places of note are Larne and Carrickfergus. Pop. (1901) 461,250.

The town of Antrim, situated at the north end of Lough Neagh, on the Six-Mile Water, is not a place of much consequence, though bleaching and malting and the linen and paper manufacture are carried on here. There is a very perfect round tower near it.

Ant'werp (Dutch, *Antwerpen;* French, *Anvers;* Spanish, *Amberes;* Old German, *Antorff;* from "aent werf," "on the wharf"), a province of Belgium, south of Holland, consisting for the most part of an extensive plain of 1,096 square miles, scarcely diversified by a single elevation. It is sandy but fertile, producing grain, flax, hemp, fruit, and tobacco, as well as cattle, sheep, and horses; on the north and northeast, however, there are considerable tracts of morass and heath. The principal rivers, the Scheldt and its tributaries, the Rupel, Nèthe, and Dyle, are navigable; while railways intersect the country in various directions, and there are also several canals. The chief towns are Antwerp, Mechlin (Malines) Turnhout, Lierre, and Boom. Pop. (1901) 819,000.

Ant'werp, the capital of the Belgian province of the same name, situated about 50 miles from the open sea, and 25 miles north of Brussels, in a level tract on the right bank of the Scheldt, which is there about 2,200 feet broad and has a depth at ebb-tide of from 30 to 40 feet, with a rise at spring-tides of 12 or 14. Antwerp was probably founded some time before the 8th century, when the Antwerpians or Ganerbians, as they began to be called, were converted to Christianity. In 837 the town fell into the hands of the Northmen, who kept possession of it for about 60 years. It was erected into a marquisate of the Holy Roman Empire by Henry II. in 1008, and as such was bestowed by Henry IV., in 1076, on Godfrey of Bouillon. About the beginning of the 12th century it had considerable commercial prosperity; and in the 13th its municipal institutions took definite shape. It is worthy of notice that the law of 1290 contained provisions identical with those of the Habeas Corpus Act in England, maintaining the inviolability of the citizen's dwelling, and acknowledging the right of every man to be judged by his peers and to have a voice in the imposition of taxes. As the result of such security and freedom the commerce of the city rapidly increased. English wools for the great manufactories at Louvain, Brussels, Tirlemont, Diest, and Leau, were imported through Antwerp; and English merchants, who formed a "factory" there in 1296, received special protection by charters (1305, 1341, 1346, 1349) from the Dukes of Brabant. Between 1488 and 1570 was the time of the greatest prosperity which Antwerp was destined to attain for several centuries. The discovery of America in 1492, and of the passage to India in 1497, produced a great change in all European navigation, permanently altering the old courses of commerce. While in consequence of this the cities of the Hanseatic League had withered, and Venice, Nuremberg, and Bruges were sinking into decay, Antwerp was rapidly growing wealthy, but in 1576 it was taken by the Spaniards and given up to a three-days pillage. It was vainly besieged by the Duke of Alençon in 1583; and after a very obstinate defense it fell before the assaults of the Duke of Parma, whose triumphal entry took place 17 Aug. 1585. Its glory departed; its commerce was ruined; its inhabitants were scattered. The Dutch in their jealousy endeavored to complete its ruin by building forts on the river to intercept the passage of ships; and finally, by the peace of Westphalia in 1648, the Scheldt was definitely closed. In 1794 the city fell into the hands of the French, who opened the river and made Antwerp the capital of the department of Deux Nèthes. It continued in French possession till 1814. Matters of dispute between Belgium and Holland being settled by the treaty of 1839, Antwerp has continued peacefully to advance in prosperity ever since.

Antwerp is the birthplace of a number of distinguished men in various departments, as the painters Vandyck (b. 1599), Teniers the elder (1582), Teniers the younger (1610), Jordaens (1594), Frans Floris (1520), Gonzales Cocques (1618); the philologist Gruter (1560), the geographer Ortelius (1527), the engraver Edelinck (1649), and, among more modern celebrities, Van Meteren the historian, Ogier the dramatist, and Henri Conscience the novelist. Reubens was born at Cologne, but his family belonged to Antwerp, and he was educated, resided, and died in the latter city.

The cathedral of Notre Dame is its most noteworthy edifice, the largest and most beauti-

ful Gothic structure in the Low Countries. Its area is 70,060 square feet and it contains Rubens' paintings, 'The Descent from the Cross,' 'Elevation of the Cross,' and 'The Assumption.' Other important buildings are the church of St. Jacques, begun in 1491, the Bourse, and the Museum. Pop., exclusive of suburbs (1891) 285,600.

A'orist (Greek, *aoristos,* «indefinite»), the name given to one of the tenses of the Greek verb, expressive of indefinite past time. The Greek verb is very rich in past tenses, possessing besides the aorist the imperfect, perfect, and pluperfect. While these express repetition, continuance, or the relation between one time and another, no such shade of meaning attaches to the aorist. The difference between the first and the second aorist is in form only and not in meaning.

Aor'ta, the name given to the great arterial trunk of the body. It springs from the left ventricle of the heart, arches backward to the vertebral column, and, descending in the back portion of the thorax, passes through the diaphragm into the posterior part of the abdomen, at the lower portion of which, opposite the fourth lumbar segment of the spinal column, it divides into the two common iliac arteries. Throughout its course it becomes smaller and smaller, and gives off a large number of branches, that send blood to all parts of the body. It is not divided into any distinct divisions, but for conventional purposes of description anatomists describe three parts, the arch, the thoracic aorta, and the abdominal aorta. The arch reaches to the lower border of the fifth thoracic vertebra; from this point to the opening in the diaphragm it is known as the thoracic aorta; from the diaphragm to its bifurcation into the iliacs, the abdominal aorta. At its very beginning at the top of the heart it gives off the coronary arteries that supply the walls of the heart with blood. The arch is then conventionally divided into three parts, the ascending, transverse, and descending portions. From the transverse portion of the arch the great vessels of the neck, head, and arms are given off,— the innominate or brachiocephalic artery, that goes to the head and upper extremity of the right side, the left common carotid, to the head on the left side, and the subclavian that supplies the upper extremity of the left side. There are really two large arteries supplying each side, but on the right they arise from the one branch from the aorta, while on the left side the arteries going to the head and to the upper extremities are separate. The thoracic aorta lies close to the spinal column in the chest. It supplies arteries extending to the walls of the chest and to all the viscera in the thorax, lungs, etc., save the heart. The abdominal aorta supplies the diaphragm, the muscles of the walls of the abdomen, the liver, kidneys, spleen, stomach, pancreas, suprarenals, the small and large intestines, the spermatic vesicles, and a part of the pelvis. The two great branches into which it finally divides supply the pelvic walls, the organs in the pelvis, the external genitals, and finally the lower limbs. There are a number of variations in the details of the distribution of the different large vessels of the aorta, but these concern the anatomist. The walls of the aorta resemble in their microscopical structure those of the arteries of the body save in possessing more elastic fibrous tissues. This is necessitated because of the greater pressure on this part of the circulatory apparatus. See ARTERY; CIRCULATION; HEART.

Aosta, ä-ōs'ta, a town of Italy, in Piedmont, 50 miles northwest of Turin. It is the seat of a bishop, and possesses a collegiate and three parish churches, two colleges, and two hospitals. Among its antiquities are a triumphal arch, erected to the memory of Augustus, who rebuilt the town and gave it the name of Augusta Prætoria; a gate with three arches, and the remains of an amphitheatre, and the old Roman walls which still surround the town. It has some trade in wine, cheese, hemp, and leather. Pop. (1901) 7,875.

Aoudad, ä'oo-dăd, or **Arui,** a somewhat goat-like wild sheep (*Ovis tragelaphus*), inhabiting the Atlas Mountains of northern Africa. It is about three feet in height, and its horns, which resemble those of the bharal (q.v.), are about two feet long. It is especially characterized by the long whitish hair depending from the throat, chest, and forelegs, but elsewhere its coat is short and light brown, enabling it to hide easily among the rocks of its mountain home. Many other names are given to it, as «ruffed moufflon,» «bearded argali,» «kebsh» (Egypt), «tidal» or «teybal,» and «beden» (Nubia). It is a common resident in menageries, where it breeds readily.

A'oul, the finest of the Somaliland gazelles (*Gazella sœmmerringi*), with massive lyrate horns. Its height is about 30 inches, and the borders of the ears and face are strikingly marked with black.

Apache, a-pä'chē (Pima, «enemy»), the name of a large Indian tribe of the Athapascan stock, kindred to the Navajos, and originally occupying the region from central Texas to the Colorado River in Arizona. The Spaniards applied the name, borrowed from the Pimas, to all the races just north of Mexico, whom they classed as Apachés de Xila, Apachés de Navajo, and Apachés Vaqueros, the first-named being our Apaches. When the United States by the Gadsden Purchase (q.v.) first came in contact with them they numbered about 10,000 and had long been at mortal feud with the Mexicans. For a few years they gave the Americans relatively little trouble of an acute kind, but after a serious raid in 1857 it was urged by those with knowledge that they should be settled north of the Gila, taught industries, and watched. This was not done, however, and in 1860 the whole tribe went on the warpath. The next year the Civil War caused the troops to be withdrawn, and in a short time the Apaches had murdered or driven out every white inhabitant of the Arizona Territory except a few hundred who took refuge in Tucson. For nearly 10 years the Territory was the scene of one of the most awful Indian wars in history, which practically stopped all progress there. On the Indian side it was entirely an affair of ambushes or of sudden raids from mountain strongholds, with burning and slaughtering, and carrying off of captives to be mutilated or outraged and then tortured to death. About a thousand men, women, and children perished.

Military operations were repeatedly stopped for a considerable period by the government commissioners, who wished to institute a policy of kindness, but finally Gen. George H. Crook was allowed to proceed without interruption in 1872-4, and put an end to the operations of the bands as a whole in 1874. But the government policy of concentrating them all on one reservation at San Carlos, Arizona, had unfortunate results. They objected to live with other bands with whom they were as much at feud as with the whites, and also to leave their chosen districts once given them by the government; but both Gen. Crook and his successor, who opposed the transfers, were removed to other departments. Again and again the bands escaped while being removed, and renewed their outrages; and for six years more there was a succession of bloody raids which swelled the total of horrors in the unfortunate Territory and New Mexico. In 1882 Crook was restored, and by tact and their confidence in him induced about 1,500, or over a fourth of them, to live on the reservation without rations. But the rest liked their life much too well to give it up; repeatedly they surrendered and returned with Crook only to break their promise and return to the warpath. The last time was in March 1886, when they escaped before entering Arizona and continued their outrages along the border for five months. The uproar against Crook for being duped (he had upheld the essential justice of their cause, and his belief in their willingness to behave, against the people) caused his replacement by Gen. Nelson A. Miles, who finally cornered the band and forced it to surrender. But the attempt to settle the Chirichuas and Hot Springs bands — the fiercest Indians on the continent, according to Gen. Crook — on a reservation in Arizona roused such a storm of protest from Arizonians that they were removed to Florida instead, then to Alabama, and finally to Fort Sill, Oklahoma, where they still remain, to the number of some 300. In all there are now about 5,200 Apaches. The name is sometimes applied to the Jicarillas, Mescaleros, and Lipans by reason of linguistic affinities; but incorrectly. See Bancroft, 'Native Races of the Pacific States,' Vol. XVII., 1880.

Apalachee, äp-a-lä'chē, or **Apalachi,** a tribe of Indians of the Muskhogean stock, first mentioned in 1526 as occupying the territory about Apalachee Bay and St. Mark's River in northwestern Florida and northward to the mountains to which they have given their name. Near the end of the 16th century Spanish Franciscan friars founded missions among them, till the war of the Spanish Succession, a century later, when the Spanish attempted to use the Indians as allies against the English Carolinas. Twice before the Spaniards had invaded Carolina from St. Augustine; and now, in 1702, they headed a party of 900 Apalachees and marched into Georgia. The Creeks, who were friendly to the English, not only warned them, but a party of 500 ambushed the Apalachees and routed them with great slaughter. The Carolinians determined to take the offensive: and after a fruitless expedition to St. Augustine in December 1703 one was undertaken into the Apalachian territory, which supplied that city with provisions and contained many Spanish forts. With 50 white men and 1,000 Creeks its leader stormed one fortified town and won a sharp battle, capturing several hundred Indians with women and children. Five other towns surrendered unconditionally, while a powerful cacique capitulated for his own safety. The expedition returned in March 1704 with 100 Indian slaves and 1,300 free Indians, who were settled among the Creeks. Twice more within the next four years Carolina invaded this territory with such results that in 1708 it held 850 Indian slaves in addition to what had been given to the Creeks. The Apalachees were thus practically obliterated; and though for a time they maintained their individual existence they finally became merged with the Creeks. See McCready, 'History of South Carolina Under the Proprietary Government' (1897).

Apalachee (ä'pa-lä'chē) **Bay,** a large arm on the south coast of Florida, in the Gulf of Mexico, having a breadth of about 90 miles and an extent inland of 50 miles. At the mouth of the St. Mark's River, which flows into the bay, is the town of St. Mark's.

Apalachicola, ä'pa-lăch-ĭ-kō-la, Fla., city, port of entry and county-seat of Franklin County, on Saint George Sound, Gulf of Mexico, at the mouth of the Apalachicola River; 85 miles southwest of Tallahassee; on the Carrabelle, Tallahassee & Georgia Railroad, and the following lines of steamships: Plant; People's; Merchants and Planters'; Gulf Navigation Co.; Central Gulf Coast Co.; and the Apalachicola and Chipola River line. The city has an important trade in timber and naval stores. The value of its foreign commerce in 1901 amounted to $370,000, the most of which was in export trade. The city has one national and several private banks. Pop. (1890) 2,727; (1900) 3,077.

Apalachicola, a river flowing from southeastern Georgia across Florida, and entering the Gulf of Mexico through Apalachicola Bay. It is navigable throughout its length of 90 miles and is formed by the union of the Flint and Chattahoochee Rivers.

Ap'anage, or **Ap'panage,** an allowance formerly received by the younger princes of a reigning house in which the right of primogeniture prevailed, from the revenues of the country. It consisted mostly in money, with the use of a residence and hunting grounds, attended frequently with the right of jurisdiction over these domains.

Apar, ä'pär, the three-banded armadillo (*Tolypeutes tricinctus*), which has three movable bands and is one of the small species able to roll itself into a ball. See ARMADILLO.

Aparri, a-pär'rē, Philippines, a town of the Cagayan province, on the river Cagayan, near its mouth. Pop. 11,265.

Apart'ment House, the term used in the United States to designate a structure intended to accommodate several families, each in its own set of rooms, which form a separate dwelling. Such structures are of comparatively recent introduction, but houses of this kind have long been built in Europe. In New York and other American cities there are now great blocks of such houses, which provide excellent and commodious dwellings at a lower rent than if

each were a separate building. See ARCHITECTURE (*American*).

Apat'elite (from the Greek *apatelos*, "deceitful"), a mineral related to raimondite, occurring in small yellow, friable nodules in the immediate vicinity of Paris, France. It has the probable composition $4Fe_2O_3.6SO_3.3H_2O$.

Ap'atite (from the Greek word *apate*, "deceit," in allusion to the fact that apatite is often confused with other minerals), a native phosphate of calcium, combined with fluorine or chlorine, and crystallizing in the hexagonal system, though also occurring massive. The crystals have a specific gravity of about 3.2 and a hardness of 5. Apatite is usually green, but it may occur white, or strongly red, yellow, brown, or blue. The common variety has the formula $(CaF)\ Ca_4(PO_4)_3$, and is known as "fluor-apatite"; but the fluorine is sometimes replaced to a considerable extent, or even wholly, by chlorine. In such cases the mineral is known as "chlor-apatite." A variety called "mangan-apatite" is also known, in which the calcium of the typical mineral is partially replaced by manganese. Apatite is widely distributed, and in many places occurs in vast deposits which are worked on a commercial scale on account of the value of the mineral as a phosphatic fertilizer. The Canadian apatite occurs massive or in large crystals. It was formerly extensively mined as a fertilizer, but its use has now been almost entirely supplanted by the "rock phosphate" of Florida, South Carolina, and Tennessee. See FERTILIZERS.

Apatite Group.— In mineralogy, a group of minerals crystallizing in the hexagonal system, and consisting of arsenates, phosphates, and vanadates of calcium and lead, associated with chlorine or fluorine. It contains apatite, pyromorphite, mimetite, vanadinite, hedyphane, pleonectite and svabite.

Ape (A. S. *apa*, Ger. *Affe*), in modern usage, a term describing an Old-World tailless monkey, such as the gorilla, orang-utan, chimpanzee, or gibbon, but originally an exact synonym for monkey and applied to any quadrumanous animal except the lemurs. For examples of this older usage see BABOON; MACAQUE; MONKEY. In its modern sense it applies particularly to the family *Simiidæ*, or anthropoid apes, found in the forests of the equatorial regions of the Old World and called "anthropoid" on account of their great resemblance to man. This likeness is especially marked in young individuals before the face has attained its full brutality of expression, the canine teeth their great size, and the skull its final thickening and growth into crests and ridges. Except for the shape of the jaw (which, instead of being curved, comes to a noticeable angle on each side with a canine tooth at the apex of each angle), and for the development of the skull already mentioned, as well as for the relative length of the arms and shortness of the legs, and the fact that the great toe is short and more or less opposable to the other fingers, an ape's skeleton is practically the same as man's, though larger and heavier in proportion to the body, and lacking certain curvatures of the spine which adapt the human frame to ease in an erect position. The brain-case, and the brain itself are much smaller than in man, yet similar in development, and the brain is much convoluted. The teeth are of the same number as man's and of like character. In certain divergences of structure exhibited between the inferior families of monkeys and man, the ape resembles man and differs from the monkeys.

The gibbons (noticeable for standing erect with less difficulty than any other apes), the chimpanzee (which has the largest brain), the gorilla, and the orang-utan, together with several extinct and fossil species, make up the anthropoid apes. All are clothed with hair on all parts of the body except the face and palms; they have no cheek-pouches, no tail, and either no trace or but very slight traces of the naked spots or callosities seen upon the buttocks of the lower apes. All are as large or larger than man, and all can walk upright, though they are more at ease in climbing than in walking. When on the ground they make their way slowly, sometimes closing the hands in order to walk on the knuckles instead of the palm, and either similarly closing the foot or walking on its side. Their food is mainly vegetable, yet their great strength, their intelligence, and their savage nature, place them among the most dangerous of wild animals. See CHIMPANZEE; GIBBON; GORILLA; ORANG-UTAN; PITHECANTHROPUS.

Ape'ga, the wife of Nabis, a tyrant of Sparta, who invented an infernal machine which he called after his wife, "Apega." It was a box exactly resembling his wife in her royal apparel, but the interior was full of spikes which wounded the victim enclosed in almost every part of the body. The "Iron Virgin" was a similar instrument employed by the Inquisition. It represented a woman of Bavaria, and the spikes were so arranged as to pierce the least vital parts in order to prolong the sufferings of the victim enclosed.

Apel, ä'pĕl, **Johann August**, a German author: b. in Leipsic, 1771; d. 1816. His 'Gespensterbuch' and 'Wunderbuch' were both popular, the former containing the bases for the text of Weber's opera of 'Der Freischütz. His 'Metrik,' which includes a survey of ancient prosody, is his best-known work.

Apeldorn, ä'pĕl-dôrn, or **A'peldoorn**, a notably attractive town of Holland, province of Guelderland, 17 miles north of Arnhem; with manufactures of paper, morocco leather, and copper-plates. The Loo, a favorite palace of the late king of Holland, is at Apeldorn. Pop. (1900) 25,761.

Apel'les, the most famous painter of ancient Greece and of antiquity: b. in the 4th century B.C., probably at Colophon. Attracted by the renown of the Sicyonian school, he studied at Sicyon. In the time of Philip he went to Macedonia, and there a close friendship between him and Alexander the Great was established. The most admired of his pictures was that of Venus rising from the sea and wringing the water from her dripping locks. His portrait of Alexander with a thunderbolt in his hand was no less celebrated. His renown was at its height about B.C. 330, and he died near the end of the century. See Houssaye, 'Histoire d'Appelles' (1867); Wustman, Apelles' Leben und Werke' (1870).

Ap'ennines, the chief mountain range of Italy, about 800 miles long and 25 to 85 miles wide, extending from Savona to Reggio in the

form of a bow. Geologically the Apennines resemble the Alps, and connect them with the north Sicilian and north African mountain ranges. Granite and crystalline schist (gneiss and mica-schist) are found in the Ligurian Apennines, especially in Calabria, south of the Gulf of Policastro. In the Apennines proper these older crystalline formations are entirely lacking. They consist principally of limestone, dolomite, sandstone, and marl, of the Chalk and Tertiary formations, in which occur strata of serpentine in the north, and sometimes trachyte and basalt, especially on Mount Vulture. In the northern Apennines, and also in the Tuscan highlands, there are large quantities of marl, shale, and blue-gray sandstone, which belong in part to the Chalk formation and in part to the early Tertiary. Limestone is found in large quantities in the composition of the whole mountain range. Carboniferous, Permian, Triassic, and Liassic deposits occur in the Apuan Alps, the famous marble of Carrara belonging to the Liassic or Triassic period. The Apennines are divided into six parts, according to the regions through which they pass, and these fall into three groups, the northern Apennines (including the Ligurian and Etruscan); the middle Apennines (the Roman Apennines and the Abruzzi); the southern Apennines (the Neapolitan and Calabrian). The Ligurian Apennines reach from the Col de Tenda, the geological boundary of the Alps, to the Pass of Cisa (about 700 miles). The southern slope falls abruptly to the sea, the northern slope gradually, with many valleys, toward the river Po. Numerous passes lead from the coast towns over the range, among them the Bochetta Pass, and the Giovi Pass from Genoa; and the Genoa-Alessandria Railroad has cut a tunnel through near the last-named pass. From there to the east the range almost doubles its width and increases in height. The eastern half, consisting of several parallel chains, is difficult to cross, and a serious hindrance to transportation. In this portion there are practically no thoroughfares except the railroad from Parma to Spezia.

The Etruscan Apennines, extending to the valley of the Metauro, have a southeasterly direction throughout and consist of several ranges, one in front of the other, like the links of a chain. The most noted peaks are in the northern part, the Alpe de Succiso (about 6,600 feet), Mount Cusna (over 6,900 feet), and Mount Cimone (7,103 feet), the latter being the highest peak in the northern Apennines. The northern portion includes the Apuan Alps, bounded by the valley of the Serchio, the Magra and the Antella, which reach the height of about 6,400 feet in Mount Pisano and are of pure marble (Carrara) on the slope toward the sea. The most important thoroughfare of the Etruscan Alps is the railroad from Bologna to Florence, which passes through a tunnel near Prachia; the La Fluta Pass, over which the road from Florence to Bologna passes, should also be mentioned. The Roman Apennines, beginning between the valleys of the Tiber and the Metauro, extend to the valley of the Tronto and Belino and consist of numerous parallel chains. In the north the main peak is Mount Catria (about 5,420 feet); in the south, the chain of the Sybilline Mountains rise to the height of 5,100 feet (Mount Vittore). The formation of the range here renders the crossing easy, and the railroad from Ancona to Florence and Rome crosses here. The Abruzzi extend southward from the valley of the Tronto, and in their eastern chain in Gran Sasso' d'Italia reach the greatest height in the whole Apennines (Mount Corno, 9,585 feet). The western chain, which, with the eastern, encloses the Plain of Aquila, has a height of almost 8,150 feet (Mount Velino), and south of the Pescara tunnel is the Majella range with a height of 9,200 feet. The Neapolitan Apennines extend from the valley of the Sangro and Volturno to that of the Crati, but their altitude is much less than that of the middle Apennines, the Matesian Mountains reaching the height of over 6,700 feet in Mount Miletto. Rounded, wave-like shapes prevail in this range. On the eastern range is the extinct volcano of Mount Vulture. The roads and railroads from the west to the east coast encounter no particular difficulty in crossing this range. In the south the Apennines reach again a noticeable height in Mount Pellino (7,450 feet) and slope abruptly to the valley of the Crati. The Calabrian Apennines consist of a small chain sloping abruptly to the Tyrrhenian Sea, and of the granite plateau of the Silagian Mountains with a mean height of 3,000 feet. This North Calabrian mountain land is separated from the South Calabrian by a neck of land between the Gulf of Santa Eusemia, and the Gulf of Squillace. The outer northerly and northeastern slope of the Apennines is gradual, the eastern slope almost everywhere so abrupt that on the Adriatic coast there is only room for a road. Since the Apennines on the west of the Gulf of Salerno lie near the coast, but in the north extend farther and farther away from it, there exists a three-cornered space in which lie the so-called Lower Apennines. The volcanic formation is especially characteristic of these mountains, and these regions are the classic ground of present and former volcanic action. Therefore there are here active and extinct volcanoes and hot springs, among them the springs of Voltena. The Lower Apennine region is divided into several parts by the broad valleys of the rivers flowing from the Apennines. Of these divisions the Tuscan highland is the most noted, ending on the south at the lower Tiber. In the interior are fertile plains sloping gently toward the valley of the Arno; in the west the highlands end with an abrupt slope, between which and the coast lie the plains of Maremma, from which rise a few single peaks. The part of the Lower Apennines between the valleys of the Tiber and the Garigliano includes two small mountain-groups: the Alban Mountains, famed for their beautiful scenery, and the Volsker Mountains extending as far as the coast near Terracina. West of these Volscian Mountains lies a plain whose northern portion includes the Campagna of Rome, while the southern part contains the Pontine marshes. The southernmost part of the Lower Apennines extends from the Garigliano to the mountain range of Castellamare, north of Salerno, and includes the plain of Campania, noted for its fertility as well as its beauty. From this plain rise several single volcanoes, including the extinct Mount Della Croce in the north and Vesuvius (4,200 feet) in the south. The climate is on the whole more severe than would be expected from the latitude and the position of

Italy, while the heat in summer reaches a degree almost unendurable in the low and sheltered valleys, and palms and other tropical vegetation can thrive on almost all the west coast; neither fruit nor grain grow on the exposed, windy heights, with their elevation of over 3,000 feet, and the trees are few and stunted. The region of vegetation may be divided into four sections: (1) The olive region to the 1,500-foot elevation, with Mediterranean flora, garden plants, and winter pasturage; (2) the region of the chestnut and oak, to the elevation of 3,000 feet, with agricultural products and chestnut woods; (3) the region of the beech and coniferous trees at the height of 3,000 to 6,000 feet; (4) the region of the shrubs and Alpine plants with summer pasturage extending to the highest peaks. In climate, therefore, the northern Apennines form a line of separation between north and south; only on their southern slopes does Italy really begin. The northern part only presents great difficulties in traveling. The mountains are now traversed by eight railroads, mostly by means of tunnels.

Apenrade, ä'pĕn-rä'dĕ. (Danish, *Aabenraa*), a seaport of Prussia, in the district of Schleswig-Holstein, on the Little Belt and in the Bay (fjord) of Apenrade. It is beautifully situated in a deep valley surrounded by woody heights and a fertile country. Apenrade has a school of navigation and carries on a considerable seafaring trade. It is a popular bathing resort and is a place of considerable antiquity. Pop. (1900) 6,616.

Ap'erture, in anatomy, zoology, botany, etc.: The aperture of a univalve shell is the opening or mouth. In mollusks which feed on vegetable matter it is entire; while in those which are animal feeders it has a notch or canal. In some families it has an operculum or cover. The margin of the aperture is called the peristome.

In optics, see MICROSCOPE; TELESCOPE.

Ape's Hill (Arabic, *Jebel Zatut*), the ancient Abyla, the extremity of a mountain range in northern Morocco, opposite Gibraltar, and one of the «Pillars of Hercules.»

A'pex, in mining, the highest point of outcrop of a mineral vein or lode. This is the common definition of the term as used by miners, although its legal significance must be interpreted in connection with the local conditions and cannot be defined in general terms. According to the Revised Statutes of the United States for 1872 the owner of a mineral claim which includes the apex is allowed to follow the vein along the dip for an indefinite distance without regard to the ownership of the overlying surface, so that the proper location of the apex is of the utmost importance in establishing the lines for a claim. It has been decided by the courts that the apex need not appear necessarily at the surface, and hence the term does not exactly coincide with the term outcrop. In the case of an inclined vein whose apex is concealed, but which outcrops at some point lower down, the right of mining is conveyed to the owner of the apex-claim in preference to the owner of the outcrop-claim. This law has been the cause of much confusion and of expensive litigation in settling the ownership of valuable mining properties in the western States. A wiser provision is that obtaining in most European countries, which grants the owner the right of mining only within the vertical limits of his claim.

Apex of the Sun's Way, a term signifying the point in the constellation Hercules to which the sun's motion in space is directed. This point is about in right ascension 18 hours 30 minutes, and declination 35° north. The point is therefore somewhat south of the zenith for most of the United States in the early part of the evenings of August. Of course this statement is meant to indicate the locality only in the most general way. That the solar system is moving toward this part of the heavens is indicated by the apparent spreading apart of the stars in this region, together with an apparent crowding together of the stars in the opposite direction, as the trees open in front of one walking through a grove and shut together behind him. The velocity of this motion is shown by spectroscopic observation to be about 11 miles per second. The movement, so far as observed, seems to be in a straight line, but may turn out to be in a vast curved orbit.

Aphan'esite, a-fan'e-sīt (from the Greek *aphanes*, «obscure,» in allusion to the difficulty of recognizing it by its crystals), a mineral now better known as CLINOCLASITE.

Aphanip'tera, an order of wingless insects having a sucker of three pieces and a true metamorphosis. The thorax is distinctly separate from the abdomen, and two horny plates mark the spots where wings would be in the higher insects. It contains the *Pulicidæ*, or fleas.

Aph'anite, ăf'ă-nīt (derivation same as for aphanesite), a variety of the rock known as diorite, in which the constituent minerals occur in such small grains that the aggregate rock appears almost (or quite) homogeneous, except when examined through a lens.

Aphasia, the designation of a disorder of speech due to disturbance of its brain mechanism independently of any muscular defect. This mechanism is complex and is usually divisible into two parts, the receptive, or sensory, and emissive, or motor. To the former belong those parts of the brain that store concepts of spoken words or written words; to the latter those parts concerned in co-ordinate speech or in writing. Thus aphasia may be of at least four different and independent types. Frequently it is a combination of one or more of these. The centre in the brain that stores intellectual auditory impressions is located in the first temporal convolution. Any injury to this part of the speech mechanism may produce auditory aphasia, or word deafness. A patient thus affected is able to hear words and to speak, but he does not comprehend what is being said to him. He has lost his hearing word memories, and his own language is as a foreign language that he hears but cannot comprehend. In an analogous manner, if there is disorder of the occipital lobes, about the calcarine fissure, or of its related fibre tracts, a patient may have visual aphasia, or word blindness. His own written

language might as well be in Arabic, for he has lost all his memory of written words. These types of aphasia are much less common than the true type of motor aphasia, or aphemia. In this the trouble is in the third left frontal convolution in the brain, Brocas convolution, or its related fibre tracts, and a patient thus affected has lost the power to say the words he desires to say. He is perfectly able to talk, may repeat words, but knowing in his mind precisely what he wishes to say is unable to express it, not because of any failure of the muscular power of the tongue to articulate, but because of the defect in the storage centre or its fibre paths for motor speech. A fourth type is *agraphia*, in which the affected patient is unable to write with understanding the words with which he is familiar. The site of the lesion here is undetermined. It usually accompanies motor aphasia. There are also forms of combined aphasia in which the fibre tracts from one centre to another are cut off. These make paraphasias, and their symptoms are extremely complex. Aphasia in its various forms may differ very widely in its extent. It may be very slight or very profound. It may be temporary or permanent, depending on the nature and extent of the brain injury. Aphasia is most frequently a symptom of hemorrhage from some artery or arteries in the brain; it may be caused by the growth of a tumor or result from an injury. The treatment is that of the causing disease. In the sensory aphasias education of the non-affected areas is of great importance. If there is word blindness, the memory for spoken symbols should be cultivated, and *vice versa*. See SPEECH, DEFECTS OF.

Aphe'lion, that part in the orbit of the earth (or any other planet) which is farthest from the sun.

Aphemia, a term employed to designate a motor aphasia. See APHASIA.

A'phis, a plant-louse of the family *Aphididæ,* order *Hemiptera.* Aphides are among the most abundant of insects and do much injury to vegetation by their habit of sucking the sap of leaves and stems of plants. They are usually very small, never over a quarter of an inch in length. Their mouth-parts form a slender beak adapted for puncturing leaves and sucking the sap. Their antennæ are from five- to seven-jointed, and generally longer than the body. The ocelli are wanting, and the beak is three-jointed and developed in both sexes. The legs are long and slender, with two-jointed tarsi. The males and females are winged, and also the last brood of asexual individuals, but the early summer broods are wingless. Their bodies are flask-shaped, being cylindrical, the abdomen thick and rounded, and in aphis and lachnus provided with two tubes on the sixth segment for the passage of a sweet fluid (honey-dew) secreted from the stomach, which attracts crowds of ants. (See ANT.) The wings are not net-veined, having few veins, which pass outward from the costa. They are usually green in color, with a soft powdery bloom exuding from their bodies. Bonnet first discovered that the summer brood of wingless individuals were born of virgin parents, hatched from eggs laid in the autumn, and that the true winged sexes composed the last generation, which united sexually, and that the female laid eggs in the autumn which produced the spring brood of asexual wingless individuals.

In the early autumn the colonies of plant-lice are composed of both male and female individuals. These pair, the males then die, and the females begin to deposit their eggs, after which they die also. Early in the spring, as soon as the sap begins to flow, these eggs are hatched, and the young lice immediately begin to pump up sap from the tender leaves and shoots, increase rapidly in size, and in a short time come to maturity. In this state it is found that the whole brood, without a single exception, consists solely of females, or rather, and more properly, of individuals which are capable of reproducing their kind. This reproduction takes place by a viviparous generation, there being found in the individuals in question young lice which, when capable of entering upon individual life, escape from their progenitors and form a new and greatly increased colony. This second generation pursues the same course as the first, the individuals of which it is composed being, like those of the first, sexless, or at least without any trace of the male sex throughout. These same conditions are then repeated, and so on almost indefinitely, experiments having shown that the power of reproduction under such circumstances may be exercised, according to Bonnet, at least through nine generations, while Dural thus obtained eleven generations in seven months, his generations being curtailed at this stage not by a failure of the reproductive power, but by the approach of winter, which killed his specimens. Huber observed that a colony of *A. dianthi,* which had been brought into a constantly heated room continued to propagate for four years in this manner without the intervention of males, and even in this instance it remains to be proved how much longer these phenomena might have been continued.

Certain species feed on the roots of plants, as asters, lettuce, grasses, etc., and these also attract numerous ants. The cornplant-louse has been found by Forbes to hibernate in the wingless, asexual form in the earth of previously infested corn-fields. In the spring an ant (*Lasius alienus*), which runs its tunnels along the principal roots of the corn, collects the aphides and conveys them into its galleries, where they are watched and protected. The white-pine aphis (*Lachnus strobi*) is destructive to young white-pine trees. Another aphid is the grape *Phylloxera* (q.v.). The woolly aphids (*Schizoneurà tessellata*) flock on the stems of the alder, their bodies concealed by a flocculent mass of wax. Another destructive species is the apple woolly louse (*S. lanigera*). Aphides can be exterminated by frequent spraying.

A'pis (Egyptian. *Hapi*), a bull at Memphis to which divine honors were paid by the ancient Egyptians, and which was regarded as the representative of Osiris. It was necessary that he should be black, with a triangle of white on the forehead, a white spot in the form of a crescent on the right side, and a sort of knot like a beetle under his tongue. Other marks are also mentioned. When a bull of this description was found he was fed four months in a building facing the east. At the new moon he was led to a splendid ship with great solemnity, and conveyed to Heliopolis, where he was fed 40 days more by priests and women, who performed before him various indecent ceremonies. From Heliopolis the priests carried him to Memphis, where he had a temple, two chambers to dwell in, and a large court for exercise. His actions were thought to have prophetic significance, and he was believed to impart prophetic power to the children about him. His birthday was celebrated every year, when the Nile began to rise. The festival continued for seven days, and it was said that the crocodile was always tame as long as the feast continued. Notwithstanding all this veneration, the bull was not suffered to live beyond 25 years, the reason of which is probably to be found in the astronomical theology of the Egyptians. The death of Apis, however, excited universal mourning, which continued till the priests had found a successor to him. As it was extremely difficult to find one with all the above distinctions, fraud was often practised by the priests.

Ap'johnite, a native manganese alum, or hydrated sulphate of aluminum and manganese, found in fibrous form and as incrustations at Lagoa Bay, South Africa, and in Sevier County, Tennessee. It is variable in composition, but some analyses indicate $MnSO_4.Al_2(SO_4)_3 + 24H_2O$. It is usually white or nearly so, and tastes much like common alum.

Aplanatic Lenses, a term applied to lenses nearly or quite free from spherical aberration. If the curved surfaces of a single convex lens are portions of spheres, the rays of light from one point of an object are not accurately brought together at one corresponding point of the image, the rays passing through the outer portions of the lens being too much refracted. The result is a distorted image. Theoretically it is easy to correct this error by substituting ellipsoidal surfaces for the spherical, but such surfaces cannot be accurately constructed. Spherical aberration is corrected, in practice, by combinations of two or more lenses in one, the surfaces being of differing curvatures. The results are quite satisfactory, and the method is applied in the manufacture of objectives and eye-pieces for telescopes and microscopes, as well as in the making of lenses to be used in photography.

Apoc'alypse (Greek, *apokalypsis*, from *apokalyptō*, I reveal), the name frequently given to the last book of the New Testament. It is generally believed that the Apocalypse was written by John in his old age, at the end of the first century (95–97 A.D.), in the Isle of Patmos, whither he had been banished by the Roman emperor Domitian. Though commonly regarded as genuine in the first centuries of Christianity, critics have not been wanting who have doubted the evidence of its being the work of St. John. Its genuineness was maintained by Justin Martyr (c. 150), Irenæus (195), Clement of Alexandria (200), Tertullian (207), and many others; and doubted by Dionysius of Alexandria (240), Cyril of Jerusalem, Chrysostom, and, nearer our own times, by Luther and a majority of eminent German commentators. In recent times a composite authorship has been suggested and some have regarded it as a Jewish work adapted by a Christian writer. The Apocalypse, on account of its metaphorical language, has been explained differently by almost every interpreter, and for the same reason it has furnished all sorts of sects and fanatics with quotations to support their creeds or pretensions. There can be no doubt that the hopes of the early Christians and the severe persecution they endured led them to regard the Roman empire as the object of prophetic denunciation, and the coming of Christ and the millennium as near at hand. When, under Constantine, however, the Christians became dominant and prosperous, the empire was considered as the scene of a millennial development, and in course of time the barbarous hordes who were closing round Rome were regarded as fulfilling the woes predicted in the Apocalypse. At the Reformation the Protestants identified Babylon with papal Rome, and the second beast of Antichrist with a universal pontiff. The modern interpreters may be divided into three schools: namely, the historical school, who hold that the prophecy embraces the whole history of the Church and its foes from the time of its writing to the end of the world; the Præterists, who hold that the whole, or nearly the whole, of the prophecy has been already fulfilled, and that it refers chiefly to the triumph of Christianity over Paganism and Judaism; and the Futurists, who throw the whole prophecy, except the first three chapters, forward upon a time not yet reached by the Church — a period of no very long duration, which is immediately to precede Christ's second coming. The Apocalypse contains 22 chapters, which may be divided into two principal parts. The first comprises "the things which are"— that is, the then present state of the Christian Church, including the epistolary instructions and admonitions to the angels or bishops of the seven churches of Ephesus, Smyrna, Pergamos, Thyatira, Sardis, Philadelphia, and Laodicea, situated in Asia Minor. The second part comprehends a prediction of "the things which shall be hereafter," referring either to the future state of the Church through succeeding ages, from the time of the apostle to the grand consummation of all things, or to the state of the souls of men after the general resurrection.

Apocalyptic Literature, the designation of a large body of literature originating in Jewish and continued in early Jewish Christian circles. The most of it was produced between 200 B.C and 200 A.D. In a broad sense it had for its theme the future triumph of the kingdom of God. The most important works were written in times of great stress, when persecution or

oppression weighed heavily on the Jews (or Christians, as the case might be). At such times consolation was found in the thought that God would surely cause his kingdom to triumph by punishing the wicked and rewarding his saints.

The beginnings of Apocalyptic literature are to be found in the Old Testament writings of the Exile period. The main theme of the prophetic messages of these times was, of course, the solution of the problems directly concerned with Israel in exile, and the teaching was mainly in the nature of rebuke for sin, instilling loftier and purer conceptions of God and sustaining the hope of a restoration to the old land, there to enjoy a long and happy existence. But at times the future unveiled by prophecy took on a peculiar aspect,— on an imaginary arena, in an undated distant time, the great forces of the world and of God were seen to be in conflict. At first, as in Ezekiel xxxviii. and xxxix., the scene of the struggle is this earth, and the doom of the defeated hosts is simply their destruction by slaughter. The same may be said of the apocalyptic strains in Zech. xiv. and Joel iii. 9–21. It is this unveiling of the future, not as to single events or specific historical movements, but as to its processes and great world-wide and age-long conflicts, that is technically termed *apocalyptic* (from the Greek ἀποκαλύπτειν to unveil). The foundation being thus laid in exilic and early post-exilic days, when the next great crisis came in the deadly struggle with Syria (168–142 B.C.) it was but natural that a gifted spirit should again make use of this form of prophetic instruction. Hence we have in Daniel vii.–xii. such unveilings of the course of history in which the certain triumph of Jehovah's eternal kingdom is the inspiring motive. But now Apocalyptic perception has opened its vision not simply on the earthly phases of the struggle, but on its eternal outcome for the evil and the good (cf. Dan. xii.). Henceforth these phases are to receive special attention from Apocalyptic writers. The book of Daniel gave Judaism a powerful impetus in this direction, and in the succeeding centuries Apocalypses were put forth which made bold to pretend to uncover the secret counsels of God's purposes and the mysteries of heaven and hell. The most refined and purified of all such works is the great Christian Apocalypse of the Apostle John. With the single exception of the New Testament Apocalypse all the works of this nature are pseudepigraphic. In order to give them the appearance of predictions uttered long before the times in which they were actually written they were put forth under the name of some ancient worthy, as Enoch, Abraham, Moses, etc., as though spoken or written by him. Between 20 and 30 Apocalyptic works are known to have been once in circulation. Those of Jewish origin, among which the most influential and comprehensive were the Book of Enoch and 2 Esdras (the latter in the Old Testament Apocrypha) were taken over into Christian circles, and there often recast and made to do service as Christian books. After about 200 A.D. Christian scholars strongly disapproved of the use of the various Apocalypses, except those in the Bible and 2 Esdras, and they gradually dropped out of use. Many are now known only by name.

EDWARD E. NOURSE.

Apoc'alyp'tic Number, the mystic number 666, which, according to some authorities, should be 616, mentioned in Revelation xiii. 18. As early as the second century ecclesiastical writers found that the name Antichrist was indicated by the Greek characters expressive of this number, numbers being expressed in Greek by the letters of the alphabet. By Irenæus the word *Lateinos* was found in the letters of the number, and the Roman empire was therefore considered to be Antichrist. Another solution is *Neron Kesar* (Hebrew form of Nero Cæsar). Omitting the *e's* and the *a*, not written in ancient Hebrew, we get 666 as the value of the letters.

Apochrom'atic Lens. See LENS.

Apoc'rypha (Greek, "things concealed or spurious"), a term applied in the earliest churches to various sacred or professedly inspired writings, sometimes given to those whose authors were unknown, sometimes to those with a hidden meaning, and sometimes to those considered objectionable. It is specially applied to the 14 undermentioned books written during the two centuries preceding the birth of Christ. They were extant, not in Hebrew, but in Greek, and were accepted by Alexandrian, though not by Palestinian Jews. They were incorporated into the Septuagint, and thence passed to the Vulgate, but the Greek Church excluded them from the canon in 360 at the Council of Laodicea. The Latin Church treated them with more favor, and the Council of Trent, in the fifteenth century, definitively declared the acceptance of these books as part of the canon to be of faith. The Anglican Church says they may be read for example of life and instruction of manners, but that the Church does not apply them to establish any doctrine. All other Protestant churches in Great Britain and America ignore them. The following 14 books form the Apocrypha of the English Bible: The first and second Books of Esdras, Tobit, Judith, the rest of the Book of Esther, the Wisdom of Solomon, the Wisdom of Jesus the son of Sirach, or Ecclesiasticus, Baruch the Prophet, the Song of the Three Children, Susanna and the Elders, Bel and the Dragon, the Prayer of Manasses, and the first and second Books of the Maccabees. Besides the Apocryphal books of the Old Testament there are many spurious books composed in the earlier ages of Christianity, and published under the names of Christ and his apostles, or of such immediate followers as from their character or means of intimate knowledge might give an apparent plausibility to such forgeries. These writings comprise: 1st, the Apocryphal Gospels, which treat of the history of Joseph and the Virgin before the birth of Christ, of the infancy of Jesus, and of the acts of Pilate; 2d, the Apocryphal Acts of the Apostles; and 3d, the Apocryphal Apocalypses, none of which have obtained canonical recognition by any of the Churches. See Cowper, 'Apocryphal Gospels, Etc.'

Ap'ocyna'ceæ, the designation of an extensive natural order of monopetalous exogenous plants, characterized by perfectly symmetrical flowers, the segments of the corolla all twisted one way like a catherine-wheel, five distinct stamens, a superior ovarium, which when ripening opens into two parts that diverge from each other at right angles; fruit follicular or capsular, or drupaceous or baccate, double or

single. The order consists of trees or shrubs, many of whose stems yield, when wounded, a copious milk, usually poisonous. Generally found in tropical regions, they appear to be most abundant in the hot parts of Asia, are less common in the tropics of America, and still more rare in Africa. About 100 genera, including 566 species, have been enumerated. The plants of this order are in many cases poisonous, and very generally to be suspected, although in some cases they are used medicinally, and in others have an edible fruit. One of the most deadly plants of the order is the *Tanghina venenata.* The kernel of the fruit, although not larger than an almond, is sufficient to kill 20 men; it was formerly used in Madagascar as an ordeal. The common oleander (*Nerium oleander*) is a formidable poison and death has resulted from eating its flowers.

Apodictic Judgments, a logical term adopted by Kant from Aristotle to distinguish judgments or conclusions which are beyond contradiction from those which are merely empirical; or to put it differently, a judgment or conclusion which is founded on the impossibility of the opposite, not upon grounds of experience is an apodictic judgment.

Apollinarians, a sect of Christians who maintained the doctrine that the Logos (the Word) holds in Christ the place of the rational soul, and consequently that God was united in him with the human body and the sensitive soul. Apollinaris, the author of this opinion, was, from 362 A.D. till about 382 A.D., bishop of Laodicea, in Syria, and a zealous opposer of the Aryans. As a man and a scholar he was highly esteemed, and was among the most popular authors of his time. He formed a congregation of his adherents at Antioch, and made Vitalis their bishop. His teaching was condemned at Alexandria in 362; by Pope Damasus in 375; and in the Council of Constantinople in 381. The Apollinarians, or Vitalians, as their followers were called, soon spread their sentiments in Syria and the neighboring countries, established several societies, with their own bishops, and one even in Constantinople. The sect was denounced in 428 by imperial edict, and its members gradually returned to the Church or became Monophysites (q.v.).

Apol'lo, son of Zeus (Jupiter) and Leto (Latona), who being persecuted by the jealousy of Hera (Juno), after tedious wanderings and nine days' labor, was delivered of him and his twin sister, Artemis (Diana), on the island of Delos. He was the most important of the Olympian deities after Zeus and appears in mythology as the god of poetry, music, and prophecy, the patron of physicians and shepherds, and the founder of cities. He aided Zeus in the war with the Titans and the giants, and destroyed the Cyclopes because they forged the thunder-bolts with which Zeus killed his son and favorite Asklepios (Æsculapius). All of the male sex dying suddenly without previous sickness were supposed to be smitten by the arrows of Apollo. In the oldest poems Apollo is exhibited as the god of song, being known in this function as Apollo Citharœdus. Two statues of Apollo Citharœdus are extant, one of them at the Glyptothek in Munich, the other at the Vatican, but their date is unknown. In the festivals of the gods and those of men in which they took part he plays and sings while the Muses dance around him. According to some traditions he invented the lyre, though this is generally ascribed to Hermes (Mercury). Marsyas, who ventured to contend with him on the flute, was conquered and flayed alive by the god. Apollo had another contest with Pan, in which the former played on the lyre, the latter on the pipe. Tmolus had already decided in favor of Apollo, when Midas, opposing the sentence, was decorated with a pair of ass's ears for his stupidity. That Apollo had the gift of prophecy appears from the Iliad, where he is said to have bestowed it upon Calchas and Cassandra; and in the Odyssey mention is made of an oracular response delivered by him in Delphi. The oracle at this place became very famous. He also revealed future events at Abæ in Phocis, Didyma near Miletus, Claros near Colophon in Ionia, Tenedos and Patara in Lycia. Apollo, in later times, came to be regarded as the god of physic, and was represented to be the father of Asklepios, the god of healing. He is reported to have taken charge for a long time of the herds of Admetus, according to some authorities voluntarily, according to others compelled by Zeus, on account of the murder of the Cyclopes, or the serpent Python. As a builder of cities, the founding of Cyzicum, Cyrene, and Naxos in Sicily is ascribed to him, while Homer relates that he built the walls of Troy together with Poseidon (Neptune), and afflicted the city afterward with a pestilence, because Laomedon defrauded him of his pay. According to the poets and sculptors, Apollo, with Ares (Mars), Hermes (Mercury), and Dionysos (Bacchus), belongs to the beardless gods, in whom the dawnings of early manhood appear. He is figured with a bow, a quiver and plectrum, a serpent, a shepherd's crook, a griffin and a swan, a tripod, a laurel, an olive-tree, etc. He was originally the sun-god; and though in Homer he appears distinct from Helios (the sun), yet his real nature is hinted at even here by the epithet Phœbus, the radiant or beaming. In later times the view was almost universal that Apollo and Helios were identical, and by this theory of his origin we can easily understand how he should be regarded as the god of pastures (Nomios) and of flocks (Karneios), the god that protects and causes the fruits of the field to grow, the god that gives fair winds to mariners (Embasios), etc. As he slew the Python, that is, the hostile powers of darkness, with his arrows (the sunbeams), so in later times he was looked on as the averter of evil, the bringer of help, and the punisher of overweening pride (as in the story of Niobe). From being the god of light and purity in a physical sense he gradually, as he became endowed more and more in the Greek mind with an ethical character, became the god of moral and spiritual light and purity, the source of all intellectual, social, and political progress. Thus he came to be considered as the god of song and prophecy, the god that purifies after the commission of crimes, that averts and heals bodily suffering and disease, the institutor and guardian of civil and political order, and the founder of cities. Though not one of the original gods of the Romans, his worship was introduced at Rome at an early period, probably in the time of the

Tarquins. Among the ancient statues of Apollo that are extant the most remarkable, and in the judgment of the learned and acute Winckelmann the best and most perfect that art has produced, is the one called the Apollo Belvedere, from the Belvedere Gallery in the Vatican at Rome; also called the Pythian Apollo, because it is supposed that the artist has represented the god in the moment of his victory over the serpent Python. This statue was found in the ruins of Antium in 1503. It is conjectured to be a careful copy of a Greek original, perhaps of the 4th century B.C., or possibly a century or more later.

Apol'lo Belvedere, bĕl'vā-dā'rā. See APOLLO.

Apollonius, Pergæus, from Perga in Pamphylia; lived about 250–200 B.C. He was educated in Alexandria under the successors of Euclid, and became one of the greatest mathematicians of antiquity, being commonly called the "Great Geometer." His most important work was a treatise on conic sections, in eight volumes, of which the first four, with the commentary of Eutocius, are extant in Greek, and all but the eighth volume in Arabic. We have also introductory *lemmata* to all the eight by Pappus, edited by Halley, 'Appolonius Pergæus Conic,' lib. VIII., c., Oxon. 1710. fol

Apollo'nius of Tyana, a Pythagorean philosopher, b. at Tyana, in Cappadocia, about whom many wonderful stories are told. He was born in the beginning of the Christian era, early adopted the Pythagorean doctrines, abstaining from animal food and living in the simplest manner, and according to the Pythagorean precept maintained a rigid silence for five years. He traveled in Asia, disseminating his doctrines and doing many wonderful things, and proceeding as far as India, where he became initiated into the doctrines of the Brahmans. When Domitian ascended the throne Apollonius was accused of having excited an insurrection in Egypt in favor of Nerva, but readily submitting to a trial he was acquitted. After this he went once more to Greece and passed over to Ephesus, where he opened a Pythagorean school, and died in 96, or, according to others, 110 A.D.

Apollyon, ă-pŏl'lĭ'ŏn, or ă-pŏl'yŭn, a rendering of the Hebrew Abaddon, meaning destruction. Apollyon is personified as the keeper of the bottomless pit.

Apolo'gia pro Vi'ta Su'a, the title given by Cardinal Newman to the account of his religious career, published in 1865. It was called forth by Charles Kingsley's accusation that "Truth, for its own sake, has never been a virtue with the Roman clergy. Father Newman informs us that it need not and on the whole ought not to be: that cunning is the weapon which heaven has given to the saints wherewith to withstand the brute male force of the wicked world, which marries and is given in marriage. Whether his notion be doctrinally correct or not, it is at least historically so." Newman deeming the time ripe for a full and searching justification of his position, and of the position of his brother clergy, published the 'Apologia' the next year. Its supreme value is its intimate revelation of a luminous spirituality, of a personality of lofty refinement and beauty.

Apologetics, the department of theological science which deals with the defense of the Christian faith. It differs from dogmatics which strives to reduce the doctrines of religion to a systematic form; and from polemics, which is the science of controversy, and while its subject matter comprises the differences found in different schools of believers, apologetics deals with attacks upon the faith which are made by unbelievers. Apologetics may be again distinguished from apologies. The former has to do with the fundamental principles of the religion and with the methods of defense which apply to all attacks, but an apology has to do with some special form of unbelief. The former is the science of which the latter is an application. Yet, apologetics as a science may be best understood through its historical applications and the distinction named is made more readily in theory than exhibited in detail.

Owing to the nature of Christian theology as historically formulated, apologies have fallen under two main divisions, popularly known as natural theology and the evidences of Christianity. The former is usually put before the latter. It discusses the nature of God and the proofs of His existence as revealed to us in nature. It may also investigate the nature of man, his moral sense, the freedom of his will, and his capacity for knowing God. Its chief reliance has been upon four arguments: the ontological, which starts from our idea of a perfect being and shows that it implies actual existence: the cosmological, which from the long line of causes and effects, each contingent, argues backward to a first great cause, which is itself uncaused; the teleological, which shows the marks of design in nature, and from them argues to a great designer; the moral, which starts with the moral sense in man and argues to a holy and righteous maker. Some writers add an æsthetic argument, from our sense of beauty and its gratification in the universe. Then these various arguments are combined and the perfect being is shown to be the first great cause, righteous, wise, and a person whom therefore we call God.

The evidences of Christianity assume the existence of such a God, and from this basis prove Christianity to be His peculiar revelation, constituting the absolute religion. This proof ordinarily is divided into two great divisions, external and internal. The external proofs are miracles and completed prophecy, which evince a power and wisdom which are Divine and guarantee the Divine authorship of the writings which they authenticate. The external proofs include also the historical evidence to the genuineness of the scripture writings. The internal evidences show the adaptation of the contents of the Bible to the needs of men, their agreement with the highest teachings of reason, and their elevating and purifying effect upon the mind and life. A further argument is based upon the experience of the Christian as testifying to the truth of the doctrines involved.

This argument in both divisions, natural theology and the evidences of Christianity, occupies the chief place in the text-books, but, evidently, it is a form of specific apology, and at best only in part illustrates essential apologetics. This appears from a wider survey for the argument as stated above, while it meets a special situation, neither represents the actual argumentation in the first ages of the Church

nor in our own day. Even in the New Testament some of the writings have an apologetic purpose. Christianity in its early form met two opponents, Judaism and heathenism. To the first, the apostolic writers attempted to prove its truth by showing it as foretold in the Old Testament, and as completing the earlier Scriptures. When Christianity encountered Greek thought the situation was wholly different, and the apologists formulated the contents of the Gospel in a manner which appealed to the common sense of all the serious thinkers and intelligent men of the age. That is, Christianity was presented as completing, or at least harmonizing with, the later Greek philosophy. In this it succeeded and then ensued a long period when apologetics was in abeyance. The intellectual life of the Church was engaged in formulating dogmas and in conflicts with heresy. Only long after the Reformation was the strife renewed with men who seriously denied the truth of Christianity.

In the end of the 17th century, and the beginning of the 18th century, the minds of English Churchmen were engaged by the Deistic controversy. This had to do with the evidences of Christianity. The Copernican astronomy, changing men's conceptions of the physical universe, the discovery of China, or better its rediscovery and its effect upon the imagination of thoughtful men, and the attacks of the British clergy upon the miracles of the Roman Catholic Church, brought on a crisis. The new astronomy suggested the thought that the God of so great a universe could not be identical with Jehovah, the God of a Semitic people; nor could men conceive of the earth, no longer central but a mere planet, as the scene of the drama of the incarnation and the redemption; the consideration of China with the thought of its relatively high civilization suggested that if China had got on so well without the special teaching of the gospel with the light of reason only, the special revelation must also be valueless to Englishmen; and the attacks of the clergy upon the Roman Catholic miracles as the frauds of priests led to the position that all miracles, including those of the Bible, may be put into the same category. It was further urged, that the description of Jehovah in the Bible and in the doctrines of the Church does not accord with the righteousness and wisdom and power of the God disclosed by nature. The conception of nature as a vast machine was taking possession of men's minds, and God was thought to be the maker and starter of the machine, and as having no further occasion to interfere with its running. He was not denied, therefore, but He was made infinitely remote, and there seemed no opportunity for miracle, redemption or prayer. The attack called forth a multitude of replies, the 'Analogy' of Bishop Butler being the most effective and distinguished. He argued that revealed and natural religion are not opposed, but that the second supplements the first, and that its peculiarities are what we should expect from a study of nature itself; and that further, the difficulties urged by the Deists against the God of the Bible lie with equal force against their own teaching of the God of nature. It was further argued, in particular, that the account of the gospel miracles is to be accepted, because the witnesses were competent, and moreover had everything to lose and nothing to gain by their invention, proving their sincerity by dying as martyrs. The Wesleyan revivals were perhaps more influential than the arguments of the apologists by supplying the powerful evidence of the effectual working of Christianity in the hearts and lives of men. From England the controversy was carried to France, and to Germany, with phases too varied for even the briefest review here.

In the 19th century, from the middle decades on, the apologetic warfare was renewed, with issues far more fundamental. Already Hume had stated positions which threatened the beliefs of Churchmen and of Deists alike, and under the influence of an extreme empiricism, reinforced by influences from German philosophy, men denied that God could be known at all. Hence apologetics again busied itself with the first division of topics, and discussed man's capacity for knowing the Infinite, and reviewed all the evidences for God's existence in the light of the modern science of knowledge. The progressive establishment of the scientific conception of the universe also revived the discussion as to miracles and forced a renewed examination of the whole subject. In addition, the historic credibility of the gospel narrative and the authenticity of the Biblical writings have been re-examined from many points of view, while the discovery of the ancient religions of the past and of the living religions of Asia have caused prolonged debate as to the uniqueness and the absoluteness of the Christian teachings. Hence, the apologist is engaged in a discussion which involves philosophy, science, history, comparative theology, and criticism.

In general, we may put apologists at present into three classes; those who hold substantially the old positions and seek in part by compromise and in part by adaptation to show that their essential truth may be maintained notwithstanding the progress in philosophy and science; those who abandon the old arguments, and overcome the conflict between science and philosophy on the one hand and theology on the other, by adopting wholly the modern views and reconstructing theology by their aid; and those who attempt to discriminate between religion and science and philosophy, and by penetrating more completely into its essence to find an independent basis for the religious life which shall abide however men's views may change in these other departments. Particular arguments in reply to special attacks are of less moment than a discussion of the meaning and essence of Christianity itself, and of the principles which underlie all defenses of its truth. That is, this age needs not so much an apology or defense of Christian truths as a thoroughgoing study of the science of apologetics itself.

GEORGE WM. KNOX, D.D.,
Professor of Philosophy and History of Religion, Union Theological Seminary.

Ap'ologue, a story or relation of fictitious events intended to convey some useful truth. It differs from a parable in that the latter is drawn from events that pass among mankind, whereas the apologue may be founded on supposed actions of brutes or inanimate things. Æsop's fables furnish excellent examples of apologues.

Apol'ogy, a term at one time applied to a defense of one who is accused, or of certain doctrines called in question, but at present commonly applied to an acknowledgment of error. The apologies of Socrates attributed to Plato and Xenophon are works of the first-named character. Later rhetoricans wrote upon the use of apologies and caused them to be composed by their scholars. Of this sort are the Apologies of Libanius. Thus the name passed over to Christian authors, who gave the name of apologies to the writings which were designed to defend Christianity against the attacks and accusations of its enemies, particularly the pagan philosophers, and to justify its professors before the emperors. Of this sort were those by Justin Martyr, Athenagoras, Tertullian, Tatian, and others. There are also apologies for the doctrines of particular sects; for example, Robert Barclay's 'Apology for the People in Scorn called Quakers.'

Apol'ogy for the Life of Colley Cibber, An, an autobiography published in 1740, when the author, poet-laureate, actor, and man-about-town was in his 70th year. In the annals of the stage this curious volume holds an important place as throwing light upon dramatic conditions in London after the Restoration, when the theatre began to assume its modern aspect.

Ap'omor'phine. See MORPHINE.

Aponeurosis. See TENDON.

Apoph'yllite, ă-pŏf'ĭ-līt (from the Greek words *apo,* «off,» and *phyllon,* «leaf,» in allusion to the tendency of the mineral to separate into thin leaves before the blowpipe), a native hydrated silicate of calcium and potassium, having the general formula $K_2O.8CaO.16SiO_2.16H_2O$, but with some portion of the oxygen replaced by fluorine. It crystallizes in the tetragonal system, and also occurs massive. Its crystals are usually white or gray, with a pronounced pearly lustre on the basal plane, and a vitreous lustre elsewhere. Apophyllite cleaves easily into thin folia parallel to the basal plane. Its hardness is from 4.5 to 5, and its specific gravity about 2.3. It occurs in many parts of the world. Beautiful crystals, 3 or 4 inches across, are found in India, and others nearly as large have been found at Bergen Hill and Paterson, N. J.

Apoplexy. See BRAIN DISEASE.

Aposiopesis, ăp'ō-sĭ-ō-pē'sĭs, a rhetorical term denoting a sudden break or stop in speaking or writing, usually for mere effect or a pretence of unwillingness to say anything on a subject; as, «his character is such —— but it is better I should not speak of that.»

Apos'tasy (Greek, *apostasis,* a standing away from), a term signifying a renunciation of opinions or practices and the adoption of contrary ones, and usually applied to renunciation of religious opinions. It is always an expression of reproach. What one party calls apostasy is termed by the other conversion. History mentions three eminent apostates — Julian the Apostate, who had never been a Christian except nominally and by compulsion; Henry IV., king of France, who thought that «Paris vaut bien une messe,» and that of course all France was worth the whole Catholic faith; and William of Nassau, the stadtholder, who separated himself from the Roman Catholic Church and became a Protestant. The statute 9 & 10 of William III. cap. xxxii., provides that if any person educated in or having made profession of the Christian religion shall deny it to be true, he shall be rendered incapable of holding any office for the first offense, and for the second shall be made incapable of bringing any action, of being guardian, executor, legatee, or purchaser of lands, and shall suffer three years' imprisonment without bail. This act is commonly called the «blasphemy act.»

A Posteriori. See A PRIORI.

Apos'tle (literally one sent out, from the Greek *apostellein,* to send out) and in the Christian Church the title given to the 12 men whom Jesus selected to attend him during his ministry, witness his miracles, learn his doctrines, and thus be able to promulgate his religion. Their names were Simon Peter and Andrew his brother; James the greater, and John his brother, who were sons of Zebedee; Philip of Bethsaida; Bartholomew; Thomas; Matthew; James, the son of Alpheus, commonly called James the less; Lebbeus, his brother, who was surnamed Thaddeus, and was called Judas or Jude; Simon the Canaanite; and Judas Iscariot. Of this number Simon Peter, John, James the greater, and Andrew were fishermen; and Matthew a publican or tax-gatherer. When the apostles were reduced to 11 by the suicide of Judas, who had betrayed Christ, Matthias was chosen by lot on the proposition of St. Peter. Soon after, their number became 13 by the miraculous vocation of Saul, who, under the name of Paul, became one of the most zealous propagators of the Christian faith. The Bible gives the name of apostle to Barnabas also, who accompanied Paul on his missions (Acts xiv. 14), and Paul seems to give it to Andronicus and Junia, his relations and companions in prison. Generally, however, the name is used in the narrower sense to designate those whom Christ selected himself while on earth, and Paul, whom he afterward called. In a wider sense those preachers who first taught Christianity in heathen countries are frequently termed apostles: for example, St. Denis, the apostle of the Gauls; St. Boniface, the apostle of Germany; St. Augustine, the apostle of England; the Jesuit Francis Xavier, the apostle of the Indies; Adalbert of Prague, apostle of Prussia Proper. Tradition reports that several of the early apostles were married. The wife of St. Peter is said to have accompanied him on his journeys, and died a martyr. The tradition further states that St. Peter had a daughter Petronilla, who was also a martyr; this at least say St. Augustine, St. Epiphanius, and St. Clement of Alexandria. St. Philip also is said to have been married and to have had several daughters, among whom was St. Hermione. Hegesippus speaks of two martyrs, grandsons of St. Jude.

His wife was called Mary. St. Bartholomew is also said to have been married. Their history is largely a matter of tradition, save as it is recorded in the Acts of the Apostles.

Apostle of the Ardennes. See HUBERT, ST.

Apostle of the English. See AUGUSTINE, ST.

Apostle of Free Trade. See COBDEN, R.

Apostle of Germany. See BONIFACE, ST.

Apostle of Infidelity. See VOLTAIRE.

Apostle of Ireland. See SAINT PATRICK.

Apostle of Temperance. See MATHEW, T.

Apos'tle Spoons, a name applied to sets of spoons with handles formed of images of the Twelve Apostles and the Virgin.

Apostles' Creed. See CREED.

Apos'tles' Is'lands, or **The Twelve Apostles,** the name given to a group of 27 islands in Lake Superior, belonging to Wisconsin. The principal islands of the group are Ile au Chêne, Stockton, Bear, Madeline, and Outer. They have an area of 200 square miles. Brown sandstone is exported, and the islands are covered with a rich growth of timber. The cliffs have been worn into strange forms by the action of the waves. La Pointe, on Madeline Island, formerly the county-seat of Ashland County, Wisconsin, was settled by the French, who established Jesuit missions on the islands as early as 1680.

Apostle to the French. See DENIS, ST.

Apostle to the Indians. See ELIOT, JOHN.

Ap'ostol'ic Brethren, Apostolici, or **Apostolics,** the name given to certain sects who professed to imitate the manners and practice of the apostles. The last and most important of these was founded about 1260 by Gerhard Segarelli of Parma. They went barefooted, clothed in white, with long beard, disheveled hair, and bare heads, accompanied by women called spiritual sisters, begging, preaching, and singing, throughout Italy, Switzerland, and France; announced the coming of the kingdom of heaven and of purer times; denounced the papacy and its corrupt and worldly Church; and inculcated the complete renunciation of all worldly ties, of property, settled abode, marriage, etc. This society was formally abolished (1286) by Honorius IV. Segarelli was burned as a heretic in 1300. Another leader now appeared, Dolcino, a learned man of Milan. In self-defense they stationed themselves in fortified places whence they might resist attacks. After having devastated a large tract of country belonging to Milan they were subdued (1307) by the troops of Bishop Raynerius in their fortress Zebello, in Vercelli, and almost all destroyed. Dolcino was burned at Vercelli, 1 June 1307. The survivors afterward appeared in Lombardy and in the south of France as late as 1368.

Apostolic Church, the Church in the time of the apostles, constituted according to their design. The name is also given to the four churches of Rome, Alexandria, Antioch, and Jerusalem, and is claimed by the Roman Catholic Church and occasionally by the Episcopalians.

Apostolic Constitutions and Canons, a collection of regulations attributed to the apostles, but generally supposed to be spurious. They appeared in the 4th century, are divided into eight books, and consist of rules and precepts relating to the duty of Christians, and particularly to the ceremonies and discipline of the Church.

Apostolic Delegate, a permanent representative of the Pope in a foreign country. The term is sometimes confounded with the word ablegate, the latter meaning a temporary representative of the Pope for some special function.

Apostolic Fathers, the Christian writers who, during any part of their lives, were contemporary with the apostles. There are five: Clement, Barnabas, Hermas, Ignatius, Polycarp. Their writings are available in a recent collection made with great care by the able Biblical scholar, Bishop Lightfoot.

Apostolic Fathers, The: Revised Texts, with English Translations. By J. B. Lightfoot. A collection of about 12 of the earliest Christian writings, directly following those of the Apostles, made with great care and learning by the ablest of recent English Biblical scholars. The writings gathered into the volume represent those teachers of Christian doctrine who stand in the history nearest to the New Testament writers, and the account of them given by Dr. Lightfoot is not only the best for students, but is of great interest to the general reader.

Apostolic Majesty, a title granted by the Pope to the kings of Hungary, first conferred on St. Stephen, the founder of the royal line of Hungary, on account of what he accomplished in the spread of Christianity.

Apostolic Party, a name given to a body of Spanish fanatics who early in the 19th century clamored for the restoration of the Inquisition. About 1830 they became merged in the Carlist party.

Apostolic See, official title of the Pope, the Bishop of Rome, who, according to the doctrine of the Catholic Church, is the successor of Saint Peter.

Apostleship of Prayer, a pious association founded in France in 1844 by Rev. Francis Gautrelet for the purpose of advancing its members in the spiritual life and particularly of honoring the Sacred Heart of Jesus. There are three degrees of membership, composed of those who promise to make the morning offering of their thoughts, words, actions, and sufferings to God in union with the intention of Christ; those who recite once each day the Lord's Prayer and the Hail Mary ten times; and those who receive Holy Communion monthly as an act of reparation to the Sacred Heart of Jesus. The membership throughout the world is supposed to be about 30,000,000, and there are about 5,000,000 in the United States. The central office is at Saint Francis Xavier Church, New York.

Apostolic Succession. The doctrine of the direct and hierarchical succession from Christ's apostles. Its defenders maintain that the Christian ministry is a succession, that valid ordination is transmitted to the clergy only by accredited bishops who have received the power of ordination in direct line of succession from the apostles. The points of controversy are: (1) as to when and how the exclusive authority of ordination was given by Christ and the apostles; (2) by what act, if any, the transmission of this authority is to be made valid, (3) along what

lines has this supernatural commission come, and (4) whether or not this supernatural grace and spiritual authority are restricted to definite official lines of transmission. In later years differences have arisen among the Anglican scholars regarding these various points. Independents and Dissenters in England, of course, argue in favor of the theory that the Church itself as a body may constitute a legitimate ministry, with full powers of ordination, etc. This in general is the attitude of non-prelatical bodies. In defense of the doctrine see Gore, 'The Church and the Ministry' (1892); in opposition see John Brown, 'Apostolic Succession' (1898).

Edwin Knox Mitchell,
Hartford Theological Seminary.

Apos'trophe, a term in rhetoric indicating a figure of speech by which, according to Quintilian, a speaker turns from the rest of his audience to one person, and addresses him singly. Now, however, the signification is wider, including cases in which an impassioned orator addresses the absent, the dead, or even things inanimate.

The name is also employed in grammar to denote the substitution of a mark like this (') for one or more letters omitted from a word, as *tho'* for *though, 'twas* for *it was, king's* for *kinges.* It is also applied to the mark indicating such substitution, especially in the case of the possessive. The old possessive singular was *es,* and the apostrophe stands for the omitted *e.*

Apotheo'sis, a Greek term indicating the ceremony by which a man was raised to the rank of the gods. The custom of placing mortals, who had rendered their countrymen important services, among the gods was very ancient among the Greeks, who generally followed in so doing the advice of an oracle. On their coins most of the founders of cities and colonies are immortalized as gods; and in subsequent times living princes assumed this title. The Romans for several centuries deified none but Romulus, and first initiated the Greeks in the fashion of frequent apotheosis after the time of Cæsar.

Appalachian America, a term first used by the present writer in 1893, now generally accepted to designate the mountain region of the southern United States. This territory has a certain sociological unity, based on physical conditions, which was long obscured by the fact that it was parceled out among several different States.

Physiographically it is a mountainous territory without arms of the sea, inland lakes or other natural waterways. And furthermore it is a territory which forbids canals, and has not yet been opened up by railroads or even turnpikes. Its universal characteristics are difficulty of communication, isolation, and remoteness. These conditions were less severe, and were largely overcome by greater commercial and intellectual activity in the portions of the Appalachian system which lay in the northern free States. Accordingly as a sociological grand division Appalachian America begins with the southern boundary of Pennsylvania and the Ohio River, and embraces the mountainous portions of the Virginias and Carolinas, Kentucky and Tennessee, Georgia and Alabama. In this vast area, which is all a land of saddles and bad roads, there are, of course, great varieties of elevation and climate, from the "dissected plateaus" of Kentucky to "the land of the sky" in North Carolina. Descriptions of the geological formations, mineral, forest, and other resources, and physiographic conditions, will appear under the several States. But the one great fact about the whole territory is that it condemns its inhabitants to the ills of isolation.

Historically, Appalachian America received its first sparse settlements about the time of the Revolutionary War. A great tide of migration passed through it and around it to the West, and the valley land was occupied by hardy settlers. It was these who fought the battle of King's Mountain, and in the war of 1812 riflemen from the mountains gave material assistance in defeating the British at New Orleans. When the slave power developed in the South subsequent to the Revolution, Appalachian America, retaining its revolutionary spirit of liberty, came to be looked upon with hostility by its Southern neighbors. Slavery was never common in the mountains, and the scorn of the slaveholders for those who did not hold slaves was heartily returned by the mountaineers. Thus social barriers were added to the barriers of nature and the mountain people still further isolated from the world. In the Civil War, however, they emerged from their obscurity and surprised both the North and the South by their vigorous and effective stand for "union and liberty." They held Kentucky in the union, made West Virginia "secede from secession," well-nigh divided Tennessee, and furnished recruits to the loyal armies even from Alabama and South Carolina. Many of these recruits were not enrolled as coming from these States, but the regular regiments enlisted from slave States, nearly all from the mountains, aggregated about 200,000 men. The sufferings of the loyal people throughout the mountains, and especially in East Tennessee, and the eloquence of "Parson Brownlow," for the time fixed the attention of the nation. Naturally the mountaineers have since the War followed the fortunes of the Republican party.

Sociologically Appalachian America reveals most interesting survivals of the spirit, arts and conditions of colonial times. Within its area are many valleys and villages which differ from other parts of the United States only in superficial matters like the greater number of saddle horses and the more free hospitality. But there is an immense population (commonly estimated at 2,000,000) which has been little affected by modern ideas. The stock is mainly British, representing rural England and the Scotch-Irish, though with traces of the Huguenot and the German. A large number of Washington's soldiers settled in the valley land of Appalachian America, and there is no evidence that the pioneers of the mountain region were in any way inferior to the first settlers in the more favored "blue grass sections." The early settlers had the education of their time, which lessened in succeeding generations. The conditions of life grew harder when the valley land and game were exhausted, and the public school did not come in until the "reconstruction period." As a result, a great part of all the native born illiterates in the United States — many of them people of good character and good abilities — are in this region. In some counties the

illiterate white voters exceed a third of the whole number. It is among these people that we find a survival of pioneer conditions — the woodcraft, the log cabin, the open fireplace — with a noble stone chimney in Kentucky, degenerating into a stick and mud chimney farther south. The arts of spinning, dyeing, and weaving are still found, together with a wealth of Saxon speech, and even old British ballads which have come down by oral tradition. Survivals in language consist of ancient pronunciations and constructions, and the persistence of words and meanings elsewhere obsolete; as "pack" for carry, "gorm" meaning to muss, etc. A kind of minstrelsy still exists among the ruder classes, so that we may find drinking songs and folk-lore still in the making. Preachers are few and poorly paid, and religion is of a mediæval and fatalistic type. The feuds and homicides which attract so much attention belong with these other survivals. Weapons are carried to some extent in all parts of the South, because men retain the Elizabethan idea that while the government protects the land from foreign foes, each man is to protect his private honor and interests with his own right arm. In the mountains this view is more plausible because the law is not always carried out with the certainty and majesty which could inspire either confidence or dread. Considering these adverse conditions of life, the general good order and morality of the mountains is very creditable. A woman or a stranger who behaves properly is always safe. The chief disorders arise from corrupt political leaders and the whiskey bottle, and the mountain people have taken the first great step of progress in very generally enacting local option laws which prohibit the sale of intoxicants. Yet the "moonshine still" — the secret manufacture of spirits on which no tax is paid — survives in many places, and makes Christmas or election time a terror to the mothers of mountain boys.

A most striking characteristic is the absence of any foreign element in the population. The 35 mountain counties of Kentucky, for example, contain 478,205 people, with only 2,120 who are of foreign birth, and these massed in a few counties where mines or lumber interests have been recently established. There are 15 counties each containing less than ten persons of foreign birth. The massing of so great a population of purely American birth and breeding is very significant. And these people who owned land but did not own slaves (never to be confused with the "poor whites") constitute the true yeomanry of the South, its best nucleus for a true middle class. Large families are the rule, and the standard of physical development is high. With this large birth-rate the mountain region is approaching the limit of population and must either improve the means of subsistence, or emigrate. Both movements have begun. In time the mineral wealth will bring railroads to some extent, and if proper educational guidance is furnished Appalachian America will become what Scotland is in Great Britain, a storehouse of national vigor and patriotism.

Printed information regarding Appalachian America is fragmentary and partial. Chas. Dudley Warner reported a charming tour 'On Horseback Through Virginia' and important notices occur in Fisk's 'Old Virginia and her Neighbors,' Roosevelt's 'Winning of the West,' and Draper's 'King's Mountain and its Heroes.' The spirit of war times is reproduced in Barton's 'Hero in Homespun,' and the general characteristics of mountain life appear in the tales of John Fox, Jr., and Miss Murfree ("Charles Egbert Craddock"). See also articles in 'New England Magazine' (March '97), 'Atlantic Monthly' (March '99), 'Review of Reviews' (March 1900), and files of the 'Berea Quarterly.'

W. G. Frost,
President Berea College.

Appalachian Mountain Club, the name of an organization interested in the exploration and study of the mountain ranges of eastern North America, and the preservation of their woodlands, waters, and historic sites for the use of the public. The club publishes a journal, called 'Appalachia,' now in its 10th volume (1903).

Appalachian Mountains, the great mountain system of the eastern United States extending from southeastern New York to northern Alabama. It includes a number of ranges and mountain groups of which the most important are the Alleghanies, the Blue Ridge, the Cumberland Mountains, and the Black mountains. The Catskills form really the northern termination, although the system is commonly extended so as to include the Green Mountains, the White Mountains, and the line of elevations extending northward of the Gulf of St. Lawrence. The extreme length of the system is about 1,300 miles, and its greatest width over 100 miles. The most remarkable feature of the general formation of the Appalachians is the regular arrangement of its ridges and valleys, these being, in general, parallel to the Atlantic coast line. This arrangement is particularly noticeable in the central part of the system, through Pennsylvania and Virginia. In general the ridges lie along two parallel lines from 50 to 100 miles apart, thus enclosing a longitudinal valley whose sides rise rather abruptly over culminating points of the mountains. This great central valley extends from New York to the southern end of the system, including the Cumberland valley in Pennsylvania and the great valley of Virginia and of Tennessee. This region is very fertile throughout its whole length, and is especially well cultivated in Lancaster, Berks, and Lehigh counties, Pennsylvania. The Appalachians show no remarkable elevations, and the height of the summits appears less than it really is, because the mountains rise from a plateau varying from 500 feet in Pennsylvania to 1,500 and 2,000 feet in Virginia and Tennessee. The lowest peaks are found in Pennsylvania, none rising much above 2,000 feet. The culminating point of the whole system is Mount Mitchell, in the Black Mountains (6,711 feet): others of the high peaks are also found in the Black Mountain range, Balsam Cone 6,671 feet, Black Brother 6,619, and Mount Hallback; the Smoky Mountains, too, include some high peaks, Clingmann Dome 6,619, Guyot 6,636, Mount Alexander 6,447, Mount Seconte 6,612, and Mount Curtis 6,568. The culminating point of the northern part of the system is Mount Washington, New Hampshire (6,233 feet). The peaks are generally of rounded outline and lack the bold picturesqueness that characterizes the

Rocky Mountains and other ranges in the western United States. Their low altitude and smooth contour are the result of the long-continued erosion which has removed great thicknesses of strata since the first uplift.

Geology.— The Appalachians show all geological formations from the metamorphic group to the so-called coal-measures, the latter including sandstones, shales, limestones, and coal. The strata of the western slope with their regular horizontal arrangement show a great contrast to the disturbed stratification of the eastern slope. There the rock formations are con fused and pressed into folds and wrinkles with an inclination generally southeast. The strata of the system are all of marine or terrestrial origin, the latest being those of the coal formation. After the formation of these strata the mountains were elevated to their present position by a force that proceeded from the southeast, working probably by many successive impulses; and the receding waters hollowed the gaps through the ridges so characteristic of the Appalachian topography, and gave the mountains their present conformation. The chief minerals of the Appalachians are iron and coal. Iron ores, magnetite, hematite, and limonite, are very abundant; the magnetic iron is found especially in what is called the Champlain Iron District. The hematite and limonite ores are found all along the great Appalachian valley and are of great commercial importance; while the earthy carbonite of iron found in many parts has been largely manufactured. Coal is perhaps the most important product; the coal deposits of the Appalachians include the whole anthracite field of Pennsylvania and New York with an area of 400 to 500 square miles, and the bituminous fields of Pennsylvania and other States, with an area of 56,000 square miles. Gold, silver, copper, and lead are found in comparatively small quantities and are of little importance commercially, but the deposits of marble, limestone, fire-clay, gypsum, and salt are abundant and valuable.

Drainage.— The Appalachians form the watershed between the Atlantic Ocean and the Mississippi River systems; this does not lie in one continuous line, but shifts its position from one line of ridges to another, so that many of the rivers cut their way through the mountains from west to east, or east to west; the Delaware and Susquehanna, for example, with their branches. These two rivers, with the Potomac and James, drain the most of the eastern slope; the Ohio, with its tributaries, is the chief means of drainage on the western slope.

Flora and Fauna.— The mountain slopes are heavily wooded throughout the whole system. The white pine is found in all portions; the sugar maple, the white birch, ash, and beech grow on the northern mountains; the oak, cherry, white poplar, white and yellow pine farther south. On the poorer lands the evergreens flourish, such as spruce, hemlock, evergreen, and balsam-fir, which, on account of their dark foliage covering the summits of the Black Mountains, have given this range its name. There are large quantities of flowering shrubs, particularly the rhododendrons, azaleas, and laurel often growing in almost impenetrable thickets, and many varieties of smaller plants and flowers. Panthers and wolves have practically disappeared from the mountains, but bears, deer, and wild-cats are quite common. Small game birds are plentiful, and wild turkeys also on the southern ranges. Rattlesnakes and copperheads are found in all parts of the Appalachians, but not in great numbers.

Apparent, a term employed by mathematicians and astronomers to denote things as they appear to the eye in distinction from what they really are. Thus they speak of apparent motion, magnitude, distance, height, time, etc. So important is this difference between reality and appearance, particularly in regard to the heavenly bodies, that we find all early astronomers, who were ignorant of this fact, running continually into error; and a great advancement in science was required before mankind was able to establish systems opposed to appearances. Every one knows that a body may appear to move while it is, in fact, at rest, and the motion is in the spectator, or the place on which he stands, as is the case with the sun in relation to the inhabitants of this earth. The apparent altitude of a heavenly body is what appears to be its angle of elevation above a horizon which may itself be apparent — that is, the seeming junction of sea and sky; or "sensible" — that is, a plane passing through the point of observation at right angles to the plumb-line; or true — that is, a plane parallel to the "sensible" horizon and passing through the centre of the earth. When the altitude of a heavenly body is measured corrections are made for refraction, parallax, and, if the measurement is from a visible sea horizon, for the height of the observer above the water.

The phrase heir apparent signifies one whose right of inheritance is indefeasible provided he survive his ancestor; as the eldest son or his issue, who must, by the course of the common law, be heirs to the father. Heirs presumptive are those who, if the ancestor should die immediately, would in the existing state of things be his heirs.

Ap'pari'tion, the name given to an illusion involuntarily generated, by means of which forms not present to the actual sense are depictured with intensity sufficient to create a temporary belief in their reality. It is now generally held to be the result of the reaction of an excited imagination, renovating past feeling or impressions, with an energy proportioned to the degree of excitement. But although the illusion thus generated is necessarily co-existent with the state of excitement in which it has its origin, or, in other words, ceases to be active when the phenomena vanish, it does not therefore follow that the mind, when it regains its ordinary condition, becomes immediately sensible of the hallucination under which it has for a time been laboring, or capable of

distinguishing between perceptions of sense and phantasms of imagination. On the contrary, observation proves what theory equally sanctions, that the conviction of reality generally outlasts the impressions which originally produced it; and that, so far from any suspicion of illusion being entertained, or any power of discriminating the actual from the imaginary being evinced, this conviction takes entire possession of the mind, in many instances maintaining its hold with a firmness which all the force of argument and reason is insufficient to overcome. Hence the tenacity, and, we may add, the universality of the belief in apparitions; and hence also the prodigious diversity of forms under which these spectral illusions are presented in the popular legends and superstitions — a diversity, in fact, which seems commensurate with the incredible variety of influences, whether morbific or other, by which the imagination may be excited, and past feelings or impressions vividly renovated in consequence of its reaction on the organs of sense. Sir D. Brewster has remarked as a physical fact that «when the eye is not exposed to the impressions of external objects, or when it is insensible to these objects, in consequence of being engrossed with its own operations, any object of mental contemplation, which has either been called up by the memory or created by the imagination, will be seen as distinctly as if it had been formed from the vision of a real object. In examining these mental impressions,» he adds, «I have found that they follow the motions of the eyeball exactly like the spectral impressions of luminous objects, and that they resemble them also in their apparent immobility when the eyeball is displaced by an external force. If this result shall be found generally true by others it will follow that the objects of mental contemplation may be seen as distinctly as external objects, and will occupy the same local position in the axis of vision as if they had been formed by the agency of light.» This goes to the very root of the theory of apparitions, all the phenomena of which seem to depend upon the relative intensities of the two classes of impressions, and upon the manner of their accidental combination. In perfect health the mind not only possesses a control over its powers, but the impressions of external objects alone occupy its attention, and the play of imagination is consequently checked, except in sleep, when its operations are relatively more feeble. But in the unhealthy state of the mind, when its attention is partly withdrawn from the contemplation of external objects, the impressions of its own creation, or rather reproduction, will either overpower or combine themselves with the impressions of external objects, and thus generate illusions which in the one case appear alone, while in the other they are seen projected among those external objects to which the eyeball is directed, in the manner explained by Sir D. Brewster. It may be added that the reasoning applied to the impressions derived from the sense of sight is equally applicable to those received through the medium of any other sense,— as the ear, for instance, an organ which ministers abundantly to the production of spectral illusions. This theory explains only those apparitions known to be subjective illusions, but it does not account for those objective apparitions, of which there are many and well authenticated accounts. Modern science has explained some of the objective apparations.

Appeal', a legal term signifying the removal of a cause from an inferior tribunal to a superior, in order that the latter may revise, and, if needful, reverse or amend, the decision of the former.

In the United States the distinction between an appeal, which originated in the civil law, and a writ of error, which is of common law origin, is that the former carries the whole case for review by the higher court, including both the facts and the law; while the latter removes only questions of law. An act of Congress of 1875 provides that the judgments and decrees of the circuit courts of the United States shall not be re-examined in the supreme court unless the matter in dispute shall exceed the sum or value of $5,000, exclusive of costs. No judgment, decree, or order of a circuit or district court, in any civil action at law or in equity, shall be reviewed in the supreme court on writ of error or appeal unless the writ of error is brought or the appeal is taken within two years after the entry of such judgment, decree, or order; save in the case of infants, insane persons, and imprisoned persons, when the period is two years exclusive of this term of disability. An appeal from a district court to a circuit court of the United States must be taken within one year. An appeal from the district court in admiralty to the circuit court must be made immediately after the decree, in open court, before the adjournment *sine die;* and should be taken to the next succeeding circuit court. An appeal may be taken from the State courts to the supreme court of the United States, in cases involving the validity of a treaty or statute of, or authorized under, the United States; on the ground of repugnance to the Constitution, etc.

The effect of an appeal is generally to annul the judgment of the lower court so far that no action can be taken upon it until after the final decision of the cause. In many States, before the judgment of an inferior court will be reversed on the ground of error, the appellant, as the party taking the appeal is called, must show to the court that substantial injustice has been done him. In other States courts have held that when an error is shown to have been committed it will be presumed to have been prejudicial to the complaining party, and the judgment will be reversed unless the respondent shows that the error was harmless. Appellate courts, however, will not reverse the judgments of trial courts for technical or other errors where it appears from the record itself that the errors complained of were not prejudicial to the appellant.

In legislation an appeal is the act by which a member of a legislative body who questions the correctness of a decision of the presiding officer, or «chair,» procures a vote of the body upon the decision. In the House of Representatives of the United States the question on an appeal is put to the House in this form: «Shall the decision of the chair stand as the judgment of the whole House?» If the appeal relate to an alleged breach of decorum, or violation of the rules of order, the question is taken without debate. If it relate to the admissibility or

relevancy of a proposition, debate is permitted, except when a motion for the previous question is pending.

Appear'ance, a legal term implying the coming into court as a party to a suit or action, whether as plaintiff or defendant. On the part of the plaintiff no formality is required. The appearance of the defendant may be effected by making certain formal entries in the proper office of the court, expressing his appearance, or in case of arrest is effected by giving bail, or by putting in an answer or a demurrer.

Appen'dici'tis, the name applied to an infectious disease of the vermiform appendix, a small organ occupying the lower right side of the abdominal cavity. The first authentic record of the distinct localization of a lesion in the appendix was by Saracenus in a letter dated 28 Aug. 1642. A number of observers described the disease in later years, but it is to the honor and credit of American medicine that Reginald Fitz of Boston wrote his epoch-making memoir in 1886, 'On Perforative Inflammation of the Vermiform Appendix.' Two years later Fitz advanced the sound theory that the diseases variously described as typhlitis, peri-typhlitis, para-typhlitis, appendicular peritonitis, and peri-typhlitic abscess were all varieties of one and the same affection: namely, appendicitis. Rapid strides have been made during the last decade in the study of the disease, and mainly through the exertions of American surgeons the treatment of appendicitis has been placed upon a sound and rational basis. In the embryologic development of the human intestinal tract there is at first a straight tube, divided into the foregut, midgut, and hindgut, each of which gives rise to different structures. From the midgut a diverticulum or pouch appears which marks the dividing line between the large and small intestine. This pouch becomes larger and is called the cecum, but its terminal portion does not keep pace with the growth of the base and remains as a small projection depending from the cecum. This is the appendix vermiformis; it has no function and merely serves as a constant source of menace from its liability to disease.

During early intra-uterine life the appendix lies near the umbilicus (navel), but about the sixth month descends into the right iliac fossa. If two lines are drawn at right angles to each other, intersecting at the umbilicus, the abdomen will be divided into four quadrants. The lower right quadrant will include the right iliac fossa, and in the majority of cases the appendix. The base of this organ will usually be found at a point two inches from the umbilicus on a line drawn from the latter to the anterior superior spine of the iliac bone and known as McBurney's point.

The appendix is held in place by a fold of peritoneum called the meso-appendix, through which a single artery runs to supply the needed nutrition. The meso-appendix is derived from the lower layer of the mesentery, the fold of peritoneum which suspends the small intestine. In women there is usually, in addition, another blood-vessel which comes up to the appendix from the ovary. The end of the appendix is free and may point in any direction. This fact explains the great diversity of the symptoms often noted in appendicitis.

Bearing in mind, then, that the appendix is without a function, hangs in a dependent position from a portion of bowel always containing irritating material, and has a very poor blood supply, it can readily be understood why this organ is so often attacked by disease. It hangs in a cavity lined by peritoneum, a delicate membrane covering the inner surface of the abdomen and the exterior of the intestines, which easily absorbs poisons, transmitting them to the whole body. Inflammation of this membrane is known as peritonitis, a very fatal disease, and one often caused by appendicitis. Many deaths supposed to be due to peritonitis pure and simple are really caused by appendicitis. The intestines at all times are loaded with germs which under favorable conditions may be converted into deadly little organisms. These microbes attack the inner coat of the appendix, destroy it with the formation of pus, and may ulcerate through all the walls of the appendix causing an abscess with peritonitis. But for such a sequence of events to occur certain other factors are necessary. The old idea that foreign bodies, such as grape-seeds, are the cause of the disease, is now known not to be true. While foreign bodies are frequently found in the appendix, in rare instances only they are seeds, etc., but are almost always found to be hard masses of fecal material which has entered the appendix while soft, become dry and hard, forming a fecal concretion (*fecal calculus*). By exerting pressure on the wall of the appendix these hard bodies may aid in the production of the disease. In rare instances pins have found their way into the lumen of the appendix and induced appendicitis. It is interesting in this connection to note that worms are frequently discovered in the appendix. The *Oxyuris vermicularis*, or seatworm, has been found in large numbers, completely filling the appendix, and the *Ascaris lumbricoides*, or roundworm, has sometimes occupied this organ. In studying the etiology of appendicitis we find the young are more frequently attacked than the old, the disease occurring less commonly in those over 50 years of age. It is fortunate that such is the case, because older people do not stand operations as well as those in early adult life. Their resistance to shock is less, and the liability to kidney breakdown and to pneumonia would result fatally in many instances. The greater susceptibility of young adults to appendicitis is due to the numerous disturbances of their gastro-intestinal tracts from dietary indiscretions, and, secondly, to the proneness to inflammation of the adenoid (glandular) tissues throughout the body during adolescence. Analogy is found in the predominance of lesions of the tonsils and of the glands in the neck and mesentery during the period of development. In children appendicitis is characterized by the intensity of the lesion and by the remarkable recuperative power which children have. About two thirds of all cases of appendicitis occur in males. The reason for such a disparity is to be found in several facts. Females are less exposed to inclemencies of the weather and other deleterious influences, they undergo less muscular exertion, and their appendixes in the majority of instances have a better blood supply. Of diseases that predispose to appendicitis may be mentioned constipation, gastro-enteritis,

dysentery, typhoid fever, influenza, etc. Constipation exerts an influence by causing sluggishness of the bowels, resulting in poor drainage of the appendix. Noxious materials may be retained and favor an increase in the virulence of bacteria, especially the *Bacillus coli-communis*. Gastro-enteritis, or inflammation of the stomach and intestines, is a very important factor in appendicitis. In this disease the cecum may become inflamed and by extension involve the appendix. In many instances such is the mildness of the alterations in the walls of the appendix that they do not engender any clinical manifestations. At times, however, the lining membrane of the appendix is directly attacked, and acute appendicitis may supervene. Under other circumstances catarrhal changes of mild degree persist and lead to chronic appendicitis. Dysentery and typhoid fever are more remote causes of appendicitis. They cause catarrhal alterations, swelling, congestion, and œdema of the adenoid (glandular) follicles of the organ. Not uncommonly ulcerations occur, and the resulting scar is one of the most important factors in the subsequent development of appendicitis by causing a stricture in the lumen of the appendix, obstructing the drainage of the organ, thereby favoring the retention of irritating material. Influenza exerts an influence from the intestinal lesions to which it gives rise.

The most important predisposing cause of appendicitis is the fact that the appendix has already been the seat of one or more attacks of the same affection. The seemingly greater number of cases of appendicitis observed in recent years is not that the disease has been on the increase, but rather that a greater refinement in diagnosis has rendered physicians more skilful in pronouncing the true nature of the malady, which in former years was variously styled inflammation of the bowels, peritonitis, gastritis, obstruction of the bowels, etc. The factors that operate to render the appendix less resistant than other portions of the intestinal tract to the onslaught of bacteria and other determining causes are several. The blood supply becomes defective because of the liability to partial or complete obstruction of the blood channels as a result of kinking, twisting (*volvulus*), or external bands of adhesions, etc., secondary to primary inflammation of the appendix. Disturbances of circulation, and hence of nutrition, are also produced by active and sometimes ineffectual muscular efforts of the appendix to rid itself of fecal concretions or even inspissated fecal matter. Defective drainage, which has been referred to, is of great importance in the pathogenesis of appendicitis because of the anatomical and physiological peculiarities of this organ. The average length of the appendix is about 8 to 9 cm. (3½ inches), while the diameter is only 3 mm. to 5 mm. (⅛ to ⅕ inch). Therefore in such a long narrow tube free drainage is not favored. The peritoneal covering forms what is known as the meso-appendix in such a manner as to draw the appendix into a curve and thus aid in any angulation resulting from disease. As additional factors of importance are the relatively large extent of mucous membrane presented by the appendix and the large amount of lymphoid (glandular) tissue, not only in the neighborhood of the valve-like opening into the cecum, known as Gerlach's valve, but also scattered through the wall of the appendix. The latter is of especial significance in view of the proneness of adenoid tissue throughout the body to inflammation when subject to even slight irritation by bacteria and their poisons. An analogous condition may be observed in the tonsil, which is so frequently invaded by bacteria with a resulting tonsilitis (quinsy). Owing to this similarity the appendix has frequently been called the «abdominal tonsil.» In considering the symptomatology of the two forms of appendicitis — the acute and the chronic — it must be borne in mind that it is not always possible to determine the extent of disease which has actually taken place in the appendix from the clinical manifestations. While it is true that, in general, the clinical symptoms become more marked with the increase in the severity of the appendicular and peritoneal lesions,— that is, when perforation, abscess, or gangrene supervene,— it is also a fact that remission of all symptoms may occur, and yet the disease be progressing to a fatal termination. It is likewise a fact that the symptoms suggestive of perforation of the appendix with abscess formation in one patient, may arise in another patient in consequence of the development of an abscess without perforation of the organ. It is better therefore to consider acute appendicitis as a clinical entity. Similar reasoning obtains with regard to chronic appendicitis, although in the latter the questions requiring solution are less complicated.

Acute Appendicitis.— There are three symptoms of acute appendicitis so constant and, when associated, so characteristic of the disease that they are designated the «three cardinal symptoms.» These are pain, tenderness, and rigidity of the right lower quadrant of the abdominal wall. Pain is the initial symptom and usually develops suddenly in an individual previously well. At the onset of the affection the pain is paroxysmal or colicky in character, coming in storms with intervals of rest, in which respect it simulates an attack of acute indigestion. The location is at first centered about the umbilicus, or the pit of the stomach, later becomes diffused all over the abdomen, and finally becomes localized to the right iliac fossa. In recurring cases the initial pain of the later attacks is often referred immediately to the right iliac fossa. The pain of appendicitis may, however, be referred to any region of the abdomen. It is a lack of knowledge of this fact that has lead to many errors of diagnosis in acute abdominal affections. The location of the pain depends to a great extent upon the position and direction of the appendix. For instance, with an appendix lying behind the cecum and pointing upward until its tip nearly reaches the gall-bladder, symptoms are produced resembling very closely those induced by affections of the latter organ. In other cases pain is felt upon the left side of the abdomen and denotes that the appendix occupies a left-sided position or that it hangs into the pelvis. These examples will draw attention to the statement that the pain in appendicitis will depend upon the direction and position of the appendix. Tenderness upon pressure is one of the most valuable and constant signs of appendicitis. It is always present, but, unlike the subjective symptom, pain,

is limited first to the site and position of the appendix. To elicit this symptom the pressure should be made in as light and delicate a manner as possible. The open hand should be laid over the tender area and the fingers gently depressed, ceasing as soon as the patient complains of pain. It should be remembered that the appendix may be distended with pus and on the verge of rupture, and any undue roughness in palpation might endanger the life of the patient. A celebrated German surgeon has truly said that «many a doctor who has sufficient practice and experience nevertheless never learns to palpate, since lightness of hand is wanting in him.» It is a good plan to begin to palpate over on the left side away from the seat of pain, and gradually approach that region. As complications arise the point of tenderness may vary; for instance, in those cases previously referred to where the appendix occupies a pelvic position, the point of greatest tenderness will usually be found to the left of the median line. In such a location of the appendix where the disease has advanced to a stage when an abscess has formed in the pelvis, a vaginal or rectal examination detects a point of resistance on the right side with more or less marked tenderness. The third cardinal symptom is rigidity of the right side of the abdomen and particularly of the rectus and other abdominal muscles. It is the most constant symptom of the three and appears shortly after the onset of the attack. It varies in degree in different cases, but is generally well marked, and is most intense over the site of the inflamed appendix. The variation observed ranges from rigidity so slight as to be barely appreciable up to a condition absolutely precluding any palpation, and to which the term «board-like» rigidity is applied. The degree of rigidity is usually in direct proportion to the severity of the lesion, but not invariably so. When the peritoneal cavity becomes involved with the development of peritonitis the entire abdomen becomes rigid and board-like, followed by distension or tympany from paralysis of the intestines. While the three cardinal symptoms are the most important indications of acute appendicitis there are other clinical manifestations that are more or less constantly present and are of value in aiding in the formation of a diagnosis. Of these there should be noted disturbances of the gastro-intestinal tract (nausea and vomiting, etc.), elevation of the temperature, increased pulse and respiration rate, changes in the urine, etc. Nausea is a nearly constant symptom in appendicitis and usually coincides with the initial pain; it may be followed by vomiting, which at first consists of the gastric contents, then of bile or bile-stained fluid, and finally, if septic peritonitis develops, of the contents of the intestines. Such a condition, when not seen early, has frequently been mistaken by the family physician for intestinal obstruction.

In cases of appendicitis which progress rather rapidly to peritonitis, with the marked nausea and vomiting characteristic of such a condition, the pain suffered is apt to be severe. The attending physician, often following the promptings of the patient, administers the too-convenient hypodermic of morphine, relieving the patient, but at the same time masking the symptoms and rendering the task of the surgeon called in for consultation an exceedingly difficult one. The giving of morphine for the relief of pain in appendicitis is a pernicious habit. Nausea and vomiting rarely persist after the pain has become localized to the right iliac fossa, though in some unfavorable cases vomiting may be continuous and uncontrollable. The condition of the bowels previous to the attack of appendicitis is very variable. In the majority of cases constipation is observed, and such sluggishness may be directly traceable as an etiologic factor of some importance. But there are many cases where diarrhœa ushers in the attack, and in other instances it may alternate with constipation. Fever must not be relied upon as a diagnostic sign, as it bears no direct relation to the gravity of the anatomical lesions. While upon the onset of the disease the temperature usually rises to 101° and 102° F., it may return to normal again despite the advance of severe complications such as perforation or gangrene of the appendix. Coincident with the development of an abscess around the appendix there is usually a rise of temperature, but again in this instance such a rise is not constant. There are, finally, some cases in which the temperature continues high from the commencement to the termination of the attack, and yet the patient makes an easy recovery. The amount of fever should therefore be considered as the expression of the reaction and resistance of the individual to infection. The condition of the pulse is a more constant aid than the degree of temperature, and in this instance the quality is of more importance than the rate of speed. If the pulse is strong, of good volume, regular, and the rate proportionate to the temperature, the outlook is favorable, and *vice versa*. Variations in the respiration are not of much importance. The breathing is embarrassed in toxic states, from the distension of peritonitis, and sometimes owing to the pain induced the patient will favor the use of the chest muscles entirely. A quite characteristic position often assumed by the patient is with the right leg and thigh flexed, while the left leg remains prone and the patient demands perfect quiet. In addition there may be perspiration, a furred tongue, and a slight expression of anxiety appear upon the features. The patient will frequently complain of rectal and vesical (bladder) irritability when the appendix occupies the pelvic position. An increased frequency in urination is the usual symptom, yet there may be inability to void the urine. The symptoms which have been described are typical of the usual attack of acute appendicitis, though marked variations may occur, depending upon the position of the appendix or the presence of adhesions from former attacks. With the history of previous more or less severe attacks of abdominal colic and not necessarily referred to the appendix, a patient previously well is suddenly seized with severe pain, usually throughout the abdomen. Nausea follows and sometimes vomiting. The pain soon becomes more intense over the site of the appendix, and in a few hours this locality alone is involved. If the patient should be so fortunate as to send for his physician at this time, namely, within 24 hours of the attack, and if operation is advised and performed, recovery is practically assured. But unfortunately this is not always the treat-

ment pursued. The disease is in its earliest stages, with the inflammatory lesion confined to the appendix, and the particular sequence of events which will follow in any individual case cannot be foretold. In some cases the appendix under the influence of rest is able to eliminate the noxious materials causing the inflammatory lesions, recover its vitality, and apparently become in as good condition as before the attack: but lymphoid (glandular) tissue which has once been the seat of infection is exceedingly prone to future attacks. In still other cases the disease extends through the wall of the appendix and induces a mild peritonitis localized to the coils of intestines and tissues immediately contiguous to the appendix. With the appearance of infecting bacteria or of their poisons in the peritoneal cavity, this membrane throws out a thin fluid or serum and an exudate (lymph) which organizes into firm tissue, known as adhesions. These adhesions glue the coils of intestine surrounding the appendix together, they cause adherence of such intestines to the roof of the cavity, which is the abdominal wall, and with the aid of the omentum, a fatty apron-shaped body covering the intestines, a firm wall is formed about a cavity containing the appendix, preventing the escape of toxic materials into the general peritoneal cavity. Should the disease, under medical treatment, subside, the lymphatics and the white blood corpuscles speedily destroy the infectious material, but the adhesions too often remain and cause constant irritation. In time a period of chronicity is reached when any unusual exertion provokes a dull ache in the lower right quadrant of the abdomen. The digestion is impaired, and the bowels become sluggish in their movements from the dragging of the adhesions upon the valve between the large and small intestines. In women, the subject of chronic appendicitis with involvement of the ovary and fallopian tube on the right side, slight attacks of appendiceal colic will occur during each menstrual period, and all treatment directed against dysmenorrhœa will prove unavailing. The appendix in such cases may become obliterated into a mere fibrous cord, or, as more commonly occurs, occlusion takes place at the opening into the cecum or at the site of a stricture, and the appendix becomes distended with clear mucus. While operations upon chronic forms of appendicitis in the presence of adhesions are attended with but little risk, yet the operation itself is more tedious and the incision longer than when operation is performed in the early stages of the disease. Having dealt with the favorable terminations of acute appendicitis, there remains that far too numerous class of cases where the appendix perforates, with abscess formation and sometimes general peritonitis. If the infection of the appendix is severe enough, its walls may become gangrenous and break down with a perforation occurring into the peritoneal cavity. In this case the peritoneum usually becomes infected in advance of the perforation and enough time is gained for the formation of adhesions such as have been described. In what is known as fulminating appendicitis the progress of the disease is so rapid that no adhesions are formed, and in 24 hours or less after the onset of the initial symptoms the patient may be suffering from a violent general peritonitis. But, as a rule, the escape of purulent material through a perforation in the appendix occurs into a preformed cavity, the walls of which consist of the abdominal wall, the iliac fossa, cecum and matted coils of small bowel, and the infiltrated omentum. This cavity becomes filled with pus and a true appendiceal or peri-typhlitic abscess is formed. The amount of pus varies from a teaspoonful to a pint, or in extreme cases even more. With the formation of the abscess the symptoms change somewhat. The severe pain of the early inflammatory stage becomes more dull and sometimes is referred to the back or left side, tenderness is increased, while the rigidity is more marked. The tongue becomes coated and the breath foul, chills are rarely observed even in the presence of pus, and when present — especially a single, severe chill ushering in an attack — usually mean a gangrenous condition of the appendix. There is fever, increased pulse-rate, and the patient shows the effect of absorption of poisonous products into his general circulation. An examination of the blood shows an increased number of the white blood corpuscles (leucocytosis). Palpation of the abdomen will reveal a mass in the right iliac fossa, rounded, hard, and often tender. The patient may not complain of any pain beyond the dull ache referred to, though the act of coughing or taking a deep breath usually results in an exacerbation of pain. In some cases with an appendix deep in the abdomen and behind the cecum, an abscess can exist which cannot be palpated. When such a condition is suspected it is not safe to prod the abdomen too hard for fear of rupturing the abscess. If the pus extends into the pelvis there are the additional symptoms of vesical and rectal irritability, and a vaginal or rectal examination detects a bulging area extremely tender to the examining finger. In women and girls the effect of such a pelvic abscess is frequently disastrous. The open ends of the fallopian tubes become bathed with the pus, and either a salpingitis or occlusion of the tubes takes place. The tubes are thereby prevented from fulfilling their function of transmitting the ova to the uterus, and sterility may result. The extension of the pus upward toward the liver will cause symptoms very much resembling infectious gall-bladder disease, which will be referred to under differential diagnosis. The latter direction has resulted, in neglected cases, in an abscess beneath the liver, rupture through or behind the diaphragm, and entrance of the pus into the lung and pleural cavity from which it has been actually evacuated by coughing and expectoration. If an appendiced abscess is small recovery might occur without operation, though such a happy result is doubtful. The disease is progressive, and the pus tends to increase, and if not evacuated will frequently rupture the walls of the containing cavity, into the cecum occasionally, but more often, unfortunately, into the peritoneal cavity, with a resulting general purulent peritonitis and a nearly inevitably fatal result. In such a case the pulse increases in frequency and becomes full and strong, the face becomes pinched and anxious, eyes brighten, the mind becomes active, though delirium appears later, the abdomen slowly dis-

tends, accompanied by marked pain and restlessness of the patient. These three pathognomonic conditions, a bright eye, an active mind, and a swollen belly, indicate approaching dissolution. The distension is due to a paralysis of the bowels, and gas and feces are retained in spite of all treatment. Nausea and vomiting soon begin, the latter at first green, but later black, from emptying of the contents of the intestines into the stomach. Death rapidly follows. The diagnosis of appendicitis from other lesions of the abdominal cavity, if seen early, is comparatively easy in the great majority of cases. Particular attention must be paid to the history of the patient, and especially to the character of the onset of the illness and the earlier symptoms. While inflammation of the stomach and intestines (gastro-enteritis) has caused some confusion at times, yet unfortunately the mistake is made more often in the wrong direction. That is, a true attack of appendicitis is thought to be gastro-enteritis and treated accordingly until the appearance of an abscess with its unmistakable symptoms warns the attending physician of the true nature of the malady with which he is dealing. While the pain in both diseases may begin over the stomach (in the epigastric region) and continue over the whole abdomen, in appendicitis the region of the appendix will be tender to palpation from the onset, and this tenderness will persist and even become more acute after the general abdominal pain has ceased. Unilateral rigidity is quite constant in the beginning of the appendiceal attack, while in the gastro-intestinal disease the entire abdomen may be rigid. In certain cases of gastric ulcer, with perforation and escape of stomach contents into the peritoneal cavity, the shock is more marked from the onset, while the beginning and the more severe symptoms will be found in the upper abdomen. Ulcer of the stomach is much more common in women than men, and often gives symptoms which can be recognized long before the ulcer has advanced to the stage of perforation. In enteritis, or inflammation of the bowels, and particularly when poisonous food products have been eaten, the symptoms produce early and often marked shock. In the summer months iced drinks are a frequent cause of this complaint. About 18 hours after the dietary indiscretion there will be marked general abdominal pain, diarrhœa, chilliness, perspiration, and a feeling of great weakness. In severe cases the depression may be so pronounced as to cause death (acute ptomaine poisoning). The greatest area of tenderness will be found about the centre of the abdomen, and careful palpation of the appendix region may find this organ not enlarged or tender.

Mention was made earlier in this article of the symptoms produced by inflammation of an appendix behind the cecum and pointing upward toward the gall-bladder. In such instances the symptoms produced resemble very closely those due to inflammation of the gall-bladder and sometimes the two diseases cannot be differentiated with certainty. But as both affections require surgical intervention to effect a permanent cure, and as the incision in both instances is made in nearly the same place, the failure to make a correct diagnosis is not detrimental to the patient. The pain in the gall-bladder affection, if referred, will cause a dull pain in the region of the liver and then upward to the right shoulder blade. Tenderness is limited to the gall-bladder region and is a very important symptom if the rigidity of the right rectus muscle does not prevent palpation. The appearance of jaundice, or the well-marked gallstone colics, would decide the diagnosis. Later in the progress of the disease, the infection of the gall-bladder may produce pus, or empyema, as it is called, and the gall-bladder can be palpated as a round, tender, and firm mass beneath the edge of the ribs and moving with respiration. An appendiceal abscess would rarely reach as high as the costal margin without implication of the right iliac fossa, and in a high position might be mistaken for a ruptured gall-bladder following empyema. In such a case the diagnosis would be nearly impossible and immaterial, as the treatment necessitates an operation. Neither an infected gall-bladder nor an appendix should ever be allowed to advance to the purulent stage without an operation being advised. Inflammation of the fallopian tubes has been mistaken for appendicitis and *vice versa,* particularly when the tube leaking into the pelvic peritoneum causes a localized inflammation of that membrane. With the knowledge that the appendix frequently occupies the pelvis and may lie adjacent to the tube, the exact diagnosis of acute appendicitis from acute salpingitis may be difficult, and in chronic cases even more so. From the close proximity to each other which the two organs may hold, the tube may be infected from the appendix or the latter may become involved secondarily from a pyosalpinx (pus in the tube). This complicates the differential diagnosis still further. If a history of specific infection can be obtained with symptoms indicating the commencement of the disease in the lower part of the abdomen, and a vaginal examination showing induration of the vault with tenderness to pressure on either side of the uterus, the diagnosis may reasonably be made of salpingitis. A number of other diseases may be suspected in deciding upon a diagnosis. Among these may be mentioned extra-uterine pregnancy, some kidney affections, ovarian cysts, intestinal obstruction, typhoid fever, pancreatitis, etc. The nature of this article does not warrant the full discussion of these affections. The treatment of appendicitis has been a mooted question for some time, and it has only been within the last few years that the medical profession has accepted the dictum of those whose experience with the disease has been the greatest, that appendicitis is a surgical disease. The soundness of this teaching rests upon the fact that it is impossible to foretell in any individual case what the outcome will be, and what case will terminate favorably, or which will progress to perforation or gangrene, and the attendant peritoneal and other complications and sequelæ. It is essential that physicians appreciate the importance of early operation, as although there may be a few patients who for various reasons will refuse operation, the majority will depend upon the attending physician for advice and accept the treatment which he advocates.

The mortality of the early operation, before the peri-appendicular structures have become involved, is *nil,* barring accidents, and the incision

in the rectus muscle can be so closely approximated that the abdominal wall is not weakened in the slightest by the operation. The peritoneum, sheath of the rectus muscle and skin, are usually sewed up in tier suture,— that is, in layers,— and the resulting scar about two inches long can barely be perceived after the lapse of several years. As the disease progresses the mortality increases in direct proportion to the extent to which the peri-appendicular structures have become involved. When an abscess develops, the search for the diseased appendix is difficult and often dangerous, and many surgeons simply evacuate the pus cavity and establish drainage. But the presence of a necrotic appendix is a constant menace, frequently causing secondary pus collections which may result fatally in the end. In all cases where pus is found the employment of drainage is necessitated. This means that sterile gauze must be so disposed that the purulent material is caught up and carried off by capillary drainage and the abscess cavity forced to heal from the bottom upward, avoiding «pocketing.» The course of these cases is tedious and the convalescence prolonged. The dangers incident to acute appendicitis with abscess are attendant with great risk to life. The most dreaded is peritonitis with invasion of the entire peritoneal cavity by the purulent and infectious products due to rupture inwardly of the abscess. Nearly every patient developing general peritonitis from an appendiceal abscess will die in spite of the most careful treatment and skilful operation. In advanced stages of the disease, when the appendix becomes necrotic and gangrenous, the cecum will frequently be implicated and be so diseased that the removal of the appendix cannot be followed by closure of the wound in the cecum. In cases of this character gauze must be so placed as to isolate the fistulous opening from the general peritoneal cavity, hoping that, by granulation, spontaneous healing of the bowel opening will take place; but this does not always follow, and in such instances the hole in the cecum becomes a fecal fistula, discharging the contents of the bowel through the wound in the side. Fistulæ require very frequent dressing, heal slowly, and are extremely annoying and disgusting to the patient. A third complication which may result in abscess cases is intestinal obstruction. Earlier in this article the way in which adhesions form was described. They are nature's barriers against infection, but sometimes prove a veritable boomerang. The author has more regard for the results of the aseptic scalpel of the surgeon administered at the opportune season than he has for nature's attempts to cure. It is well known that after burns of the hands the resulting scar tissue will cause contraction and deformity of the fingers. The adhesions uniting the coils of intestines together to prevent the spread of infection may encircle the bowel, and, contracting, occlude its lumen, obstructing the flow of bowel contents and necessitating a second operation the mortality of which is quite high. Finally, if convalescence is uninterrupted, the wound slowly healing by granulation, the resulting scar is quite weak and nearly always results in a hernia (rupture).

In consideration of the facts that the course of appendicitis can never accurately be foretold, and that the dangers resulting from delay in operation are many and severe, the following outline of treatment is justified from present knowledge of this disease: Upon the appearance of severe pain in the abdomen, with the maximum intensity over the region of the appendix, nausea, or vomiting, and a point of tenderness in the right iliac fossa, the patient should be placed at rest, all food withheld, and the family physician sent for. When the attending physician has made the diagnosis of appendicitis there is no treatment to be discussed save operative interference. Whether the operation should be performed immediately will depend upon the extent of peritoneal involvement, but this question should be decided by the surgeon called into consultation and in whose hands the management of the case belongs. In those fatal cases which have been followed by a reopening of the wound a study of the ascertained conditions is of great interest. When death has taken place from a rapid septic poisoning or toxemia the abdomen may show nothing except some thin cloudy fluid in the pelvis and congestion of the peritoneum covering the intestines, giving them a «scalded» appearance. In the abscess cases the right iliac fossa is found filled with a green purulent exudate adhering closely to the groin and intestines. There may be small quantities of pus which have formed since the operation. If death does not occur for several days after operation, and nature fails to check the spread of the disease, this purulent exudate may reach from the liver to the pelvis with infection of the portal vein, liver, and of the lymphatics behind the peritoneum. With extensive leakage the entire peritoneal cavity may be filled with a foul-smelling, greenish-colored pus, with gangrene of the cæcum.

John B. Deaver, M.D.,
Specialist, Philadelphia, Pa.

Appenzell, ä'pĕn-tsĕl, a canton of Switzerland, wholly enclosed within the territory of the canton of St. Gall, and, though covering an area of only 162 square miles, divided into two independent portions, Ausser-Rhoden, or Outer-Rhodes, which is Protestant, and Inner-Rhoden, or Inner-Rhodes, which is Catholic. It is an elevated district, traversed by branches of the Alps; has large tracts of rich pasture-land and extensive forests of pine, and is watered by the Sitter and by several smaller affluents of the Rhine. The climate is cold, but healthy. Glaciers occupy the higher valleys. Flax, hemp, grain, fruit, etc., are produced, but the wealth of Inner-Rhodes, the more elevated division of the canton, lies in its numerous herds and flocks: that of Outer-Rhodes in its manufatures of muslins, gauzes, cambrics, and other cotton stuffs. The construction of railways has now made the canton more accessible, and great numbers of strangers flock hither annually to take advantage of the whey-cure establishments of Gais, Weissbad, Gonten, Heiden, and Heinrichsbad. The inhabitants speak a peculiar dialect, which even those who are well acquainted with Swiss-German have great difficulty in understanding. The town of Appenzell (German, *Abtenzelle*, abbot's cell), is the capital of Inner-Rhodes, beautifully situated on the Sitter, with 4,369 inhabitants. Trogen, with 2,578 inhabitants, is the capital of Outer-Rhodes. Schools

are numerous, and education widely diffused. The division between the Protestant and Catholic portions of the canton has existed since 1597. They have only one vote between them, and send deputies to the federal assembly in turn. Pop. (1900), Outer-Rhodes, 55,281; Inner-Rhodes, 13,499. The former is one of the most densely-peopled parts of Europe, its population being equal to more than 500 per square mile. See Richman, 'Appenzell' (1895).

Ap'percep'tion, a psychological term referring to higher consciousness. Until recently there has been considerable confusion among English and American writers on psychology as to the meaning of the terms perception and apperception. To point out the source of this confusion requires a brief history of the term apperception. The word was first used by Leibnitz in connection with his philosophy of "windowless" monads. With him every human soul is a monad which develops by an inner unfolding. When this development reaches the point of clear self-conscious being it attains what he calls apperceptive consciousness. If, on the other hand, the development is only partial, if its states are vague and only partially self-conscious, the monad has attained the level of perceptive consciousness. Thus for Leibnitz the terms perception and apperception designated simply different degrees of clearness and distinctness of consciousness, with no reference whatever to the apprehension of external things. In fact the theory of Leibnitz rendered any such use of the terms impossible. In more recent German psychology the term perception has been dropped and that of apperception retained as an expression of all the higher forms of clear consciousness. There is, however, one important exception to this. Wundt has retained both terms and attempted to restore to them their Leibnitzian meaning without, of course, committing himself to Leibnitzian monadology. Mental processes which are clear and distinct and are also under the control of volition are called by Wundt processes of apperception. But when the mental act is merely association in character and not directly controlled by volition, or when it is obscure, Wundt calls it an act of perception.

The philosophy of Herbart doubtless, more than that of any other German writer, has brought the term apperception into prominence in American psychology. If we consider his system we shall find that here again the terms perception and apperception mark different degrees of clearness and completeness of the forms of mental activity. With Herbart all mental processes are but the interactions of ideas. When a new idea enters the mind it causes a connection among the ideas already present. It disturbs the equilibrium. It is welcomed by the ideas akin to it, and opposed by those which are not. When it finally becomes adjusted and settled into its proper position among pre-existing ideas the new relation thus brought about is the result of apperception. Coming over to English and American psychology we meet with that difficulty and confusion referred to above. This confusion had its origin in the fact that in translating the Leibnitzian terms perception and apperception into English these same identical terms were used, regardless of the fact that in our psychology we had already a term, perception, which had acquired a fixed and definite meaning. The English word already in use stood for the recognition of objects through the senses, and this is still its meaning. Hence it stands for the clear and self-conscious recognition of things as well as the vague and imperfect apprehension of them. The term perception brought over from German psychology, and the same word already in use, thus stood for widely different meanings, and hence the confusion. The Germans have a wholly different word (*wahrnehmung*) for what we mean by perception, and consequently they cannot understand our difficulty. The result is that we have all along used the terms perception and apperception as though they distinguished wholly different mental activities instead of marking only different degrees of the same processes, as they actually do. Apperception is only clear and self-conscious perception. It involves in a highly complex way the various mental processes of memory, imagination, judging, inferring, etc., when these processes are clear and self-conscious. A full treatment of apperception therefore requires that these processes be taken into account. It is only necessary here to indicate briefly something of the pedagogical bearing and value of the term. Mainly through the influence of the so-called Herbartian movement in America, this term apperception has centered attention upon, and emphasized the importance of, the processes involved and the conditions requisite for the successful acquisition and assimilation of new knowledge with that which has already been learned. As the bodily organism separates and assimilates only such elements of the food taken into it as are needed for its growth and repair, so in a somewhat similar manner does the mind select and appropriate only such of its presentations as manifest a certain kinship to what is already consciously and vitally present, and rejects the rest. Elements wholly foreign to the mind's present stock of ideas escape it altogether. We must therefore learn the new by means of the old. Hence before presenting the new it is necessary to call up and make alive, by arousing interest and curiosity, those ideas and materials of knowledge that by similarity or other bond of relation will best serve for the ready reception and complete assimilation of the truth or fact to be taught. The goal of intellectual development is mainly the acquisition of clear, distinct, and adequate general conceptions, and the ability to make correct application of these to new particulars as they arise, or to see in each new fact the old in disguise.

In the development of such general conceptions, two stages are recognized which may be appropriately designated by the terms perception and apperception of German psychology, if these terms be employed without reference to whether the mental facts considered are externally or internally derived. The process in the first stage is for the most part involuntarily and unconsciously directed, in the second it is voluntary and self-conscious. The process is not, however, first, sense impression, then percept, concept, judgment, and reasoning in turn, each leaving off where the next higher begins. It dates its origin far back in the mental history of each individual, and all along in actual experi-

ence, sensing, perceiving, conceiving, judging, etc., are inextricably joined in one indivisible movement of thought-development. To use James' expressive phrase, the infant's consciousness is a "big, blooming, buzzing confusion." This is the child's world. It is not, however, a world with which he can be satisfied. It must be broken in pieces and continually made over again. Chaos must be made cosmos, the irrational must become progressively rational. In fact, to rationalize the "big confusion" becomes the great and never-to-be-finished work of education and of life. Therefore the manner of this rationalization is of especial interest to the teacher. The "confusion" is not monotonous. It is not always the same. There is change. Certain elements come and go and some of them return again. By repeated recurrence these elements come to stand out in the foreground of the dark "confusion." Some of them are uniformly repeated together simultaneously or in close succession. These consequently become associated and form the basis of perception. Perception occurs when the presentation of one element immediately calls up the others belonging with it in the unity of consciousness which these elements represent. The presented element or sensation becomes the sign to which the mind at once adds the proper interpretation and accompaniment. The richness of the interpretation depends upon the mind's present attitude and condition, and its past experiences with the object presented. In other words, in all perception there is more or less of apperception.

CLOYD MACALLISTER,
Yale University.

Appert, a'pār, **Benjamin Nicolas Marie,** a French philanthropist prominent in educational matters: b. in Paris, 1797; d. 1847. He made a careful study of prison conditions, spending much time in this pursuit, his researches being published in his 'Journal des Prisons' (1825-30). He was much opposed to solitary confinement and is said to have taught 100,000 soldiers to read and write. Besides the 'Journal' he published 'Dix Ans à la Cour du Roi Louis Philippe' (1846), and 'Conférences contre le Système Cellulaire.'

Appert, a'pâr, **Nicholas.** a French scientist, brother of Benjamin Appert (q.v.): b. 1750; d. 1841. His method of preserving food without chemicals is given in his 'Art of Preserving Animal and Vegetable Substances' (1811). It is the familiar method of placing the article to be preserved in a can after heating, and then hermetically sealing it, and for his invention he was awarded a prize of 12,000 francs from the French government.

Ap'petite, a term in its widest sense denoting the natural desire for gratification, either of the body or the mind; but generally applied to the recurrent and intermittent desire for food. A healthy appetite is favored by work, exercise, plain living, and cheerfulness; absence of this feeling, or defective appetite (*anorexia*), indicates diseased action of the stomach, or of the nervous system or circulation, or it may result from vicious habits. Depraved appetite (*pica*), or a desire for unnatural food, as chalk, ashes, dirt, soap, etc., depends often in the case of children on vicious tastes or habits; in grown-up persons it may be symptomatic of dyspepsia, pregnancy, or chlorosis. Insatiable or canine appetite or voracity (*bulimia*), when it occurs in childhood, is generally symptomatic of worms; in adults common causes are pregnancy, vicious habits, and indigestion caused by stomach complaints or gluttony, when the gnawing pains of disease are mistaken for hunger. See DIETETICS; DYSPEPSIA.

Appiani, ä'pe-ä'ne, **Andrea,** an Italian painter: b. in Milan, 23 May 1754, of noble but poor family; d. in 1817. He visited Rome three times in order to penetrate the secret of Raphael's style of fresco-painting, and soon excelled in this art every living painter in Italy. He displayed his skill particularly in the cupola of Santa Maria di S. Celso at Milan, and in the paintings representing the legend of Cupid and Psyche, which he prepared for the walls and ceiling of the villa of the Archduke Ferdinand at Monza (1795). Napoleon appointed him royal court-painter, gave him the order of the Legion of Honor and that of the Iron Crown, and made him member of the Italian Institute of Sciences and Arts. Appiani painted afterward almost the whole of the imperial family. His best works are the fresco-paintings on the ceiling of the royal palace at Milan, allegories relating to Napoleon's life, and his 'Apollo with the Muses,' in the Villa Bonaparte. Almost all the palaces of Milan have fresco-paintings by him.

Ap'pian of Alexandria, the governor and manager of the imperial revenues under Hadrian, Trajan, and Antoninus Pius, in Rome. He wrote a Roman history, from the earliest times to those of Augustus, in 24 books, of which only 11 have come down to us. It is written in Greek, in clear and simple style; but it is little else than a compilation, characterized by many inaccuracies and absurd blunders. The best modern edition is that of Schweighäuser.

Ap'pian Way, a famous Roman highway leading from Rome to Capua by way of Bovillæ, Aricia, Terracina, Formiæ, Minturnæ, Sinuessa, etc.; called by Statius *Regina Viarum,* the Queen of Roads. It was made by Appius Claudius Crassus Cæcus when he was censor, 313 B.C., and afterward extended to Brundusium by way of Beneventum. It was paved with hexagonal blocks of lava, exactly fitted to one another, resting on an admirable substructure of considerable depth, and there may still be seen, particularly at Terracina, important remains which prove its excellent workmanship. See ROADS AND HIGHWAYS.

Ap'pius Clau'dius Cras'sus, a Roman patrician, of the family of the Claudii. In 451 B.C., when the decemvirs were appointed to compose a complete legal code for Rome (afterward known as the Laws of the Twelve Tables), and to wield the supreme power in the state for a

year, Appius Claudius was chosen one of the ten, and when the office was continued for another year he was re-elected. As he and some of his colleagues had ruled in a very tyrannical manner, the people had become incensed against them, and the following circumstances led to their overthrow. Appius Claudius had conceived an evil passion for a damsel named Virginia, the daughter of Lucius Virginius, a respected plebeian, and at his instigation Marcus Claudius, one of his clients, claimed Virginia as the daughter of one of his own female slaves and offered to prove this even to the satisfaction of her reputed father, while Appius Claudius decided that in the meantime she should remain in the custody of the claimant. This decision being directly contrary to law, and Icilius and her uncle Numitorius having exposed the decemvir's criminal designs, the aspect of the people became so threatening that he was forced to leave the maiden in the hands of her family, declaring, however, that he would finally settle the case next day. Virginius, hastily summoned from the army, appeared with his daughter next day in the forum in mourning robes and appealed to the people; but Appius Claudius, attended by a strong guard, again adjudged her to M. Claudius. Unable to rescue his daughter, the unhappy father snatched a knife from a butcher's stall and plunged it into her bosom, saying, "There is no way but this to keep thee free." Virginius escaped to the camp and with the army returned to Rome, demanding revenge. The decemvirs were deposed by the indignant people, and the government by tribunes and consuls restored 448 B.C. Appius Claudius died in prison or was strangled, while Marcus Claudius was banished.

Ap'ple, the name given to a low round-headed tree (*Pyrus malus*) of the natural order *Rosaceæ*, with compact clusters of flowers which appear with the thick woolly short-stemmed leaves and followed by fruits botanically known as pomes. It is a native of south-eastern Europe and contiguous Asia, whence it has been spread by man as a cultivated plant to all temperate climates of the globe. It has been more or less hybridized with its close relative, *P. baccata*, the well-known Siberian crab, a smoother, more wiry species coming from a somewhat more northeastern district. This latter species has thinner, smoother, longer-stemmed leaves and fruit-stems than the other; the deciduous calyx of its smaller, harder fruits is also a striking difference, the calyx of the other being permanent. Certain hybrids of these two species are known as *P. prunifolia*. Besides these Old-World species and their progeny there are two American species, *P. coronaria*, of no culinary value, but of use as an ornamental plant, and *P. ioensis*, a promising species which, by crossing with *P. malus*, has given rise to the hybrid race, *P. soulardi*, remarkable for its hardiness. The term crab is loosely applied to small, long-stemmed apples as well as to varieties of the two leading species mentioned.

Commercial Importance.— If not the leading fruit of the world, a status few will question, the apple is certainly the most important fruit of the temperate zones, a rank which it merits for the following reasons: When the market is glutted it can be disposed of in more ways than any other fruit (see BY-PRODUCTS, below); a large number of its varieties keep well, withstand shipment to and sell well in distant markets; the tree readily adapts itself to great extremes of climate, soil, and other conditions. It is, in fact, the only fruit that has passed the bounds of luxury and become a staple article of food except in the tropics. Its range extends in the northern hemisphere from Scandinavia to the mountainous parts of Spain, from New Brunswick to the high lands of Georgia, and from British Columbia to the mountains of Mexico. The great apple-producing countries of the world are the United States, Canada, Australia and adjacent islands, Russia, and Germany. In America the principal apple districts are Nova Scotia, New England, New York, Pennsylvania, Ontario, Ohio, Michigan, Kentucky, and the central western States. Other less extended or younger districts are the Piedmont sections of Virginia, West Virginia, North Carolina, Tennessee, etc., the Pacific Coast States, and British Columbia.

From the eastern regions a steady export trade has been growing, mainly with British ports, and when the eastern crop is short, Pacific coast apples are shipped across the continent in large quantities to eastern markets. According to Bailey a full crop of the United States and Canada "of all kinds and grades, is probably not less than 100,000,000 barrels." The Twelfth Census Report of the United States gives the number of trees standing in 1900 as follows: Missouri, 20,040,399; Illinois, 13,430,006; Ohio, 12,952,625; Kansas, 11,848,070; Pennsylvania, 11,774,211. The total number of apple trees in orchards at that date was 201,794,764 as compared with 120,152,795 in 1890. When compared with the figures of the previous census the extension of orchard-planting seems to be greatest in the central western States, especially in Missouri. The crop reported for some of the States in 1899 (see Census Report) are as follows: New York, 24,111,257; Pennsylvania, 24,060,651; Ohio, 20,617,480; Virginia, 9,835,982; Illinois, 9,178,150. The crop of New York and Pennsylvania was 34.1 per cent of the total crop of the United States — 175,367,626 bushels in that year. In 1889 the crop was 143,105,689 bushels. The report further states: "The apple has a decided primacy among American fruits. Of the orchard trees reported in 1900, 55 per cent were apples, and of the bushels of fruit reported, 82.8 per cent were of that variety. In 10 years the number of apple trees increased more than 80,000,000, yet the number of other fruit trees increased so much faster that the apple trees, which constituted 62.1 per cent of all in 1890, were only 55 per cent in 1900. . . . The apple crop of 1899, taking the country as a whole, was more nearly a normal one than was that of any other orchard fruit. Further, the average production of apple trees, being larger than that of other trees, affects the total in such a comparison . . . more than does the number of trees. The apple increased its proportion of the total production of orchard fruits from 76.3 per cent in 1889 to 82.8 per cent in 1899.

Varieties.— In addition to productiveness, an essential to the value of any food plant, the 12 points mentioned and explained below should be looked for in an apple variety. Of course all 12

1. An apple orchard in Delaware. 2. A Baldwin apple orchard in New York.

of these qualities cannot be found greatly developed in a single variety because some are in a measure antagonistic, but by keeping these points in mind the prospective orchardist may avoid planting a variety that would not meet his own expectations or the market demands. (1) Richness, dependent upon the relative proportion of sugar to malic acid. When these are deficient in amount the fruit is insipid, but each may be present in large amount without making the fruit pronouncedly sweet or tart to the taste. Many tart apples contain more sugar than some of the so-called sweet apples. In ripe specimens of improved varieties the range of acid is from 0.19 to 1.11 per cent, and of sugar from 10 per cent or even less in poor sorts to 14 per cent or somewhat more, the usual range being from 11 to 13 per cent. (2) Flavor, a quality distinct from the taste of acid and sugar, and, like perfume, dependent upon minute quantities (seldom more than 0.5 per cent) of a volatile oil. A highly perfumed apple is, however, not necessarily highly flavored. (3) Firmness not sponginess, crispness not hardness, tenderness not softness, meltingness not juiciness are dependent upon cell structure. (4) Color is often of more importance in the uneducated market than form, size, richness, and flavor combined. It is an unsafe index of the last two qualities, except that, as a rule, well-colored specimens are superior to poorly colored ones of the same variety. Color varies in all varieties with season, soil, management, etc. The favorite color in the general market is red. (5) Form: a nearly globular shape is most desirable because fruits of that form pack better without bruising than other forms. (6) Size and uniformity. In general, a diameter of about three inches and a weight of six or eight ounces is preferred, and a variety producing such as the bulk of its crop will usually, on account of the lessened necessity for grading, be more valuable than another variety of equal productiveness but with widely varying size of fruit. (7) Smooth, tough, but thin skin resists insect and fungous attacks, injuries in handling and shipping, and are more economical with respect to waste. (8) Small core and few seeds, save waste. (9) Maturity: The commercial variety should be ready to harvest all at once. (10) Firm adherence to the tree; self-evident. Defectiveness in this respect may be due to attacks of enemies. (11) Culinary qualities: of prime importance in commercial varieties because such are used mainly for cooking. Sweet varieties usually make insipid pies but good baked apples; tart varieties make best pies and sauce. (12) Good-keeping is not dependent solely upon firmness but is usually associated with locality, climate, soil, etc., as well as with the variety and the stock upon which it is grown.

Another matter of importance in the selection of varieties of apples, and even more markedly of pears, is the determination of the fertility of the blossoms. Sterility, indicated by annual dropping of the fruit, may result from one or a combination of the following causes. Impotence of the pollen or the pistils, or the premature ripening of one or the other; injuries to the blossoms by fungous attacks, rain, frost, or continued cool weather or other cause more or less beyond the grower's control. On the other hand, it often results from impotence of the pollen to fertilize the pistil of the same variety and is noticed when trees stand singly or in blocks of one variety remote from other varieties. This may be obviated by the grower, who should plant varieties that blossom at the same time in proximity, usually in alternate rows through the orchard, or by grafting such in orchards already set. A practice resulting from this and the varying maturity of varieties with respect to fruit-bearing is the planting of «filler» trees in permanent orchards. The fillers are quick-maturing varieties of usually upright growth and small size, which are set alternately with the slower-growing more-spreading permanent trees, and cut out when crowding seems to threaten. For such practice four varieties are usually selected, two fillers and two permanents, each pair blossoming at the same time. Each pair is placed alternately with the other and each member of the pair alternately with its partner. Trees in such orchards are often planted 28 feet apart on the diagonal, so that when the fillers are removed the permanents will be left in rectangles of about 40 feet, the usual distance recommended for large-growing varieties. Some growers plant as close as 30 feet, but this is too close except for trees of small growth. No other tree fruit than the apple should be planted in an apple orchard, because no two fruits demand the same treatment, and where two are planted, one or the other, perhaps both, must suffer more or less. See ORCHARD.

Propagation.— New varieties of apples are propagated from seeds, but since seeds rarely improve upon the parent, seedlings are chiefly used to produce stocks for grafting or budding. Standard (that is, natural-sized) trees are so propagated. Dwarf trees result from grafting or budding the same varieties upon the small-growing, almost bush-like varieties, paradise and doucin, the stocks of which are produced by mound layering. Voluminous discussion has arisen concerning the relative advantages of grafting over budding, and also concerning certain methods of grafting. Opinions in the first case are very conflicting; in the latter they seem to favor the use of a small piece of apple-root as stock and a rather long scion to be set deeply in nursery and orchard in order to ensure the rooting of the scion and thus obtain a tree drawing its nourishment from its own roots instead of from the nondescript roots of the seedling stock. In northern rigorous climates very hardy varieties are selected upon which to top-work less robust sorts, thus to increase their hardiness. When the trees are set the tops must be cut back severely to balance the loss of root due to digging from the nursery and to start the head at the proper height from the ground. Formerly six feet was the usual length of trunk desired, but half that length is now preferred and in the central Western States even less. Trees with short bodies and low heads are less likely to be injured by wind and sun-scald than those with high heads and long bodies. Established unprofitable trees and undesirable varieties are often top-worked to valuable ones; not more than a third of such trees being grafted each year because of the danger of producing water-sprouts. See GRAFTAGE; PRUNING; TRANSPLANTING.

Soils, Fertilizers, etc.— Apples thrive upon nearly all kinds of soils, certain varieties being better adapted to light soils and others to heavy rather than the reverse in each case; but the great majority of the almost innumerable varieties succeed best upon medium to clayey loams, especially if they are somewhat elevated, inclined, or rolling, and in a clear, dry climate. Since air and water drainage are usually good in such places the fruit produced is generally of fine color, flavor, and size. Upon low lands and in damp climates the fruits are usually of inferior quality and the trees more susceptible to fungous attacks. (See ORCHARD.) The fertilizers demanded by apples are mainly potash and phosphoric acid. (See MANURES.) Some growers use a mixture of 100 pounds of muriate of potash to 200 pounds of 16 per cent superphosphate at the rate of 100 pounds an acre while the trees are small, increasing to 500 pounds and even as much as 1,500 pounds an acre for trees in full bearing, the amount depending upon the character and condition of the soil, and the grower's management. If cover crops (see GREEN MANURING) such as clover, vetches, or cow-peas are grown, they will supply all the nitrogen needed; indeed, if long continued or if several very heavy crops be turned under, too much nitrogen may accumulate, and recourse to a cereal crop be necessary to remove the excess. Too much nitrogen induces a sappy, easily winter-killed growth, generally at the expense of fruit-production. Lack of nitrogen is indicated by pale green or yellowish foliage. The preparation of the land does not differ materially from that for other crops such as corn or potatoes, each of which is often grown the season previous to planting in order to fit the land for the orchard. The trees may be set in spring or autumn and the cost of cultivation may be met by cropping the land for the first few years with potatoes, melons, or some other low-growing, inter-tilled crop. Annual cultivation consists in an early spring plowing followed by narrowings at intervals of two weeks and after rains that form a crust until mid-summer, when a cover crop is sown to be turned under in the following spring. Deep plowing during the first five years or so will induce deep rooting which in after years will assist in withstanding drouth and obviate the necessity of annual deep plowing. See TILLAGE.

Growers opinions differ as to the length of trunk an apple tree should have, and also as to whether there should be a main trunk above the principal lower limbs, but all agree that a few (some growers say five, four, or even three) well-placed main limbs are better than a larger number. These mains should start far enough from one another to avoid the danger of splitting when under load of fruit, and should be made to re-branch near the main trunk. Some of these latter branches should be trained upward, the others more horizontally, so as to develop a well-rounded, symmetrical top. Four or five years' careful training should so fix the character of the tree as to obviate in great measure the necessity of subsequent pruning. See PRUNING.

Insects.— Several hundred insects feed upon the apple, but the most of them are so well controlled by their enemies or by natural checks that their injuries are seldom noticed. There are, however, many that are frequently troublesome, among which the following are perhaps the most commonly destructive. In connection with the specific means of control here mentioned, the reader should refer to the general article FUNGICIDE. (1) Codlin moth (*Carpocapsa pomonella*) is perhaps the best-known and most widely distributed apple pest. The eggs are laid upon the fruit, the larvæ almost invariably entering the calyx, burrowing through the flesh and causing premature ripening. Since two or even three broods are produced in a season, the destruction of the first by spraying is of prime importance. This spraying must be done before the calyx closes, because the caterpillar's first meal must be poisoned, to accomplish which the sepals must not have closed. The destruction of culls, cores, and parings and the use of moth-traps in the windows of storage-rooms also assist in controlling the pest. (2) Apple maggot (*Tripeta pomonella*), the footless grub (one fifth inch long) of a two-winged fly, tunnels in the fruit and is especially troublesome in New York and New England, attacking thin-skinned summer and autumn varieties. Windfalls may be eaten by stock running in the orchard, and stored apples may be fumigated with carbon disulphid. (3) San José scale (*Aspidiotus perniciosus*), a minute scale insect of enormous prolificacy found upon many species of woody plants which in a few years die. When full grown it so closely resembles some of its relatives that a microscopic examination is necessary to determine its identity. When abundant, infested twigs have a somewhat scurvy appearance resembling a coating of ashes. From beneath the female scale the young appear, crawl to new feeding ground, fix themselves, and reproduce with great rapidity. It has been estimated from careful records of close observations that more than three billion scales may be produced in a single season from one female. Spraying with kerosene emulsion, lime, sulphur, and salt solution, or fumigating with hydrocyanic acid gas, are the three popular ways of combatting this pest. (4) Canker-worm, the larvæ of certain moths (species of *Anisopteryx* and *Paleacrita*), most common in the northeastern United States and adjoining Canada. They attack the leaves of apple, pear, and some other trees, entirely defoliating them when especially abundant. The wingless females crawl up the trunks and lay their eggs upon twigs or bark. The larvæ, measuring-worms, appear shortly after the foliage from which, when disturbed, they drop at the ends of silk threads. If they reach the ground they climb the trunk to resume feeding. Pupation occurs in the ground. This climbing habit of both females and larvæ, especially of the former, suggested impassable bands upon the trunk as a means of control. To be most effective these must be applied just before the females begin to climb, and since those of one species are active in the late fall and upon warm days during the winter, and those of the other in the spring, the bands must be kept in good condition during most of the year. (Consult: New Hampshire Experiment Station Bulletin, No. 85, 1901.) (5) Tent caterpillar, the larvæ of a moth (*Clisiocampa americana*), attack various trees in a large part of the United States and Canada. The eggs

are deposited in gluey-looking masses upon the twigs in summer and hatch in very early spring. The larvæ are gregarious, and spin a protective web from which they emerge to feed. When numerous they frequently strip large limbs or even trees of foliage. Gathering the eggs during the winter and cutting off the nests as soon as seen are the two most effective methods of control. Since several parasites attack the eggs of this moth, the egg masses should be kept out of doors in a place from which the parasites, but not the newly hatched worms, can escape. (6) Web worm (*Hyphantria cunea*) is a caterpillar similar in habits to the preceding, but enclosing the foliage upon which it feeds inside a web until nearly full grown, when like the former species the larvæ disperse. The eggs are laid by a moth in late spring upon the undersides of leaves near the tips of branches of many trees, bushes, and even clover. Cutting and burning is the most effective remedy. (7) The round-headed and the flat-headed borers are serious pests. They bore in the young wood, the latter mainly near the ground in the trunk, the former more frequently in the larger limbs. They are the larvæ of two beetles (respectively, *Saperda candida* and *Chrysobothris femorata*). Their presence is indicated by the presence of chip-like castings at the mouths of their burrows. The only effective means of control are cutting out the larvæ or prodding them to death in their burrows with a flexible wire. The application of repellants to prevent the laying of eggs upon the trunks is sometimes recommended. (8) Woolly aphis (*Schizoneura lanigera*) often called American blight in England and Australia, is a serious pest, especially upon young trees. Two forms of this insect appear; one above ground, the other upon the roots. The former, readily recognized by its woolly appearance, is easily controlled by kerosene emulsion; the latter is hard to fight without injuring the trees. Tobacco dust worked into the ground seems to be the most effective and least harmful remedy. Nursery stock should always be carefully examined for this pest and treated, if necessary, before being planted. (9) Bud moth (*Tmetocera ocellana*), a tiny insect, the larvæ of which appear in midsummer, pass the winter in the larval state and attack the opening buds and young leaves, over which they weave a little web in early spring, when they are most destructive. Paris green is effective.

Diseases.— Apple scab (*Fusicladium dendriticum*) is probably the most serious apple disease, since it causes the loss of much fruit and injures the appearance of much more. It appears as black spots with grayish borders on apples and pears, commonly seen on greening, snow, and yellow harvest varieties that have not been sprayed. Often the abundance of the confluent spots prevents the normal development of the fruit, which becomes lop-sided. The leaves are also attacked, but the markings are not so pronounced. Spraying with Bordeaux mixture is very effective. Rust (*Rœstelia pirata*) appears upon the foliage in early summer as orange spots more or less confluent. The fruit is also destroyed. The spores of this fungus will not germinate upon the apple but find a congenial host in the juniper or cedar, upon which they are called cedar apples (botanically, *Gymnosporangium macropus*). These, when matured in the following spring, look something like orange yellow sponge. Their spores will not germinate upon the cedar, but will upon the apple. Sometimes the fungus perpetuates itself by its mycelium, which may live from year to year upon the young twigs and buds of the apple. Destruction of the cedars and spraying are effective. Apple canker (*Nectria ditissima*) destroys the bark and younger wood, and eventually the tree, but small areas may be cut out and the wounds painted with Bordeaux mixture. In fact, since this disease gains entrance through wounds, all such should be similarly treated. Burning badly infested trees is the only means of checking the spread of this disease. Powdery mildew (*Podosphæra oxycanthæ*), a grayish growth upon the foliage, is often troublesome in the South upon young trees and seedlings in the nursery. It may readily be controlled by a standard fungicide. Bitter rot (*Glœosporium fructigenum*) appears upon the fruit as brown spots, extending until they often involve the whole apple. It may attack at any time and is especially destructive to the early varieties, more in the South than in the North. Black rot (*Sphæropsis malorum*) resembles bitter rot and is similarly controlled. See FUNGICIDE.

Harvesting, etc.— As the fruit ripens, the starch which it contains becomes changed into sugar, the leaf green is replaced by tints characteristic of the variety, the flow of sap into the fruit diminishes until the apple has attained full size and weight, when the flow practically ceases. Since the changes that now take place are mainly chemical and continue independent of the tree, the fruit may be picked. Fruit-growers agree upon this time, which they determine with each variety from experience. The fruits are still hard, but have brown seeds, and, having reached the development mentioned, may be picked by slightly twisting the stem without danger of breaking the twig upon which it is borne, thus preventing a loss of bearing-wood. Fruits gathered at this time and ripened properly are superior to those allowed to hang longer upon the tree. For best results in keeping, apples should be stored as soon as possible after picking; the temperature kept uniform and near 33° F., so as to check the ripening process; draughts avoided, since they hasten decay and increase shrivelling, hence closed packages are better than shelves; odors should be excluded.

Cost of Production, Yield, etc.— From various sources the following annual averages of cost of growing an acre of apple trees to fifteen years of age have been compiled, the orchards in each case being managed according to approved modern methods. Plowing (once). $3.50; harrowing (seven times), $3.25; spraying (Bordeaux mixture and Paris green, four times) $5.00; fertilizers, $11.50; interest (at six per cent on land worth $100 an acre), $6.00; total, $34.55. Commencing at the age of from 6 to 10 years, according to variety, there should be a gradually increasing crop. At fifteen the orchard should be in nearly full-bearing. The cost of maintaining a New England orchard in full bearing was, per acre, as follows: Pruning, $2.50; plowing, $0.90; harrowing, $1.80; picking and packing, $12.50; barrels at 30 cents, $15.00; fertilizers, $2.50; spraying, $2.00; inter-

est (six per cent on land valued at $50 an acre), $3.00; total, $40.20. This orchard produced 50 barrels of No. 1 apples, which sold for $75.00. The plowing was probably done with a gang-plow, hence its low cost. Individual trees properly cared for often produce more than 10 barrels of fruit, and one New England orchard of young Fameuse apple trees produced in 1895 700 barrels and in 1896 1,000 barrels, which netted $1.90 and $1.00 a barrel, respectively. Waugh, who quotes these New England figures, remarks: «These results are not extremes; but they were secured by men who take care of their orchards.»

By-Products.— Apple culls may be used in more ways than the culls of any other fruit crop, and each product finds a ready market, mainly at home. The better specimens are usually evaporated, the cores and peelings of such being also utilized either for cider-making or more frequently they are dried and shipped to Europe for the manufacture of certain kinds of champagne and other wines. The others are usually made into cider, which in turn may be remanufactured into jelly, apple-jack, (apple brandy, a distilled liquor) or vinegar. When cider and apples are mixed and boiled with or without sugar the product is called marmalade, and, if spices be added, apple butter. The pomace (as crushed fruit is called, especially after the expression of the juice) is washed to obtain the seeds, which are dried and used for planting.

Bibliography.— Warder, 'American Pomology,' Part I., *Apples* (1867); Todd, 'Apple Culturist' (1871); Bailey, 'Field Notes on Apple Culture' (1886); Nebraska State Horticultural Society, Vol. XXV. 'The Apple,' (Lincoln, Neb. 1894); and various reports of horticultural societies, especially of the American Pomological, Michigan Pomological, and Western New York Horticultural societies; also various works on fruit culture. M. G. Kains.

Ap'ple Bran'dy, or Apple Jack, a liquor made from the fermented juice of apples by the ordinary processes of distillation.

Ap'ple of Discord, according to Greek mythology, the golden fruit thrown among the Olympian divinities by the goddess of discord (Eris), bearing the inscription «for the fairest.» Aphroditē (Venus), Hera (Juno), and Pallas (Minerva) became competitors for it, and its award to the first by Paris so inflamed the jealousy and hatred of Hera to all of the Trojan race (to which Paris belonged) that she did not cease her machinations till Troy was destroyed. This story is introduced in Tennyson's 'Œnone.'

Ap'ple of Sodom, the title of a fruit described by old writers as externally of fair appearance, but turning to ashes when plucked. It is probably the fruit of *Solanum sodomeum,* a nightshade (q.v.) of northern Africa, which when eaten may produce delirium and even death. An American nightshade is also so called.

Ap'ple-shell, the designation of one of the large, handsomely ornamented, globose, bush-climbing pond-snails of tropical Africa and America, belonging to the genus *Ampullaria.* Some species are to be found along the southern border of the United States. These mollusks are truly amphibious, having both lungs and gills, and are thus able to breathe in water or in air, whenever disposed to exchange an aquatic for a terrestrial existence. Consult Semper, 'Animal Life' (1881).

Ap'pleton, Charles Edward Cutts Birch, an Englishman of letters: b. in Reading, England, 16 March 1841; d. in Luxor, Egypt, 1 Feb. 1879. He was graduated from St. John's College, Oxford, in 1863, studied for two years in German universities, and was appointed lecturer in philosophy at St. John's College. His best service to literature and his time was his founding the 'Academy, a Monthly Record of Literature, Learning, Science, and Art,' whose first number appeared 9 Oct. 1869. Its characteristic feature was the signing of all the critiques and leading articles with the writers' names in full, and these included men of the highest eminence in literature and science. Appleton remained editor until his death. To a volume of essays on the 'Endowment of Research' he contributed two articles: 'Economic Character of Subsidies to Education,' and 'Endowment of Research as a Form of Productive Expenditure' (1876). See J. H. Appleton and A. H. Sayce, 'Life and Literary Relics' (1881).

Ap'pleton, Daniel, an American publisher: b. in Haverhill, Mass., 10 Dec. 1785; d. in New York city, 27 March 1849. After engaging in the dry-goods business in Haverhill, Boston, and New York, he began importing English books with his merchandise. He presently devoted himself exclusively to the business of printing and publishing, and between 1830 and 1849, in conjunction with his sons, laid the foundation for the successful career of the firm still known as D. Appleton & Co. Its publications extend over the entire field of literature, and it has rendered great service in issuing the works of modern scientists at moderate prices; for example, Herbert Spencer, Tyndall, Huxley, Darwin, etc. Medical books form a special department, and Spanish books for the South American market a specialty which the firm has made its own. In *belle-lettres* and American history it has a strong list of names among its authors.

Ap'pleton, George Swett, an American publisher, son of Daniel Appleton (q.v.): b. in Andover, Mass. 1821; d. in 1878. After following the publishing business for some years in Philadelphia he succeeded, in 1849, to his father's business in New York, with his three brothers.

Appleton, George Webb, an American novelist and dramatist, now resident in London: b. in New Jersey in 1845. He is author of the novels 'Frozen Hearts'; 'Catching a Tartar'; 'Jack Allyn's Friends'; 'A Terrible Legacy'; 'The Co-Respondent'; 'A Philanthropist at Large'; 'The Blue Diamond Mystery'; 'François the Valet'; 'Rash Conclusions'; 'The Romance of a Poor Girl'; 'A Forgotten Past'; of several plays, and of 'A Hundred Years of French History, 1789–1889.'

Ap'pleton, James, an American temperance reformer: b. in Ipswich, Mass., 1786; d. 1862. He served in the American army during the second war with England, and, removing to Maine, in later years entered the Maine legislature, where in 1837 he introduced a report

which became the basis of the famous Maine Liquor Law.

Ap'pleton, Jesse, an American theologian: b. in New Ipswich, N. H., 17 Nov. 1772; d. in Brunswick, Me., 12 Nov. 1819. After his graduation from Dartmouth College in 1792 he was ordained pastor of the Congregational Church at Hampton, N. H., in 1797. He was president of Bowdoin College, 1807–19. A man of fine culture and attractive personality, he was constantly in demand as a preacher on important occasions. His daughter married President Franklin Pierce. His lectures, sermons, and other writings, with a memoir, were published by Prof. A. S. Packard, 'The Works of Jesse Appleton, D.D.' (1837).

Ap'pleton, John, an American diplomatist: b. in Beverly, Mass., 1815; d. in 1864. He was secretary of the American legation at London, 1855–6, assistant secretary of state in 1857, and minister to Russia, 1860–1.

Ap'pleton, John Howard, an American scientist: b. in Portland, Me., 3 Feb. 1844. He was graduated from Brown University in 1863 and was instructor in chemistry there 1863–89, and professor since 1868. He has been professor of chemistry at Brown. He was a member of the United States Mint Commission in 1891. His chemical text-books have been widely used, and include 'Qualitative Chemical Analysis' (1878); Quantitative Chemical Analysis' (1881); 'Chemistry of the Non-Metals' (1884); 'Metals of the Chemist' (1891); 'The Carbon Compounds' (1892).

Ap'pleton, Nathan, an American merchant: b. in New Ipswich, N. H., in 1779; d. in 1861. He started the first cotton power-loom in the United States and was one of the founders of the city of Lowell. He sat several times in the Massachusetts legislature, and in 1830 and again in 1842 was a member of Congress.

Ap'pleton, Samuel, an American merchant, well-known as a philanthropist, brother of Nathan Appleton (q.v.): b. in New Ipswich, N. H., in 1766; d. in 1853. He retired from business in 1823 and at his death bequeathed $200,000 for benevolent and scientific purposes.

Ap'pleton, Thomas Gold, an American author and artist: b. in Boston, Mass., 31 March 1812; d. in New York city, 17 April 1884. He was graduated from Harvard University in 1831 and spent much of his life abroad. A generous patron of the fine arts, he was himself an amateur painter of considerable ability. In society he was a well-known figure, being a brilliant talker with a gift of epigram. His witticism, 'Good Americans, When They Die, Go to Paris,' has been erroneously ascribed to O. W. Holmes and others. His books are: 'A Sheaf of Papers' (1874); 'Nile Journal' (1876); 'Chequer Work: Tales and Essays' (1879); 'Syrian Sunshine' (1877); 'Windfalls' (1878). His poem "Faded Leaves," was once popular. See Susan Hale, 'Life and Letters' (1885).

Ap'pleton, William Henry, an American publisher, the eldest son of Daniel Appleton (q.v.): b. in Haverhill, Mass., 27 Jan. 1814; d. in 1884. In 1835 he was sent to represent his father's firm in London, and in 1836 a permanent agency was established there. In 1838 he was taken into partnership, and upon the retirement of his father in 1848 he formed a copartnership with his brothers to continue the house of Daniel Appleton & Co.

Ap'pleton, Wis., a city and county-seat of Outagamie County, on the Fox River and the Chicago & N. W. and the Chicago, M. & St. P. R.R.'s, 25 miles southwest of Green Bay. It is at the head of navigation on Lake Winnebago and on the Green Bay waterway, on a plateau 70 feet above the river, and near the Grand Chute rapids whence it derives excellent power for manufacturing. The principal industry is the manufacture of farm implements, furniture, paper, flour, pulp, machinery, and woolen and knit goods. It is the seat of Appleton Collegiate Institute and Lawrence University (Methodist Episcopal), and has university and public school libraries, three national banks, daily and weekly newspapers, and a property valuation of over $3,500,000. Pop. (1900) 15,085.

Appoggiatura, a-pŏd'ja-too'ra, a musical term applied to a small additional note of embellishment preceding the note to which it is attached, and taking away from the principal note a portion of its time. It is expressed thus:

 and performed  Long appoggiatura invariably occurs on the beat, and short appoggiatura, now commonly styled a grace-note, is written as an eighth note with a stroke through the stem.

Appoint'ment, the designation of an individual, by the person or persons having authority so to do, to perform the duties of some office or trust. The making out of a commission is conclusive evidence of an appointment to an office for holding which a commission is required. 1 Cranch, U. S. 137; 10 Pet. U. S. 343. An appointment is usually made by one person or a limited number acting with special authority, while an election is made by all of a class. In chancery practice an appointment is the exercise of a right to designate the person or persons who are to take the use of real estate. 2 Washb. R. P. 302.

Appold, ăp'ōld, **John George,** an English mechanician and inventor of automatic machinery: b. in 1800; d. 5 Aug. 1865. He invented a centrifugal pump, a brake which was used in laying the Atlantic cable, and a process for dressing furs.

Ap'pomat'tox Court House, a village in Virginia, 20 miles east of Lynchburg. It was the scene, 9 April 1865, of Gen. Lee's surrender to Gen. Grant, an event which virtually concluded the American Civil War.

Apponyi, ŏp'pō-nyĭ, **György (George), Count,** a Hungarian statesman: b. 1808; d. 1899. He was Hungarian court chancellor in 1847 and after some years of retirement entered the Reichsrath of Vienna in 1859 and was active in furthering schemes for the welfare of Hungary, materially assisting in bringing about the union of Austria-Hungary on the present basis. His son ALBERT APPONYI, a leading member of the Hungarian diet, is one of the most eloquent orators in Hungary.

Appor'tionment, a term signifying the division or distribution of a subject-matter in proportionate parts. In relation to contracts an apportionment is the allowance, in case of the partial performance of a contract, of a proportionate part of what the party would have received as a recompense for the entire performance of the contract. But where the contract is to complete a thing for a certain sum of money or other consideration, there can be no apportionment.

Apportionment - incumbrances.— The determining of the amounts which each of several persons interested in an estate shall pay toward the removal or in support of the burden of an incumbrance.

Apportionment-rent.— A term denoting the allotment of shares in a rent to each of several persons owning it. It is also applied to the determination of the amount of rent to be paid when the tenancy is terminated at some period other than one of the regular intervals for the payment of rent.

Appor'tionment Bill, the designation of a bill adopted by the United States Congress every 10 years, and directly after the completion of the Federal census, determining the number of members that each State is entitled to send to the National House of Representatives, and providing for the necessary reorganization of the Congressional electoral districts. The number of representatives has risen from 65 in 1789 to 386 in 1900, and the number of population to each member has advanced from 30,000 to 193,175, in the same period.

Ap'posi'tion, a grammatical term implying the relation in which one or more nouns or substantive phrases or clauses stand to a noun or pronoun, which they explain without being predicated of it, and with which they agree in case: as Cicero, *the orator*, lived in the first century before Christ; the opinion *that a severe winter is generally followed by a good summer* is a vulgar error.

Ap'prehen'sion (Latin *apprehensio*, from *ad* + *prehendere*, to seize), a term employed to denote the subjective character of perception. In the philosophy of Aristotle the act of attaining direct acquaintance with any truth or object of knowledge was called θιγεῖν, which figuratively means a touching or immediate contact with truth. The scholastics translated this term by the word apprehension, which has descended with modified and extended meaning to modern philosophy. This word has accordingly been employed to designate the act or faculty (1) of perceiving anything through the senses, (2) of forming an image in imagination, (3) of conceiving without judging, the so-called simple apprehension of nominalistic logic; or (4) a relatively simple and immediate act of intellection with or without reference to an external object. In this use of the word it distinguishes this form of intellection from the more complex and elaborated forms of knowledge denoted by the words comprehension, judgment, etc. Thus, for example, when an object or event is viewed apart from other things or events, it is said to be apprehended. When brought into systematic relations with kindred objects of knowledge we say it is comprehended. Stone makes a rather important distinction between implicit and explicit apprehension. Through frequent recognition of an object of knowledge the mind acquires the ability to distinguish and identify it as a whole without apprehending any of its constituent elements. The act which thus grasps its object without conscious combination or synthesis of parts is an implicit apprehension. If attention lingers upon the object, a tendency toward multiplicity arises, the component parts become discernible, and implicit apprehension becomes explicit. In the one there is a distinctionless unity; in the other a conscious synthesis. Implicit apprehension is a form of what Prof. Ladd calls the condensation of a series and is an important aim and result of correct mental training.

Wundt distinguishes apprehension from apperception, or what we should call clear and self-conscious perception, in a very suggestive though highly figurative way. He, of course, recognizes that in a series of temporally successive ideas or mental states the one immediately present in perception has the most favorable position as regards clearness and distinctness. Likewise, in a spatial series, or in a complex of simultaneously interconnected factors present in consciousness, some factors are more favorably located than others. There is, accordingly, a state of clearest grasp in consciousness, which, when accompanied by a special feeling, is called attention. This state of clearest grasp is figuratively styled the fixation point of consciousness, or, more briefly, the inner fixation point. In contrast the whole complex psychical content is called the field of consciousness. A conscious process which passes into an unconscious state is said to pass below the threshold of consciousness. A psychical compound which enters the field of consciousness passes on to the inner fixation point, then out again into the field, and finally descends below the threshold, is an apperceived compound. But just as such compounds may enter the field of consciousness before reaching the point of fixation, so may other compounds enter the field and pass out again without entering the fixation point at all. Such compounds are only apprehended. Thus it appears that Wundt's distinction between apprehension and apperception is simply one of relative clearness and distinctness of perception. Perceptions that are vague and unclear are called apprehensions, while those which are clear, self-conscious, and voluntary are apperceptions. Consult Wundt, 'Outlines of Psychology' (1897); Stout, 'Analytical Psychology' (1896).

In law, refers to the capture or arrest of a person on a charge of having violated the criminal law. Apprehension is the term usually applied to criminal cases, as one having the power, by virtue of his office, may arrest on civil process and apprehend on a civil warrant. See Arrest.

Appren'ticeship, in law, a contract by which a person called a master, who understands some art, trade, or business, undertakes to teach the same to another person, commonly a minor, and called the apprentice, who, on his part, is bound to serve the master, during a definite period of time, in such art, trade, or business. At common law an infant may bind himself apprentice by indenture, because it is for his benefit. But this contract, on account of its

liability to abuse, has been regulated by statute in the United States, and is not binding upon the infant unless entered into by him with the consent of the parent or guardian, or by the parent or guardian for him, with his consent. The contract need not specify the particular trade to be taught, but is sufficient if it be a contract to teach such manual occupation or branch of business as shall be found best suited to the genius or capacity of the apprentice. This contract must generally be entered into by indenture or deed. The contract is to continue, if the apprentice be a male, only during minority, and if a female only until she arrives at the age of eighteen. The duties of the master are to instruct the apprentice by teaching him the knowledge of the art which he had undertaken to teach him, though he will be excused for not making a good workman if the apprentice is incapable of learning the trade, the burden of proving which is on the master. Ordinarily the indenture should contain, among other things, a stipulation that the apprentice shall be taught the general rules of arithmetic. The master must not abuse his authority, either by bad treatment or by subjecting his apprentice to menial employments unconnected with the business he has to learn; but he may correct him with moderation for negligence and misbehavior. He cannot dismiss his apprentice except by consent of all the parties to the indenture. He cannot remove the apprentice out of the State under the laws of which he was apprenticed unless such removal is provided for in the contract or may be implied in its nature; and if he do so remove him the contract ceases to be obligatory. An infant apprentice is not capable in law of consenting to his own discharge. After the apprenticeship is at an end the master cannot retain the apprentice on the ground that he has not fulfilled his contract, unless specially authorized by statute. An apprentice is bound to obey his master in all his lawful commands, take care of his property, promote his interests, endeavor to learn his trade or business, and perform all the covenants in his indenture not contrary to law. He must not leave his master's service during the term of the apprenticeship. If, without the knowledge or consent of the master, an apprentice is employed by a third person, the master is entitled to all his earnings, whether the person who employed him did or did not know that he was an apprentice. In an action for harboring or enticing away an apprentice it must be shown that the defendant had a knowledge of the apprenticeship. The enlistment of an apprentice in the military service dissolves the relation of master and servant, and the master has no claim to the bounty money or pay of the apprentice so enlisted. A master cannot delegate to another the power to chastise his apprentice, as his authority is a personal one. At common law an apprenticeship is a relation which cannot be assigned, but if under such an assignment the apprentice continue with his new master with the consent of all the parties and his own, it will be construed as a continuation of the old apprenticeship.

Appro'pria'tion, a term denoting a specific sum set apart for the legislative power for a designated purpose. In the United States no money can be drawn from the Treasury excepting by appropriations made by law (Constitution, art. 1). Under this clause it is necessary for Congress to appropriate money for the support of the Federal government and in payment of claims against it. All bills for appropriating money originate in the House of Representatives, but may be amended in the Senate. The same procedure is observed in the several States.

Appropriation of payments refers to the application of a payment made to a creditor by his debtor, to one or more of several debts. The debtor has the first right of appropriation. No precise words are required of him, his intention when made known being sufficient, but such facts must be proved as will lead a jury to infer that he did intend to make the specific appropriation claimed. An entry made by the debtor in his own book at the time of payment is an appropriation if made known to the creditor, but otherwise if not made known to him. The same rule applies to a creditor's entry communicated to his debtor. If the debtor does not apply the payment, the creditor may do so. There are, however, some restrictions upon this right. The debtor must have known and waived his right to appropriate. Hence an agent cannot always apply his principal's payment. He cannot, upon receipt of money due his principal, apply the funds to debts due himself as agent, selecting those barred by the statute of limitations. A creditor having several demands may apply the payments to a debt not secured by sureties, where other rules do not prohibit it. The court will direct the application of a payment upon the failure of both debtor and creditor to do so. Payments made on account are first to be applied to the interest due thereon at the time of payment, and if the payment exceed the amount of interest, the balance goes to extinguish the principal. 3 Sandf. Ch. N. Y. 608; 11 Paige Ch. N. Y. 619. Funds must be applied by the creditor to a judgment bearing interest, in preference to an unliquidated account. When no other rules of appropriation intervene, the law applies part-payments to debts in the order of time, discharging the oldest first. The general rule is that neither debtor nor creditor can so apply a payment as to affect the liability of sureties without their consent. Where a principal makes general payments the law presumes them, *prima facie,* to be made upon debts guaranteed by a surety rather than upon others, although circumstances and intent will control this rule, as they do other rules of appropriation. 5 Leigh, Va. 329. Payments upon continuous accounts are applied to the earliest items of account unless a different intent can be inferred. 5 Metc. Mass. 268; 23 Me. 24; 3 Sumn. C. C. 98. Where a creditor of an old firm continues his account with the new firm, payments by the latter will be applied to the old debt, *prima facie,* the preceding rule of continuous accounts guiding the appropriations. A different intent, however, clearly proved, will prevail. The appropriation cannot be changed, when once made, but by common consent, and rendering an account and bringing suit declaring in a particular way is evidence of an appropriation. 9 Paige, Ch. N. Y. 165.

Approx'ima'tion, a term in mathematics signifying a continual approach to a quantity required, when no process is known for arriving at it exactly. Although, by such an approximation, the exact value of a quantity cannot be discovered, yet in practice it may be found sufficiently correct; thus the diagonal of a square whose sides are represented by unity is $\sqrt{2}$, the exact value of which quantity cannot be obtained; but its approximate value may be substituted in the nicest calculations. This process is the basis of many calculations in pure and applied mathematics, and is of frequent use and great importance in all practical operations.

Appur'tenance, in legal phraseology anything belonging to another thing as principal, and which passes as incident to the principal thing. 10 Pet. U. S. 25; 1 Serg. & R. Pa. 169. For instance, if a house and land be conveyed, everything passes which is necessary to the full enjoyment thereof and which is in use as incident or appurtenant thereto. If a house is blown down, a new one erected there shall have the old appurtenances. 4 Coke 86. The appurtenances of a ship include whatever is on board of it for the objects of the voyage and adventure in which she is engaged, and which belong to her owner.

Aprax'ia, a term denoting a loss of power to appreciate the use and nature of common objects. Thus a patient with this affection might try to comb his hair with a tooth-brush or blacken his boots with a dinner-plate. It is a purely psychical disorder and frequently accompanies aphasia.

Apraxin, a-präks'ĭn, **Feodor Matejevitch,** a Russian admiral: b. in 1671; d. in Moscow in 1724. He may be considered as the creator of the Russian navy and was the most powerful and influential person at the court of Peter the Great, who made him chief admiral. In 1708 he defeated the Swedish general Lübecker in Ingermannland and saved the newly built city of St. Petersburg from destruction. In 1713 he took Helsingförs and Borgo and defeated the Swedish fleet. He was twice fined for embezzlement, but, being too useful to be dispensed with, Peter, in both instances, neutralized the effects of the condemnation by conferring upon him additional riches and dignities.

Apraxin, a-präks'ĭn, **Stepan Fedorovitch,** a Russian general, grandson of F. M. Apraxin (q.v.): b. in 1702; d. in 1760. He defeated the army of Frederick the Great at Gross-Jägerndorf in 1757, but, omitting to follow up his victory by proceeding to Berlin, was tried by court-martial, but died before sentence was pronounced.

Apricot, a small tree (*Prunus armeniaca*), of the natural order *Rosaceæ*, long grown for its fruit and supposed to be a native of China, whence it reached Europe by way of western Asia in the time of Alexander the Great. The fruit resembles the peach in form, color, and its downy skin, and has a large, smooth, or slightly furrowed plum-like pit. It usually ripens earlier than either the peach or the plum. The choice varieties, of which, considering the length of time that it has been in cultivation, there are comparatively few, are firmer, less juicy, but probably higher flavored than the peach. The tree is plum-like in leaf and habit and peach-like in bark. The apricot demands practically the same general management and is as hardy as the peach and succeeds in similar climates and situations.

Eastern Apricot Growing.— Though grown to some extent in the eastern United States, the apricot has not become widely popular for four principal reasons: its susceptibility to injury from late spring frosts which destroy the very early appearing blossoms; the attacks of its special enemy, the curculio (see PLUM); incomplete knowledge of suitable stocks upon which to work it so as to ensure its most perfect growth in various soils, etc.; and ignorance of its dessert qualities, probably owing to the lack of systematic exploitation by nurserymen. Best results seem to be obtained upon the deep, dry, gravelly loams suited to the apple, where such lands are situated on the leeward side of large bodies of water or elevated and facing the north. The trees are usually set 20 feet apart and cultivated like the peach, but since the fruit-bearing habit is similar to that of both the plum (on spurs) and the peach (on wood of the previous season's growth), pruning resembles most nearly that of the plum. When properly managed and grown under favorable conditions the apricot probably equals the peach in productiveness, but like other tree fruits the fruit must be systematically thinned to obtain specimens of good size and to prevent bearing in alternate years. Since the apricot is even more a dessert fruit than the peach and must be carefully grown, picked, packed, and marketed, only the most careful Eastern fruit growers attempt its extensive cultivation. The chief disease, leaf-spot, is treated under PEACH.

California Apricot Growing.— Though the apricot has been known in California for more than a century in the vicinity of the Missions, where it was grown mainly from seeds, it has become commercially important only since American occupancy, in the early years of which improved varieties were introduced from Europe. In the Old World these varieties were trained to walls and otherwise coddled; in California they require no such treatment. As a consequence the apricot has become a leading fruit of the State where in 1899 more than 40,000 acres were devoted to this crop. The world-wide demand for the fruit, fresh, dried, canned, and candied, is fostering still wider planting, and California, already the greatest apricot-growing region of the world, seems destined to be still greater. The tree is found to succeed well on the higher ground of interior valleys upon a variety of soils, but, as in the East, is susceptible in the low ground to injury by late spring frosts. For detailed account of California apricot-growing, consult Bailey 'Cyclopedia of American Horticulture,' (1900–2).

A Priori («from what goes before»), a phrase applied to a mode of reasoning by which we proceed from general principles or notions to particular cases, as opposed to *a posteriori* («from what comes after») reasoning, by which we proceed from knowledge previously acquired. Mathematical proofs are of the *a priori* kind; the conclusions of experimental science are *a posteriori*. It is also a term applied to knowledge independent of all experience.

Apsides, ăp'si-dēz (the plural of *Apse* or *Apsis*), an astronomical term designating the two points in the elliptic orbit of a planet where it is at the greatest and the least distance respectively from the body around which it revolves. The moon moving in an elliptic orbit around the earth, which is situated in one of the foci, is at what was anciently called its higher apse when in apogee, and at its lower one when in perigee. Similarly, the primary planets, including the earth and some of the comets, moving in elliptic orbits around the sun, which is situated in one of the foci, pass through their higher apse when in aphelion, and their lower one when in perihelion. It is the same with the satellites of Jupiter when they are farthest from Jupiter and nearest to it.

The line of the apsides is the line connecting the two apsides of a primary or secondary planet.

The progression of the moon's apsides is a slow movement in the position of the apsides of the moon, produced by the perturbing attraction of other heavenly bodies. It is about three degrees of angular motion, in one revolution of the moon, and in the same direction as her progression in her orbit. The apsides of the primary planets are also perturbed.

Ap'sley Strait, a narrow channel between Melville and Bathurst Islands, off the north coast of Australia. It is about 40 miles in length, with a breadth varying from 2 to 5 miles. The land is low on either side, and the shores bordered by a broad belt of impenetrable mangroves, and indented by numerous salt-water creeks, which present the appearance of rivers. Alligators of enormous size abound in the Straits, many of them measuring from 14 to 17 feet in length. A settlement was formed in 1824, on the Melville Island side of the channel, about 8 or 10 miles from its northern entrance, but subsequently abandoned.

Ap'teryx, a strange flightless bird of New Zealand, representing the *Apteryges*, a group of ratite birds nearly related to the extinct dinornis. Four or five species are known in the various islands of the New Zealand group, besides two fossil species. These curious birds, called "kiwis" by the natives, are about the size of domestic fowl and have very stout legs, wings reduced to a mere useless stump, long snipe-like beaks, and no visible tail. The plumage is colored in streaked browns and grays, and the feathers are incomplete, the disunited filaments giving them the appearance and feeling of coarse hairs. Kiwis inhabit the forested hills, going about in small flocks which during the day hide in the thickets or in cavities of the ground or rocks. They sleep during the bright part of the day rolled up into a ball, but sometimes rest for a long period in a standing position, with the point of the bill touching the ground, as though they were leaning upon it. Their feeding-time is in the dusk of early morning and at evening, and their diet consists chiefly of worms, which they search for apparently mainly by the sense of smell, and obtain by probing the ground with their long bills. The nostrils are at the tip of the beak, which is also flexible and extremely sensitive to the touch, so that a worm may be detected when it is touched, although the bill may need to be thrust its whole length into the ground. The nest is usually at the end of a round tunnel dug in soft earth by the female, and consists of a little dry fern or a few leaves. The eggs, generally two in number and incubated mainly by the male, are remarkable for their size, since they are equal to a quarter of the mother's weight. They are greenish white in color with a smooth surface. As might be expected from the size of the egg, the development of the young reaches a high degree of maturity before hatching. The Maories are very fond of the flesh of the kiwi, either roasted or boiled, and their persistent hunting had greatly decreased the number of the birds before white men reached the islands. Since that time dogs and other accompaniments of civilization have nearly exterminated these birds, which are the sole survivors of the moas. The most complete description of their habits will be found in Buller's 'Birds of New Zealand' (second edition, 1888). For anatomical details and relationships see Parker's memoirs in the 'Philosophical Transactions' for 1891 and 1892. A good summary of this information will be found in Newton's 'Dictionary of Birds' (1896). See DINORNIS; MOA.

Ap'thorp, William Foster, an American dramatic and musical critic: b. in Boston, Mass., 24 Oct. 1848. He was graduated from Harvard University in 1869 and pursued his musical studies under J. K. Paine and B. J. Lang. He taught in the New England Conservatory and College of Music to 1884, was musical critic for the 'Atlantic Monthly' 1872–6; the Boston *Sunday Courier* 1876–8; and the *Evening Traveler* 1878–80. He has been musical and dramatic critic for the Boston *Evening Transcript* since 1881, and was the critical editor of Scribner's 'Cyclopædia of Music and Musicians.' He has written 'Hector Berlioz' (1879); 'By the Way'; 'Music and Music Lovers'; 'Opera, Past and Present.'

Apule'ius, or **Appuleius, Lucius**, a satirist and philosopher of the 2d century: b. at Madaura, in Numidia; the time of his death is unknown. He was author of the celebrated satirical romance called the 'Golden Ass.' He first studied at Carthage, then renowned as a school of literature, and afterward went to Athens, where he became an ardent follower of the Platonic philosophy. Falling ill while on a journey he was hospitably received in the house of Sicineus Pontianus, a former fellow-student, whose widowed mother Apuleius married. Soon after Pontianus died, and the relatives of the rich widow publicly accused Apuleius of having used magical arts to gain her love. The speech by which he successfully defended himself, 'Apologia sive Oratio de Magia,' is still extant. The remainder of his life, which he devoted to oratory and literature, seems to have been passed at Carthage, where, as in some other cities, a statue was erected in his honor. His 'Metamorphoses,' 'Golden Ass,' a romance in eleven books, contains wit, humor, powerful satire, and much poetical merit. It is supposed to have been intended as a satire on the hypocrisy and debauchery of certain orders of priests, on the tricks of pretenders to supernatural powers, and on the prevalent vices generally. The finest part of this work

is the episode of Psyche, called by Herder the most tender and many-sided of all romances. It is sufficient to render him immortal, even if he be, as some have supposed, only the narrator, and not the inventor of the story. Apuleius was also the author of many works on philosophy and rhetoric, some of which are still extant. Cervantes, Le Sage, Boccaccio, and others are indebted to Apuleius for various episodes. See edition of his complete works, Hildebrand (1842); Van Vliet (1897–1900). An English translation by Head was published in Bohn's Classical Library in 1851.

Apu'lia, a province of southern Italy, composed of the provinces of Foggia, Bari, and Lecce; area, 8,539 square miles; pop. (1901) 1,949,425. The northern part forms the Apulian Plain, a rather barren tract on the whole, although affording extensive sheep pastures and isolated spots capable of cultivation, on which wine, olives, southern fruits, and maize are grown. The surface of the plain is not quite level, but diversified by broad undulations crossing one another at right angles. The southern portion is traversed from west to east by low ranges of hills. In the extreme northeast of this part of the province rises close to the sea the isolated mountain Gargano, which attains the height of nearly 5,000 feet. The most important river is the Ofanto (Aufidus). There are four coast-lakes of considerable size. Lake Salsi dries up in a great part in summer; and on its banks are the great salt-boiling works of Barletta. There is a considerable trade in grain, oil, salt, southern fruits, cattle, wool, etc. Apulia was in ancient times inhabited by several peoples, such as the Apuli, Messapii, and Daunii. It was subdued by the Romans in 317 B.C.

Apure, ä'poo-rā', a river in Venezuela, formed by the junction of several streams issuing from the Sierra de Merida. After an eastern course of about 300 miles it falls into the Orinoco at Capuchino. It is navigable throughout almost its entire course.

Apurimac, ä-poo'rē-mäk', the name of a department of Peru, embracing a territory of 8,187 square miles and lying between the departments of Cuzco and Ayacucho. Its capital is Abancay. Pop. (estimated, 1902) 178,000.

Apurimac, a Peruvian river in South America, the outlet of a lake in the Andes of Peru, in the province of Arequipa, not far from Caylloma. It is probably the tributary of the Amazon rising nearest the Pacific Ocean. It flows through a mountainous country in a northerly direction, and, joining the Yucay or Vilcamayu at lat. 9° 15′ S.; lon. 72° 30′ W., forms the Ucayale, one of the principal tributaries of the Amazon. Its entire extent is between 500 and 600 miles.

A'pus, a name designating a fresh-water phyllopod crustacean, remarkable for having 47 body-segments, 20 being the normal number in *Crustacea*. It also has 60 pairs of limbs, certain segments bearing as many as six pairs of legs, the normal number in all arthropods being no more than a single pair to a segment. The body is protected by a large carapace resembling that of the king-crab (q.v.) in that it is adapted for burrowing in soft mud at the bottom of lakes or pools. Apus is locally distributed over western North America, Asia, and Australia. One form (*Lepidurus glacialis*) lives in pools in the Arctic regions. It undergoes a complete metamorphosis, its larva being a "Nauplius" (q.v.). The family (*Apodidæ*) appears to be of high antiquity, since the impression of an obscure crustacean (*Protocaris*), generally referred to it, has been detected in the lower Cambrian rocks of Vermont. See Packard, 'Monograph of North American Phyllopod Crustacea' (1883); Bernard, 'The Apodidæ' (1892). See PHYLLOPODA.

A'qua (Latin, water), a word used by the alchemists and early chemists for solutions or other fluid preparations in which the menstruum is water. *Aqua ammoniæ* ("ammonia water") is an aqueous solution of ammonia gas (NH_3). *Aqua fortis* ("strong water") is nitric acid. *Aqua regia* ("royal water") is a mixture of nitric and hydrochloric acids, the name (bestowed by Basil Valentine) referring to its power of dissolving gold and other so-called noble metals. *Aqua vitæ* ("water of life"), so-called by Avicenna, is common grain alcohol. The word "aqua" is still in general use in pharmacy for designating aqueous solutions or infusions.

A'quæ So'lis, the ancient Roman name of the modern English city of Bath. It was famed for the splendor of its buildings and its many springs, and the remains of several Roman baths have been discovered here.

Aquamarine, ă-kwa-ma-rēn' (from the Latin *aqua marina*, "sea water"), a bluish-green variety of beryl (q.v.) esteemed as a gem. Siberia and Brazil have long been celebrated localities, while magnificent gem material has lately been mined in North Carolina.

Aqua'rians, a name applied to Christian ascetics in the primitive Church, who consecrated water instead of wine for the celebration of the Lord's Supper — either for the sake of abstinence, or because they thought it unlawful to drink wine.

Aqua'rium (Latin, a watering-place for cattle, from *aqua*, water), a term applied to a tank or smaller receptacle filled with water and stocked with aquatic animals and plants for study, or, in the smaller examples, for mere beauty and interest. To maintain natural conditions, both plants and animals must be present — the plants to give off oxygen for the animals, as well as to furnish food for many of them, and the animals to supply carbonic acid to the plants. Unless there is some arrangement for constant or frequent renewal of the water, it should often be aërated. Dipping it up and pouring it in again from a height will do this, if there is no less primitive way. The aquarium is provided with sea water or fresh water according as marine or fresh-water life is to be kept; when it is difficult to secure sea water for a marine aquarium, one may prepare a substitute by dissolving common salt, epsom salts, and certain other salts in the proper proportions in fresh water; but, when thus artificially prepared, salt water is not fit for the reception of animals until certain plants, particularly species of *Ulva*, a genus of green algæ, have lived in it. With aëration and the removal of any dead animal or rotting plant, the water may be kept in good condition for a

1 and 2. BALANCED AQUARIA

3. MAIN HALL OF NEW YORK AQUARIUM

long time if supplied with a number of mollusks for the consumption of the too abundant growth of the algæ and of their spores, which, otherwise, soon fill and discolor the water. When aquaria are placed in insufficient light, noxious fungi sometimes develop in them, doing injury to the other inmates. Fresh-water fishes in particular are subject to fungous parasites which attack their eyes, gills, or any chance wound. They may frequently be cured by a bath in a strong solution of common salt, which affects them severely, but from which they recover if washed in an abundant stream of fresh water. The large public aquaria which exist in many cities are a great aid to students and a constant source of entertainment to the people. In America the aquarium of the United States Fish Commission at Washington and the New York city Aquarium are most important. The latter is under the control of the Department of Parks and was established in 1897 in old Fort Clinton (known for many years as Castle Garden) on the Battery. It is entirely free and has a daily average of 4,000 visitors; both marine and fresh-water animals are exhibited. In the floor are seven large pools, and the wall tanks number nearly 100. All the arrangements are the best which experience has yet suggested, and opportunities for special study of ichthyology and the natural history of marine animals are afforded. In Europe the aquarium at Brighton, England, and particularly that connected with the Marine Laboratory at Naples, are of the greatest interest and importance. The most recent American work on the construction and management of an aquarium is G. E. Smith's ‹The Home Aquarium.› For information upon the sea-animals suitable for keeping in a marine aquarium consult Verrill, ‹Invertebrates of Vineyard Sound,› in the annual reports of the United States Fish Commission for 1871–2.

Ernest Ingersoll,
Editorial Staff, ‹Encyclopedia Americana.›

Aqua'rius (the water-bearer), in astronomy, (1) the 11th of the twelve ancient zodiacal constellations, now generally called signs of the Zodiac. (2) A division of the ecliptic — that between 300° and 330° of longitude, which, on account of the precession of the equinoxes, has gradually advanced from the constellation Aquarius, once within those limits. The sun enters this part of his course about the 21st of January, at which time there are generally copious rains in Italy, whence the name Aquarius = the water-bearer or water-man. (Herschel's ‹Astronomy,› §§ 380, 381.) It is marked thus ♒.

Aquat'ic Animals, a term denoting animals living constantly in water, and also those which swim on its surface or plunge beneath it for food. While the great majority of crustaceans are aquatic, a few, such as the wood-louse and the land crab, are modified for life ashore. Among mollusks there is occurrence of both aquatic and terrestrial habit, while numerous forms illustrate the transition from the former to the latter. The ascidians are exclusively marine. Some fishes have a limited power of life out of the water, the double-breathing *Dipnoi* being in this connection especially instructive. Among many amphibians the transition from water to *terra firma* is seen in the individual life-history, when the fish-like gilled tadpole becomes the lunged gill-less frog; while in a few exceptional cases, such as the black salamander of the Alps, the life is terrestrial from first to last, and even the young dispense with their preliminary swim as tadpoles, although a brief recapitulation of their aquatic life is still represented by a gilled stage within the body of the parent. The instance of the gilled axolotl becoming, in the absence of sufficient water, the gill-less amblystoma, forcibly illustrates the importance of the medium as a factor in evolution. Among reptiles there are numerous aquatic forms,— chelonians, lizards, snakes, and crocodiles,— though the absence of any gill respiration marks the progressive general adaptation to terrestrial life. While an emphatically terrestrial amphibian like the tree-frog seeks a watery hole for the rearing of the young gill-breathing tadpoles, the habit is reversed in such reptiles as the sea turtle, which, having returned to the more primitive aquatic home, yet revisits the land for egg-laying purposes. The cradle of the young in both cases indicates the ancestral habit of the parent. Among the emphatically aërial birds there are cases, like that of the penguin, where the structure has become adapted to an almost exclusively aquatic life. Among mammals, the sea-cow, the seal, and the whale are familiar illustrations of very different types which have returned to the primeval watery home and aquatic habit, with consequent change of structure.

It is important to note the general fact that, in the water, animals are subjected to influences somewhat different in detail from those which mold their congeners ashore. Even contact with a different medium, varying in composition, in currents, in pressure, in contained food and oxygen, and the like, obviously involves a great diversity in structure. Modes of motion, from the swimming-bell of a medusoid contracting and expanding in the tide, to that of the lowest vertebrates as illustrated in the pelagic tunicates, or from the paddling of worm and crustacean to that of fish and frog, duck and seal, are at once familiar adaptations to, and necessary results of aquatic life. Similarly the smooth and frequently fish-like form, especially of actively locomotive water-animals, is a very noticeable adaptive result of the conditions of life. In the more thoroughly aquatic animals, which have remained in the primitive environment, and not merely returned to it, the blood is usually purified by being spread out on feathery gills which catch the oxygen dissolved in the water; while in terrestrial forms which have betaken themselves to an aquatic life, the ordinary direct «air-breathing» is still accomplished at the surface of the water, or in some isolated cases of insects and spiders, by means of the air entangled in their hairs, or even conveyed into their submerged homes. The aquatic respiration of some larval insects, the power that some crustaceans and fishes have of keeping up a respiration on land with a minimum of water about their gills, and, above all, the cases of the double-breathing fishes or *Dipnoi*, and of amphibians already referred to, are especially instructive in regard to the problem of transition from one medium to the other. The genuinely aquatic animals are known to have a body temperature not much higher than that

of the surrounding medium, and often survive even the freezing of the water; while in the higher warm-blooded vertebrates which have returned to an aquatic habit, various modifications, such as thick fur and plumage, waterproof varnish, formation of blubber, serve as protections against the cold.

Aquat'ic Plants, a term applied to plants growing in or belonging to water. All vegetation was probably aquatic at first, certain plants becoming terrestrial by degrees. Numerous plants are, moreover, in the strict sense of the word aquatic, having never acquired or having lost all direct connection with the soil. The algæ are mainly aquatic, though many occur in damp situations on land, or on other organisms, while others remain for long periods quiescent in comparative dryness. Many algæ are absolutely isolated in the water, while others are more or less intimately fixed to some solid substratum. Fungi are very seldom found in water, and lichens are also emphatically terrestrial. Some liverworts, again, occur floating in lakes, but the majority grow in very damp places and mark the transition to the generally terrestrial life of mosses and ferns. Some rhizocarps, such as *Salvinia*, are aquatic, with leaves rising to the surface, while others are land or marsh plants, like the higher horse-tails and club-mosses.

Among the flowering plants, or phanerogams, a return to aquatic life is exhibited by numerous though exceptional cases, while a very large number grow in moist situations and have a semi-aquatic habit. The simple monocotyledons, known as *Helobiæ*, or marsh lilies, are more or less strictly water-plants. The arrow-head (*Sagittaria*), and other *Alismaceæ;* the *Butomis* of the marshes; *Hydrocharis*, with floating kidney-shaped leaves; the water-soldier (*Stratiotes*), with narrow submerged leaves; and the Canadian pond-weed (*Anacharis*), which, though entirely flowerless in Europe, threatens to choke some canals and lakes, are familiar representatives. The little duck-weed (*Lemna*), floating on the surface of stagnant pools, is one of the commonest aquatic monocotyledons; and the pond-weeds (*Potameæ*) found in both fresh and salt water: the lattice-plant (*Ouvirandra*), with its skeleton leaves; various estuarine and fresh-water naiadaceous plants,— for example, *Zostera* and *Naias*, are also common instances, while those growing in marshy ground are far too numerous to mention. Among dicotyledons the white water-buttercup (*Ranunculus aquatilis*), with its slightly divided floating and much dissected submerged leaves; the yellow and white water-lilies (*Nymphæa*); the sacred lotus flower of the Ganges and Nile (*Nelumbium*); the gigantic *Victoria regia* of tropical South America; and the insectivorous bladderwort or *Utricularia*, are among the more familiar aquatic forms.

A'quatin'ta, the name given to a method of engraving or etching upon copper or steel, invented by Leprince in 1760. The outline of the subject having been etched and bit, the plate is thoroughly cleansed, and a thin layer of etching ground is again spread over it. When dry, the parts of the subject to be aquatinted are carefully painted over with a mixture of olive oil, turpentine, and lamp-black; this fluid, laid on with a hair pencil, quickly dissolves the parts of the ground it covers, which are then wiped off. The plate is next dusted all over with a finely-powdered white resin or mastic, and when equally distributed the superfluous resin is shaken off, and the plate gently heated over a charcoal fire till the resin dissolves and adheres to the bare metal. In dissolving, the grains of the resin run into small granules, leaving minute and peculiarly shaped portions of the metal open to the action of the aquafortis, a weak solution of which is then poured over the plate. When corroded to the proper strength the subject has acquired what may be termed the first wash of color. The plate is then cleaned, re-covered with ground, and treated as before, for the second tint. The process is repeated until all the deeper tones of shading are completed. These operations are sometimes reversed, the darkest shades being first bit in, and the lighter ones added by degrees.

Aq'ueduct, a term denoting an artificial channel or conduit for the conveyance of water from one place to another; more particularly applied to great architectural structures for conveying water from distant sources for the supply of large cities, until the recent development of water-ways on a large scale for irrigation, mining, and power has brought this term into more general use. Works for supplying communities with water must have been constructed at a very early period. In China there are said to be aqueducts dating back to prehistoric times. In Persia and Assyria there are structures whose remains indicate that they were used for aqueducts, but their history is not clear. Recent excavations at Jerusalem have laid bare wells and channels cut in the solid rock, and indicate that the water supply of the city was brought from the neighborhood of Bethlehem and Hebron. These channels seem to have been composed of earthen pipes incased in stones and covered with rough rocks cemented together. It is supposed that King Solomon built aqueducts; others are ascribed to Rameses the Great, in Egypt, and to Semiramis in Assyria. There are also early remains at Palmyra in the wilderness. In the island of Samos have recently been discovered remains of a tunnel nearly a mile long and containing water-pipes about nine inches in diameter. These may have been built in 687 B.C. by Eupalinos of Megara. Water was brought to Athens from Mount Hymettos and Mount Pentelikon; Thebes, Megara, Pharsalos, and other places also had aqueducts. In Patara, a city of Lycia, in Asia Minor, there is a very ancient aqueduct consisting of an embankment of rough stone 250 feet high and 200 feet long, with an archway at the centre of the valley, allowing the stream to pass through it underneath. The channels for the water consist of cubical stone blocks about a yard in dimension, with a hole 13 inches in diameter, the blocks being closely connected and cemented together.

Roman Aqueducts.— While the Greeks developed underground water-ways and canals, and followed simple methods, the Romans under their great engineers produced massive structures for carrying water at a high level across valleys and plains. At first Rome was satisfied with water from the Tiber, from wells, and the abundant springs which gushed forth within its precincts. Four hundred and forty-two

years preceded the first aqueduct, which was the joint work of Appius Claudius Cæcus and Caius Plautius Venox, censors in 312 B.C. Appius Claudius built the conduit, Venox discovered the springs. The entire length of the aqueduct was 16,445 metres, or about 10 miles, and it furnished 115,303 cubic metres a day. The second aqueduct was begun in 272 B.C. by Manius Curius Dentatus, and was finished three years later. Its length was 63,704 metres, or about 45 miles, and it furnished 277,866 cubic metres a day; it was not used for drinking, but for irrigating gardens and flushing drains. In 144 B.C. the Senate determined to repair the two old aqueducts and build a new one. This work was begun by Quintus Marcius Rex. The Marcian aqueduct brought the water from 36 miles away in the territory of Arsoli, and fed water to the highest platform of the capitol. It was restored in 33 B.C., and Augustine doubled the supply of water in 5 B.C. In 79 A.D. Titus repaired it; in 196 Septimius Severus brought in a new supply for his baths; in 212–3 Caracalla cleaned out the springs, added a new one, and restored the aqueduct, building a branch four miles in length for his baths; in 305–6 Diocletian performed the same service. The viaducts and bridges by which it crossed the highlands are magnificent. There are seven bridges, some of them carrying four aqueducts. The Marcian reaches Rome at the Porta Maggiore, where no less than 10 water supplies met. It was restored as recently as 1869 and brings a water supply from the Sabine Mountains. The noble arches which stretch across the Campagna for some six miles on the road to Frascati are a portion of this aqueduct. The Aqua Tepula and Aqua Julia, combined by Agrippa in 33 B.C., had a length, the one of 17,745 metres, or 10 miles, the other of 22,853 metres, or about 12 miles, and a combined flow of 104,300 cubic metres a day. Of the nine aqueducts which brought water to ancient Rome, three still supply the modern city, namely, the Aqua Virgo, now Acqua Vergine, finished by Agrippa, 27 B.C., and restored by Pope Nicholas V. in 1453; the Aqua Trajana, now Acqua Paolo; and the Aqua Marcia.

The Romans also constructed important aqueducts for the cities throughout their empire. In 120 A.D. the emperor Hadrian constructed the aqueduct of Saghuan, which supplied Carthage with water, bringing it by arched bridges of stone or concrete about 60 miles. This aqueduct still supplies Tunis with water. Hannibal is said to have erected an aqueduct at Martorell, in Spain. The aqueduct of Alcantara, also in Spain, stretches over the Tajo, and is 125 feet high, with a span of over 100 feet. There are other Spanish aqueducts at Chelves, at Merida, over the Albareges, and at Segovia. That at Segovia was originally built by the Romans, has in some parts two tiers of arcades 100 feet high, is 2,921 feet in length, and is one of the most admired works of antiquity. The one at Evora, in Portugal, is still in excellent condition. One of the finest aqueducts in Europe is the Pont du Gard, built in the 3d or 4th century, or possibly by Agrippa, 19 B.C., at Nimes, in southern France. It is still in a good state of preservation. It is higher than any about Rome itself, being fully 180 feet in height, and the length of its highest arcade is 873 feet. It is composed of three tiers of arches, each less wide than the one below, and is admirably constructed of large stones, with no cement used except for the canal on the top. There is an aqueduct at Paris, built by Julian in 360 A. D., also a very important aqueduct at Constantinople, built by Hadrian and restored by Theodosius. Since 1885 the water has been furnished the city by an aqueduct built by a French company, taking the supply from Lake Derkos, whence the water is pumped 358 feet into a reservoir. The ruins of an aqueduct exist at Mayence, and those of another near Metz, Germany. The aqueduct at Spoleto, Italy, is attributed by some to the East Gothic king Theodoric, in 500 A. D., and by others to Theodelapius, the third Duke of Spoleto, 604 A.D. It is built of brick and rests between two steep cliffs on 10 arches, and is 290 feet in height and 231 yards in length. The ground plan is apparently Roman, while the pointed arches indicate a restoration in the 14th century. Many important aqueducts are found in more recent times. One of the most remarkable is that constructed by Louis XIV., in 1684, to convey the waters of the Eure from Point Gouin to Versailles. Troops to the number of 40,000 were employed in this great undertaking. Thousands of these men died during the progress of the work, which was interrupted during the war of 1688 and never resumed. The bridge at Maintenon, forming part of this aqueduct, even in its incomplete state is, in point of magnitude, the grandest structure of the kind in the world. The remains consist of 47 arches, each 42 feet wide and 83 feet high. The piers are 25 feet 6 inches thick.

The first important aqueduct in England was built in 1613, to conduct the waters of the New River to London, over a distance of 20 miles. Wooden aqueducts were first used, but were replaced by embankments. Very large works were constructed during several years, ending in 1877, to bring water from Longdendale, between Sheffield and Manchester, to the latter city. In this instance the aqueducts consist for the most part of tunnel and covered conduit, but for eight miles the water is conveyed in large cast-iron pipes laid along or under the public roads. Before the Longdendale works were finished the question of a greater supply had to be considered. This led to the adoption of the scheme for bringing water from Lake Thirlmere in Cumberland to Manchester. The length of the line is nearly 100 miles, and the works were carried out in 1885–94. A tunnel, about three miles in length and 270 feet below the surface, forms the first part of the aqueduct. There are 13¾ miles of tunnels, 38 miles of shallow tunnels cut from the surface, and 44½ miles of siphon pipes of 40 inches diameter. The aqueduct passes under Dunmail Raise, north of Grasmere, Ambleside, Windermere, and Kendal, to the east of Lancaster and Preston, across the Rivers Lune and Ribble, past Chorley, and west of Bolton. The ultimate supply is 50,000,000 gallons daily; the cost, $21,500,000. In Scotland, the Loch Katrine aqueduct supplies Glasgow with water coming from a distance of 26 miles. An aqueduct was built in 1738, conducting water for a distance of about nine miles into the city of Lisbon. For a part of the way it is underground, but near the city

is carried over a deep valley for a distance of 2,400 feet, on several arches, the largest of which has a span of 115 feet, and is 250 feet high. The aqueduct of Caserta, in Italy, was built in 1573 by Vanvitelli, for the purpose of supplying the gardens of Caserta with water from Monte Taburno, a distance of 25 miles. It now conducts the water to Naples and crosses 20 valleys; the last 15 miles the water is carried in iron pipes. The Canal de Marseilles, in France, is 57 miles in length. It conveys water from the River Burance to Marseilles, and is a magnificent specimen of engineering. It was finished in 1847. At Roquefavour it crosses a valley on a bridge, the length of which is 1,290 feet. The Vienna aqueduct, nearly 60 miles long, was finished in 1873. At several places in its course there are extensive aqueduct bridges, built either entirely of stone or of stone and brick. This aqueduct supplies 20,000,000 gallons of water per day. In America are a number of important aqueducts. For 125 years the city of Otumba, in Mexico, received its supply of water through the aqueduct of Zempoala, a canal 27 miles long, which, though said to be in almost perfect condition, has not been used since 1700. New York is supplied with water from the Croton River, which falls into the Hudson above Sing Sing. The first aqueduct, which was constructed between the years 1837 and 1842, at a cost of $12,500,000, is 38 miles long with a general declivity of 13¼ inches to the mile, and is eight feet five inches in height, and seven feet eight inches in greatest breadth. Stone, brick, and cement are used for the encasing masonry. The conduit, where it crosses the Harlem River, was carried in iron pipes over a splendid bridge 150 feet above the river. Although an important and well-executed work this aqueduct was soon found to be inadequate for the greater city, and a new and larger reservoir and aqueduct were put into service in 1890. The water-way is 33 miles long, 29 of which lies in a tunnel through rock, where a horseshoe-shaped brick, or stone and cement conduit 13½ feet high is constructed. At the Harlem River this water is carried through an inverted siphon 300 feet beneath the river. The siphon has been used also to carry water under the Danube at Nansdorf, Germany. It replaces the old Roman arched water-way and is possible since the system of building ceiled conduits has come into general use. The first aqueduct for supplying Boston with water was built in 1846–8, 30 years later an aqueduct was built to carry water from the Sudbury River to Boston. This line crosses the Charles River on a large stone arch known as Echo Bridge, and has a fine bridge also in the Waban valley. As the city demanded a still greater supply an immense reservoir was projected to retain 65,000,000,000 gallons of water in the Nashua valley near Clinton, Mass., from which the water is to be conducted to the Metropolitan district of Boston. With this it is said the city will have a supply of 400,000,000 gallons of water daily. The cities on the Great Lakes require a peculiar system for supplying water. Tunnels are built out under the lakes (four miles at Chicago) to secure unpolluted water, and though of simple masonry, are difficult to construct. The great canals, such as the Suez, the projected Panama Canal, and the Chicago Drainage Canal are really aqueducts. The latter was completed in 1899 at a cost of $33,000,000. It carries 300,000 gallons of water per minute from the Chicago River and Lake Michigan to the Illinois River. A unique aqueduct was built in Pittsburg, Pa., in 1845. A canal was suspended from two cables across seven spans of 160 feet each. The demands of irrigation have required the construction of many aqueducts. In the western United States there are thousands of miles of canals, with dams, tunnels, and costly bridges. In British India, where the rainfall is uncertain, the government has constructed the Ganges Canal, which takes the most of the water from that river and distributes it over a vast area. In the development of water-power some large aqueducts have been constructed. At Niagara Falls a canal leading from the falls has been cut in solid rock. In the mining regions, water-ways and flumes are constructed of considerable proportion, but generally of a very temporary character and hardly to be considered as aqueducts. See CANALS; DAMS; FLUMES; IRRIGATION; WATER-POWER; WATER-WORKS.

A'queous Hu'mor, the designation of the transparent lymphatic fluid in the anterior chamber of the eye, or that portion of the interior of the eye in front of the crystalline lens. In its chemical composition aqueous humor closely resembles the cerebro-spinal fluid. It is a clear alkaline liquid, specific gravity, 1003–1009, and contains about one per cent of solids, one tenth of which are proteids. These are fibrinogen, serum albumin, and serum globulin. Traces of urea and sarcolactic acid are present. The secretion of aqueous humor is rapid. It is supposed that this fluid is derived from the posterior surface of the iris and the ciliary body. See EYE.

A'queous Rocks, the title of a petrographic division including all rocks that have been deposited under water. It is the most important class of the sedimentary series, and comprises such common and widely distributed strata as sandstones, conglomerates, shales, and limestones, and many valuable products, as gypsum, salt, and coal. According to their manner of origin the aqueous rocks may be subdivided into (1) mechanical deposits, (2) chemical precipitates. (3) organic accumulations. The mechanical deposits have been derived from the disintegration of pre-existing strata and the transportation of the materials by rivers, tides, and currents. They are being formed at the present time beneath the ocean and in rivers and lakes. Sandstone, conglomerate, clay, shale, and marl are the most important members of this subdivision. The chemical precipitates owe their origin to the deposition of materials from solution either as a result of evaporation or by the action of precipitating agencies. Oölitic limestone, gypsum, rock salt, siliceous sinter, and many iron ores are included in this subdivision. The organic accumulations have been formed from materials once belonging to living organisms. Limestones and chalk represent the comminuted and compacted remains of shells, corals, crinoids, foraminifera, etc., while certain organisms secrete silica, and their casts have accumulated in the form of infusorial earth, chert, and fluid. Peat and the different varieties of

coal are deposits of vegetable matter which has been more or less completely transformed into carbon under the influence of pressure and sometimes also of heat.

Aquifoliaceæ, ă'quĭ-fō-lĭ-ā'cē-ē, the designation of a natural order of plants, composed of shrubs with alternate or opposite persistent leaves, of thick texture and smooth surface, with a toothed margin, the teeth being sometimes spinous. The flowers are solitary, or variously grouped in the axillæ of the leaves. The fruit is always fleshy, containing from two to six indehiscent woody or fibrous nucules or minute nuts enclosing single seeds. The American holly, *Ilex opaca*, has foliage less glossy, and berries less red than its European relative, *Ilex aquifolium*. Both are important commercially, being mostly used for decorative purposes. The genera are *Ilex, Cassine, Myginda.* The leaves of a species of *Ilex* afford the famous Paraguay tea. But one member of this order is found in Europe, the common holly (*I. aquifolium*). The other members are found sparingly scattered over different parts of the world, especially the West Indies, South America, and the Cape of Good Hope. The Latin *Ilex*, the holm-oak (*Quercus ilex*), belongs to a different natural order from the holly, and to the same order as the oak (*Corylaceæ*).

Aquila, ä'kwe-la, one of the early Christians associated with Saint Paul, was of Jewish origin and a native of Pontus. In the year 52, he with other Jews, was expelled from Rome by an edict of Claudius. He and his wife Priscilla went to Corinth, where they first became acquainted with Saint Paul. The apostle shared their lodgings, at the same time assisting them at their trade of weaving tent cloth. He was indebted to them for many acts of kindness and none of the Christians who aided him ever received such warm praise from his pen. See Epistle to the Romans xvi. 3. There are many references to Aquila in the New Testament: Acts xviii. 1–3, and 26–28; 1 Corinthians xvi. 19; 2 Timothy iv. 19. Nothing definite is known about the death of Aquila. Though he led a poverty-stricken life in Corinth and Ephesus, better days came to him; for in the year 58 we again find him in Rome, where he and Priscilla kept a house on the Aventine, large enough to be used as a sanctuary by the Christians of Rome, to whom it was always open. Consult: Fouard's 'Saint Paul and His Missions' (Chap. vii.) and 'Saint Peter and the First Years of Christianity' (Chap. xviii).

REV. JAMES HIGGINS, D.D.,
Long Island City, N. Y.

Aq'uila, Johann Kaspar, a celebrated German Protestant theologian: b. in Augsburg in 1488; d. 12 Nov. 1560. After studying several years in Italy he was appointed pastor of Jenga, a village near Augsburg. Here he embraced the doctrines of Luther; but his boldness and zeal in the cause of reformed faith led the bishop of Augsburg to order his arrest. Aquila passed the winter of 1519–20 in the prison of Dillingen, and from Dillingen he went to Wittenberg, where he became personally acquainted with Luther. He was subsequently appointed professor of Hebrew at Wittenberg, where he rendered valuable assistance to his colleague Luther in his translation of the Old Testament. In 1527 he became pastor, and the following year Protestant bishop at Saalfeld; but his vehement opposition to the *Interim* of Charles V. in 1548 obliged him to flee. He was appointed to the deanery of Schmalkalden in 1550, and restored two years after to his office at Saalfeld, where, without further molestation, he continued to discharge his duties till his death.

Aq'uila, Ponticus, a native of Pontus, who flourished about 130 A.D., and is remembered for his exceedingly close and accurate translation of the Hebrew Scriptures into Greek. See Burkitt, 'Fragments of the Book of Kings, According to the Translation of Aquila' (1897).

Aquileja, ä'kwe-lā'ja, **Aquileia**, or **Aglar**, a town of Austria, 22 miles northwest of Trieste. Before the fall of the Roman empire it was the great emporium of trade between the north and south of Europe, and was often called the "Second Rome." Cæsar Augustus frequently resided here, and several councils of the Church, the first in 381, were held at Aquileja. In the 6th century, the title of patriarch was taken by the bishops of Aquileja, who assumed second rank to the Pope. The town was destroyed by Attila in 452, when the inhabitants numbered 100,000. It is now a small fishing village containing a number of interesting remains of its ancient splendor, and often rewarding the researchers of the antiquary with relics of value. Pop. about 2,000.

Aqui'nas, Thomas, a celebrated scholastic theologian, related by birth to several of the royal families of Europe: b. near Aquino in 1227; d. at Fossanora 7 March 1274. He studied at the Benedictine monastery of Monte Casino and the University of Naples. About the age of 17 he entered a convent of Dominicans, much against the wishes of his family. Partly to evade the endeavors of his family to recover him, and partly on account of the extraordinary aptitude he displayed for theological studies, his superiors sent him to Cologne to hear the lectures of the famous Albertus Magnus. He was so remarkable for taciturnity, and the assiduity and apparent stolidity with which he pursued his studies, that he was known among his fellow-students as "the great dumb ox of Sicily." His teacher, however, discerned his abilities, and is said to have foretold that "this ox would one day fill the world with his bellowings." In 1245 he visited Paris in company with Albertus. Becoming involved in the dispute between the University and the Begging Friars as to the liberty of teaching, he advocated the rights claimed by the latter with great energy, and, being called upon to defend his side in this controversy before the Pope, did so with complete success. In 1248 he returned with Albertus to Cologne, but revisited Paris in 1257, when he received the degree of doctor from the Sorbonne and began to lecture on theology, rapidly acquiring the highest reputation. The remainder of the life of Aquinas was one of the most varied activity. He was almost constantly engaged in lecturing and preaching, and was often sent on distant journeys in the service of his order. In 1263 he is found at the Chapter of the Dominicans in London. In 1268 he was in Italy, lecturing in Rome, Bologna, and elsewhere. In 1271 he was again in Paris lecturing to the students: in 1272 professor at Naples. In 1263 he had been offered the archbishopric of Naples by Clement IV., but refused the offer. A general council being summoned at Lyons in 1274 for the pur-

pose of uniting the Greek and Latin Churches, Aquinas was called thither to present the council with a book which he had written on the subject, but died on the way. The honors paid to his memory were prodigious: besides the title of Angelic Doctor, bestowed on him after the fashion of the times, he was called the Angel of the Schools, the Eagle of Divines, and the Fifth Doctor of the Church; in 1286 he was made by the Dominicans the doctor of their order (*doctor ordinis*); at the request of the Dominicans he was, in 1323, canonized by John XXII., his tomb supplying the necessary testimony of miracles; and 1567 was declared by Pius V. the "Fifth Doctor of the Church." The numerous works of Aquinas are all written in Latin. The most important of them is the 'Summa Theologiæ,' which, although only professing to treat of theology, is in reality designed to form a complete and systematic summary of the knowledge of the time. All the minor works of Aquinas may be looked upon as preparatory to this great one. These are 'A Commentary on the Four Books of Sentences of Peter Lombard'; 'Quodlibeta Disputata et Quæstiones Disputatæ'; the 'Catena Aurea,' or Golden Chain, in form of a commentary on the four Gospels, but in substance an exhaustive exposition of the cardinal doctrines in theology of the greatest fathers of the Church; and commentaries upon Isaiah and Jeremiah, the Epistles of St. John the Divine, and the Psalms, as well as upon Aristotle. His works were published in Rome in 1570–1 in 17 volumes, but his 'Summa Theologiæ' has passed separately through various editions. The resemblance in thinking and writing between Augustin and Aquinas is so marked, that it has been fancifully said that the soul of the one had passed into the body of the other. The disciples of Aquinas are called after him Thomists. See Werner, 'Der Heilige Thomas' (1858); Gibelli, 'Vita de S. Tomaso' (1862); Vaughan, 'St. Thomas of Aquino, his Life and Labours' (1872); Cavanagh (1890).

Aquinas, Saint Thomas, Philosophy of. The philosophy of Saint Thomas Aquinas is the culmination of the philosophic efforts of the Christian schools of the Middle Ages. These schools, dating from their foundation in the reign of Charlemagne, set up a tradition of Aristotelian commentary and of independent speculative activity which, until the middle of the 12th century, were almost entirely circumscribed by the limits of dialectic, or logic. After the middle of the 12th century the physical and metaphysical works of Aristotle (q.v.) became known in the Christian schools of Europe, and with them were introduced Arabian commentaries which interpreted the text of Aristotle in a sense contrary to Christian theism. At the beginning of the 13th century a number of Christian teachers, especially Alexander of Hales and, later, Albert the Great, undertook the task of expounding the theistic and spiritualistic philosophy of the Christian schools on the basis of Aristotle's physical and metaphysical doctrines, rejecting from the current Aristotelian teaching whatever they considered to be due to the influence of the Arabian commentators. These teachers prepared the way for Saint Thomas Aquinas (1225–74), whose chief merit is, not that he created a new method or contributed a new system of thought, but that he gave to the work of his predecessors and contemporaries a more compact synthesis and expounded this synthetic system with a simplicity and lucidity rarely to be met with in systems which like his carry complexity to a high degree of organic unity. Saint Thomas' most important works are the 'Summa contra Gentiles' and the 'Summa Theologica.' The former, begun at Paris about the year 1257 and completed some time between the years 1261 and 1264, was undertaken at the request of Saint Raymond of Pennafort for the purpose of defending the truths of Christianity against the Arabian pantheists and their followers. It is, therefore, apologetic rather than constructive in method and contents. The 'Summa Theologica' was commenced at Bologna in 1271, and was never completed. Unlike the 'Summa contra Gentiles,' it is constructive in aim and method. It is Saint Thomas' greatest work, his last and most important contribution to Christian theology and philosophy; for, although the work is entitled 'Summa Theologica' and is, in fact, a compendious treatise on all the questions of Catholic theology, it is also a summary of philosophy. It begins with the question of the existence of God, treats of the attributes of God, traces the origin of things from God and the return of man to God through Christ. It deals, therefore, with the creation and government of the universe, with the origin and nature of man, with human destiny, with virtues, vices, and laws — with all the great problems of speculative and practical philosophy. It contains the maturer views of its author, so that whenever discrepancies occur between the doctrines of the *Summa* and the views expressed in his earlier works, the *Summa* is to be taken as the key to the mind of the master.

The method used by Saint Thomas in all his constructive works is a developed and perfected form of the dialectic method which we find anticipated in a short treatise by Gerbert (Pope Sylvester II., died 1003) and of which the first definite example is the *Sic et Non* of Abelard (died 1142). In this treatise Abelard presents in contrast the affirmative (*Sic*) and the negative (*Non*) opinions of patristic writers in reference to each successive problem of Catholic theology, without, however, furnishing principles by which the discrepancies, real or apparent, are explained. This was, as far as we know, first done by Alexander of Hales (died 1245), whose method was to set forth the arguments against his thesis, then the arguments for the thesis, and finally to answer the objections. Saint Thomas practically adopted the method as he found it in use in the schools of his day, giving to each article discussed the recognized tripartite division *videtur quod non* (introducing objections), *sed contra* (introducing the argument for his thesis), and *respondetur ad primum,* etc. (answers to objections). Underlying this somewhat formal method was the principle which the schoolmen derived from Aristotle, that it is only by the dialectic discussion of the affirmative and negative sides of a question the truth is to be discovered and defined. In other words, the faculty of the mind on which philosophy chiefly relies is not intuition but ratiocination.

In describing the content of Saint Thomas' philosophy one must advert, in the first place,

to the Aristotelian mold in which all his philosophical doctrines are cast. For him Aristotle is the philosopher. On the questions of method and doctrine which divide the Platonists from the Aristotelians Saint Thomas unhesitatingly and invariably takes the side of Aristotle. In fact, he is the Christian Aristotelian in the sense in which Saint Augustine is the Christian Platonist. It would, however, be fatal to a proper estimation of his philosophy to overlook the elements in it which cannot be traced to Aristotle. He was no slavish imitator; he maintained as a principle of method that the argument from authority is (in philosophy) the weakest of all arguments. It was only in the age of decay of the philosophy of the schools, when the letter rather than the spirit ruled the tradition of Thomistic teaching, his name and the name of Aristotle were invoked as authority to put an end to all discussion.

To say that Saint Thomas was an Aristotelian means little when we remember that in his day there were mere followers of Averroes, materialists and pantheists, who might with equal justice claim to be representatives of the Stagyrite. Saint Thomas was an Aristotelian who brought to the elucidation of his Master all the tradition of Christian speculation from Justin, the first of the Apologists, down to his own immediate predecessors and contemporaries. The thought which inspired the Christian philosophers was that above the order of natural truth, that is, of truth which can be attained and comprehended by the human mind unaided, there is another order of truth, the supernatural, which human reason cannot of itself attain, but which is known to us on the authority of divine revelation. Natural truth belongs to reason, and supernatural truth to faith. Christian philosophy from the beginning took its stand on the principle that these two orders of truth must, in some way, be capable of harmonious adjustment. Rationalism exaggerated the power of reason, mysticism tended to slight reason and to emphasize and unduly extend the scope of faith. Throughout the early Middle Ages these two tendencies were at war with each other in the Christian schools. It is one of Saint Thomas' chief titles to distinction that he united in his system what is true in rationalism with what is true in mysticism. The rationalism of Abelard obliterated all distinction between supernatural and natural truths, when it treated mysteries of faith as if they were conclusions of theology and used the Scriptures as if they were sources of argument in philosophy. In an opposite sense, the mysticism of Erigena removed all distinction between the two orders of truth, when it maintained that even truths of the natural order are known to us by a special *theophania*, or divine manifestation. Saint Thomas taught that the two orders of truth are distinct: that our knowledge of supernatural truth rests on the authority of revelation, while our knowledge of natural truth rests on the evidence of reason. He maintained, at the same time, that they are consonant with each other, that since God is the author of all truth there can be no contradiction between what revelation proposes for our belief and what reason proclaims to be evident. This thought, namely, that revelation is reasonable and reason divine, crystallized the fundamental concepts of all the preceding systems of Christian speculation, reconciled mysticism with rationalism and gave permanent form to the *credo ut intelligam* and the *intelligo ut credam* of scholasticism. The reconciliation of reason with revelation is of interest not merely to the Christian Apologist but to the philosopher as well. For it is inspired by the desire to establish between the supernatural and the natural that relation of continuity which Greek philosophy at the highest point of its development established between the spiritual and the material.

To the controversy concerning the mode or manner of the existence of universals, which, during the 11th and 12th centuries, had been so prominently before the minds of philosophic thinkers, Saint Thomas contributed his doctrine of moderate Realism. The Nominalists contended that universals are mere names; the exaggerated Realists, influenced for the most part by Plato, maintained that universals are things really existing outside the mind as completely developed universal forms. The doctrine of moderate Realism (q.v.) is that, while universals are not mere names but real things, they exist outside the mind not as full-blown universals but only as potentially universal essences which receive their formal aspect of universality from the mind in the act by which it compares and discusses individual objects and abstracts therefrom the formally universal concept. Saint Thomas found this doctrine established in the schools of his time. He adopted it and gave to it, as to so many other tenets of the schools, its final and most clear-cut form.

One of Saint Thomas' most noteworthy contributions to philosophy was his elucidation in the Christian and theistic sense of some of the more obscure points of Aristotelian teaching. Having before him a translation made directly from the Greek text — a translation which is, indeed, far from correct, yet which in spite of many ludicrous verbal blunders is immeasurably superior to the translations made through the medium of Syriac and Arabic — he sought to free from the accretion of Neo-Platonic and Arabian commentary the original doctrine of Aristotle on the question of the nature of the Active Intellect. Rejecting what may be called the transcendentalist view, which held the Active Intellect to be something more than human, something akin to God and in some way common to all men, he defended the anthropological view, which held that the Active Intellect is a part of the individual soul, and, therefore, not common to all, but proper to each. In this way, he strengthened the defense of the immortality of the individual soul.

Saint Thomas founded a school within the schools. To the Franciscan teachers, such as Alexander of Hales, Saint Bonaventure, and Roger Bacon, certain doctrines of Saint Augustine recommended themselves, to the detriment of the strict Aristotelianism which they professed. These Franciscan teachers were opposed by the Dominicans, who, like Albert the Great and Saint Thomas, recognized in the Augustinian doctrines in question an element of Platonism which was inconsistent with thorough Aristotelianism. The struggle between Augustinianism (q.v.) and Aristotelianism (q.v.) was waged in the schools, especially at Paris, during the first decades of the 13th century. The doctrines under discussion were

mostly psychological: for instance, the Aristotelians maintained that there is but one substantial form in man, the soul, while the Augustinians maintained that there are several substantial forms; the latter contended that there is no real distinction between the soul and its faculties, while the former defended the real distinction; the Aristotelians maintained that there are subsistent forms, that is to say, purely spiritual created substances, without any matter, while the Augustinians taught that all creatures, even the angels, are composed of matter and form. On all these questions Saint Thomas took the part of the Aristotelians and thus became the leader in the Dominican, or, as it is sometimes called, the Thomistic school in the stricter sense of the word.

The controversies between the Dominican and the Franciscan schools brought out an important general trait of Saint Thomas' philosophy. Duns Scotus (1274–1308), the ablest of the Franciscan opponents of Saint Thomas, adopting the principle of voluntarism, brought to the surface the intellectualism which pervades Saint Thomas' speculative system. Saint Thomas pushed to its utmost consequences the *intelligo ut credam* of the earlier scholastics: he made intellect superior to will and sought in every thing to find an intellectual basis for belief. Scotus maintained that on many questions of the highest importance reason fails to give a satisfactory explanation or proof and that we must fall back on will.

To say, however, that Saint Thomas was an Aristotelian in the Christian, as opposed to the Averroistic, sense; that he gave final form to the idea which inspired scholastic, and indeed all Christian, speculation; that he was a moderate Realist; that he held to the strict systematic Aristotelianism and excluded certain Augustinian and Platonic elements; that he was an intellectualist, is to give but a faint idea of his claims to pre-eminence as a representative of scholastic philosophy. Of him, as of all the great speculative thinkers, it may be said that the spirit of his work is more potent than the letter. To the modern mind, especially, he appeals in virtue of the spirit in which he undertook the work of adjusting his beliefs as a Christian to the scientific and philosophic thought of his age. To this task he addressed himself with an instinctive sense of completeness which impelled him to leave nothing incomplete or imperfect except so far as everything human is incomplete and imperfect. He brought to his task a mind appreciative of the value of truth wheresoever truth is found, whether in pagan, Jew, or gentile, and a belief — stronger in him than in any other Christian writer since Saint Augustine — that all truths and all contributions to knowledge, from whatsoever source they are derived, must be capable of harmonious adjustment.

Arabesque, ăr'a-bĕsk', a term applied to a particular species of decoration employed in Arabian and Moorish architecture. The followers of Mohammed, being prohibited by the Koran from representing the figures of men and beasts, endeavored to evade this law by inventing a series of monsters, griffins, dragons, strange birds, and chimeras; affixing the head, wings, and talons of birds to the bodies of lions, horses, and other quadrupeds; and making the upper parts of children, men, and beasts spring from among clusters of foliage and the like. In the Vatican there are paintings, executed by Giovanni da Udine from the drawings of Raphael, in this style, which are deservedly much admired.

Arabgir, ä'rab-gēr', or **Arabkir**, a town in Asiatic Turkey, 147 miles southwest of Erzeroom. It owes its enlargement and prosperity to the Armenians, who form about one fourth of the population, and it is especially noted for its manufacture of silk and cotton goods. Pop. about 28,000.

Arabi, a-rä'be, **Ahmed El** (usually known as "Bey" or "Pasha"), an Egyptian national leader: b. in Lower Egypt about 1837. He was the son of a common peasant, and, entering the army, rose to the rank of colonel and became the head of a party desiring to restore native control of Egypt. Tewfik, the khedive, too sluggish and timid to join the party openly, was nevertheless glad to see the movement prosper under the leadership of one with more energy than himself. The ministry of the ablest of Egyptian statesmen, Nubar Pasha, was presently overthrown, and Arabi made minister of war in the new cabinet. Flushed with success, the new war minister acted as if head of the state, and rashly undertook to overthrow the Anglo-French control of the finances. The bombardment of Alexandria, 11–12 July 1882, by order of the Gladstone ministry, and the rout of his army at Tel-el-Kebir, 13 Sept. following, ended his dream, and he was sent into life exile in Ceylon. He was pardoned and returned to Egypt in 1901.

Ara'bia, the peninsula in the southwestern part of Asia, called by the natives Jeziret el Arab, that is, the Peninsula of the Arabs; and by the Turks and Persians, Arabistan. It is encompassed on three sides by the sea, namely, on the northeast by the Persian Gulf, on the southeast by the Indian Ocean, and on the southwest by the Red Sea. Its extreme southern point, Ras-Arah (the Cape St. Anthony of some maps), lies in lat. 12° 35' N.; lon. 44° 4' E. Thirty miles west of it are the Straits of Bab-el-Mandeb. The extreme eastern point of Arabia, Ras-el-Had, stands in lat. 22° 23' N.; lon. 60° 5' E. A line drawn from the head of the Gulf of Suez to that of the Persian Gulf, and marking the limits of the Arabian peninsula on the north, will be found to run nearly in the 30th parallel of north latitude, but a portion of what is considered Arabia extends north of this. Arabia includes also the peninsula of

Sinai, between the Gulf of Suez and that of Akabah. The whole area of the vast country thus described does not probably fall much short of 1,000,000 square miles.

Divisions.— According to Ptolemy, ancient Arabia consisted of Arabia Petræa, Arabia Deserta, and Arabia Felix, a division likewise followed in modern times, but which is not only founded on erroneous principles, but unwarranted by the example of the inhabitants of the country. The name of Arabia Felix, or Arabia the Happy, is derived from an incorrect translation of the word *Yemen,* which does not signify happy, but the country lying to the right of Mecca, in the same manner as the Arabic term for Syria, Al-Sham, denotes the country lying to the left of that city. Arabia Petræa likewise has been erroneously translated Stony Arabia, the epithet Petræa having been bestowed on it by Ptolemy, from the once flourishing city of Petra.

The first of the divisions met with in proceeding down the Red Sea is Hejaz, which, as it includes the sacred cities Mecca and Medina, is always set forth conspicuously by Arab geographers. It extends a short way within the mountain barrier and terminates in the south in about lat. 20° N. Next comes Yemen, which, according to some writers, embraces the whole of south Arabia; but the name is now generally used in a confined sense, Yemen proper occupying the southwest part of the peninsula, and comprising a Tehama or maritime lowland on the shores of the Red Sea, with an elevated inland district of considerable breadth. It contains the towns of Sana and Mocha. Appertaining to Yemen is Aden, now a free port in the hands of the British. Next Yemen, on the east, is Hadramaut, the western portion of which is a desert five days' journey in length. The limits of this province are, however, variously assigned by authors, some extending the name to almost the whole of the southeast coast, while others confine it to a district only 100 miles in length. Beyond Hadramaut, in the latter narrower sense, lies Mahrah, beyond which again extends the principality of Shejer or Shehr, at the eastern termination of which, near the coast, is the populous district of Dhofar, which has occasionally figured as an independent State. At the east angle of the peninsula is situated Oman. On the south shores of the Persian Gulf is Bahrein, from which, toward the head of the Gulf, extends the maritime district of Hajar, while at a short distance southwest in the interior lies the fertile district of El-Ahsa, the name of which is sometimes also given to the coast. The interior of Arabia from Hejaz and Yemen across to the vicinity of the Persian Gulf is comprised by Arab geographers under the single name of Nejed. Toward the north are the deserts of Sinai, and those of Sham, Jezíreh, and Irak (Syria, Mesopotamia, and Babylon). The two most populous districts are Yemen and Oman. See Palgrave, 'Central and Eastern Arabia' (1862–3).

The climate of Arabia resembles that of Africa. The mountains obstruct the mitigating influence of the sea breeze; scorching aridity and barrenness characterize both high and low grounds, and the date palm is often the only representative of vegetable existence. There are even districts which in the course of the year are refreshed by only one shower of rain, while a sky almost perpetually unclouded overspreads the sterile plains. The short rainy season, which, in consequence of the shifting winds prevailing in the Red Sea, visits the west coasts in our summer months, fills with water, but only periodically, the depressions in the surface, or *wadis,* and a winter marked by slight frosts occurs in the table-lands of the interior and northeast. The simoom occasionally blows during the hot season, though only in the northern districts.

Productions.— Arabia is destitute of large forests, and plains of green turf have their place supplied by steppe-like tracts, which, however, covered with aromatic herbs, afford excellent pasture to noble breeds of horses. The terrace portions of the country, which enjoy a more temperate climate, exhibit a greater luxuriance of vegetation. Here the date and cocoanut palms and various excellent sorts of fruit flourish along with durra (a species of millet which is here generally cultivated instead of European corn), the finest coffee in the world (the staple commercial product of the country), and many aromatic plants and substances, such as gum-arabic, benzoin, mastic, balsam, aloes, myrrh, frankincense, etc. There are also cultivated in different parts of the peninsula, according to the nature of the soil and climate, beans, rice, lentils, tobacco, melons, saffron, colocynths, poppies, olives, the kath bush (*Catha* or *Celastrus edulis*), the leaves of which are in general use, like those of the coca in Peru, as an excitant, sesame, the castor-oil plant, etc. In its fauna also, as corresponding with the desert nature of the country, Arabia presents much of an African type. Sheep, goats, and oxen supply man's immediate domestic and personal wants; the horse and camel are his faithful attendants on his wide peregrinations; asses and mules, of a stronger make and better appearance than those of Europe, are common in the mountainous districts; the desert is inhabited by gazelles and ostriches hurrying rapidly from oasis to oasis; and the lion, panther, hyena, and jackal crouch in ambush for the passing prey. Monkeys, pheasants, and doves are the peaceful occupants of the fertile districts, in which, however, locusts frequently commit tremendous havoc. There are several species of serpents and lizards, and scorpions and poisonous spiders are numerous. Fish and turtles abound on the coasts, and pearl oysters in the Persian Gulf. Among mineral products may be mentioned saltpetre, mineral pitch, and petroleum, which are found in the interior highlands, salt, sulphur (in Hadramaut), and several precious stones, as the carnelian, agate, and onyx. Iron, copper, and lead are far from abundant, and the country is also poor in the precious metals.

Population.— The population of Arabia has been estimated by some authorities at 12,000,000, by others at no more than 4,000,000. The former number is certainly too high, and it is believed that between 5,000,000 and 6,000,000 is nearer the truth. The Arabs present, as a nation and as individuals, much that is peculiar both in their mental and physical development. They are of middle stature, of a powerful make, and have skin of a brownish color. Their fea-

tures express dignity and pride; they are naturally active, intelligent, and courteous; and their character is marked by temperance, bravery and hospitality, along with a strong propensity for poetry. On the other hand, they are revengeful in their disposition and predatory in their habits. The women have the entire education of the children in their early years. The most fortunate events in the estimation of an Arab are the birth of a camel, a mare of noble breed bringing forth a foal, or a triumph achieved by a poet. The first religion of the Arabs, the worship of the stars, was supplanted by the doctrines of Mohammedanism, which succeeded rapidly in establishing itself throughout Arabia. Besides the two principal sects of Islam, the Sunnites (the most numerous) and the Shiites (on the east coast), there also exists, in very considerable numbers, a third sect, the Wahabees, which arose in the latter half of the 18th century, and to which the Bedouins of Nejed belong. There are also numerous Jews, who dwell among the Arabians and are chiefly employed in trade.

The whole of the west coast, comprising the districts of Hejaz and Yemen, and in quite recent times part of the east coast, namely, the republic of Koweit at the head of the Persian Gulf, and the district of El Ahsa, are more or less under the suzerainty of the Turks. The area of the western strip is about 200,000 square miles in extent, and has a population of about 1,130,000; while the eastern has an area of about 31,000 square miles and a population of nearly 200,000. Even in these districts, however, the chief offices of government are performed by the chieftains of the small territories into which the districts are subdivided. The most extensive districts politically united in the rest of Arabia are the kingdoms of Oman and Nejed, the former with an area of 81,000 square miles and a population of 1,598,000; the latter (the kingdom of the Wahabees) with an area of perhaps 200,000 square miles and a population of about 1,219,000.

The mode of life of the Arabs is either nomadic or settled, or in other words, they either live in tents and derive their subsistence from the rearing of cattle, wherever sufficient pasture is obtainable, and from the transport of caravans through the desert; or from the pursuits of agriculture and commerce. The nomadic tribes in Arabia are termed Bedouins, Beduins, or Bedawins; those following settled occupations, Hadji and Fellahs. A considerable trade, partly overland, partly maritime, is carried on, chiefly in coffee, dates, figs, spices, and aromatic substances of various kinds, though its present amount is scarcely a shadow of what it was in times previous to the discovery of the passage by the Cape of Good Hope. Commerce is partly in the hands of foreigners, among whom the Jews and Banians are the most numerous. The latter are a tribe of Indian merchants, who, however, only remain long enough in the country to enable them to return with wealth to their own land. At present the trade of Arabia is almost exclusively confined to exports of raw material or imports of foreign manufactures, domestic industry being scarcely able to supply the most necessary articles of consumption, and the inhabitants are thus rendered dependent on foreign nations for the greater portion of their manufactured commodities. The period of intellectual development among the Arabs is now indeed long past its zenith, but it does not appear yet to have sunk so low as is often assumed. Even in the desert children are taught to read, write, and cipher, and in the towns there are higher schools for satisfying the taste for scientific pursuits. The political constitution of the Arabs is patriarchal, and based on a love of freedom. The titles of the chiefs of the tribes are emir, sheikh, or imam, personages whose functions appear in general to be limited to the command of the army in war, the collection of tribute, and the administration of law by the cadis or judges.

History.— The history of the Arabs previous to Mohammed is obscure, and, owing to their slight connection with the rest of the world, of little interest. The evidence of language, tradition, and other things, establishes the fact that Arabia must have been settled at a very early date by two branches of one race. One of these branches inhabits the south and east of the peninsula (Yemen, Hadramaut, and Oman), and considers itself as forming the "pure" Arabs, while to the other branch it gives the name of Mostareb, or "Arabified." The oldest traditions regarding the origin of the former branch point to an immigration from Africa which took place about the southwest corner of the peninsula, and the physical appearance and structure of the southern Arabs, the remnants of their dialect (which is now superseded by that of the northern branch), and various institutions and customs prevailing in the parts of Arabia inhabited by them, all confirm the notion that they were originally identical with the nearest inhabitants of Africa. The northern branch, on the other hand, though bearing an unmistakable affinity with the southern, shows (in its language and other respects) more traces of Asiatic than African influence. The Arabs of the southern branch were the first to attain any considerable political power. A kingdom belonging to this branch is said to have existed in the south for upward of 2,000 years, embracing, when in a flourishing condition, the whole of the south half of the peninsula, and sometimes extending its boundaries by conquest very much farther. There is no doubt that there was actually such a kingdom, called the kingdom of Yemen, and having its capital first at Mareb and afterward at Sana, both in the district of that name; but how long that kingdom subsisted cannot be determined. Its kings belonged to the Himyarite dynasty, but this designation Himyarite is sometimes applied by Arab writers to the ruling classes of the southern branch, and sometimes to the whole branch. The Yemenite kingdom was rendered subject by the Abyssinians for upward of 70 years in the 6th century of the Christian era, during which period Christianity was proclaimed in the land. Ultimately the heir to the throne of the Himyarite dynasty was restored through the assistance of Chosroes, king of Persia (605 A.D.), but about 30 years later the kingdom was finally overthrown by the followers of Mohammed. Another Himyarite kingdom was that of Hira on the west shore of the lower Euphrates. It seems also to have extended at times to the region between the

Euphrates and the Tigris, so as to give the name of Irak Arabi to that district. The dates given for the foundation of this kingdom are widely different. Its overthrow is placed in the 5th century of our era. In the 1st century of the Christian era the Himyarite kingdom of Ghassan was founded in lower Syria and Hejaz. It lasted till the time of Mohammed. The last Himyarite kingdom that need be mentioned is that of Kindeh, which detached itself from that of Hira early in the 3d century, and lasted about 160 years. Its sway extended over northern Nejed. The divided forces of the Arabs could not always successfully resist the Roman arms, and though their country was never completely reduced to the condition of a province, yet the princes in the north at least lived in a state of dependence on the Roman emperors, and were regarded as their viceroys. In the south the Romans had no influence. An expedition was fitted out against Yemen in the reign of Augustus (24 B.C.), but it completely miscarried. With the decline of the Roman empire Arabia made vigorous struggles for independence, which could easily have been brought about by a union of the various tribes. But the Arabian peoples continued dispersed and broken, and passed many centuries in internal conflicts, during which the central highlands (Nejed) became the theatre of those chivalrous contests so celebrated by the native poets. Christianity early gained many adherents in Arabia, though it did not succeed in entirely banishing the ancient worship of the stars. Several Christian bishoprics were established, subject to the metropolitan at Bozra, in Palestine. The town of Elhira, near the Euphrates, contained many Arabian Christians and convents, and the reigning king, Ennomân-ben-el-mondsir, became a convert to Christianity not long before the time of Mohammed. The conflict of the Arabs with Roman despotism was more especially the cause of attracting to their country numbers of Christian sects, among others the Monophysites and Nestorians, seeking a refuge from the persecutions to which they were subjected by the maintainers of orthodoxy throughout the East. Jews also were very numerous in Arabia after the destruction of Jerusalem, and even made some proselytes, chiefly in Yemen. The wide differences between the various sects produced in the minds of many an indifference to all the existing religions, and was probably one of the principal causes that the doctrines of Mohammed found so speedy an acceptance in Arabia. With Mohammed a new phase commences in the history of the Arabian peoples, who are wont to designate respectively the periods before and after the appearance of the Prophet as those of ignorance and knowledge. Mohammed belonged to the Mostareb, and among them to the tribe of Koreysh, which had occupied a position of great influence in Arabia since the beginning of the 5th century, when it managed by craft to obtain possession of the city of Mecca, which was not only a city of great commercial importance, but was regarded as sacred by the Arabs on account of its containing the Kaaba. During the whole of the 6th century the Mostareb generally were increasing in power, and by the beginning of the 7th, when Mohammed had grown to manhood, they had absorbed the kingdom of Kindeh, and had extended their sway at the expense of those of Yemen, Hira, and Ghassan. By the time of Mohammed's death, in 632, his religion had acquired a firm hold in Arabia, and after that event his successors, acting on the commands of the Koran, began to spread it by force of arms beyond the bounds of the peninsula. The nation, now for the first time acting as a body, played for several centuries an important part in the world's history, advancing in a career of victory beyond its natural frontiers, to found empires in three quarters of the globe. The brilliant period of Arabian history, indeed, as regards foreign countries, came to a termination in Asia in 1258, on the fall of the caliphate of Bagdad, as also about the same time in Africa and Europe, in the latter of which the Moorish dominion was finally overthrown (in the kingdom of Granada in Spain) in the last decade of the 15th century; yet the epoch of the Arab sway must ever occupy a distinguished place in the intellectual history of mankind. The internal history of the country during its foreign conflicts presents little more than unimportant accounts of some Bedouin tribes, and the fortunes of the caravans which made the annual pilgrimage to Mecca. In 1517 Turkey subjected Hejaz and Yemen, and received the nominal submission of the tribes inhabiting the rest of Arabia. The subjection of Hejaz has continued down to the present day, with a brief interval in the latter half of the 16th century, and another longer interval in the 19th century, when the pasha of Egypt was dominant in Arabia; but Yemen achieved its independence in 1630 and maintained it till 1871, when the territory again fell into the hands of the Turks. In 1839 Aden, in Yemen, was occupied by the British.

In the east Oman became virtually independent of the caliphs in the middle of the 8th century, and grew into a well-organized kingdom. In 1507, however, its capital, Maskat or Muscat, was occupied by the Portuguese, who were not driven out till 1651. Oman was temporarily subjugated by the Persians under Nadir Shah in the first half of the 18th century. They were expelled by Saood, who was made imam of Oman, and under whom it extended its sway over part of the opposite coast of Persia as well as the islands lying between and over the coast of Zanzibar. Since 1867 the kingdom of Oman has been again confined to the mainland of Arabia. The appearance of the Wahabees about the middle of the 18th century is the first event since the time of Mohammed that affected Arabia generally. The moral effects of this event exercise still a powerful influence; the political were soon effaced by the ruler of the neighboring country of Egypt. Mehemet Ali, pasha of Egypt, subdued the coast of Hejaz, as also several places on that of Yemen, and in 1818, by means of a great victory gained by Ibrahim Pasha, and the destruction of their capital city Derreyeh, put a stop to the further extension of the Wahabite power. He also expended large sums in the maintenance of his sway in Arabia, which secured to him the trade of the Red Sea. The events of 1840, however, in Syria, compelled him to concentrate his forces, and he soon found himself obliged, as thwarting the Euro-

pean line of policy, to renounce all claims to the territories lying beyond a line drawn from the Dead Sea to the Gulf of Akabah. The Hejaz thus again became immediately subject to Turkish sway. Turkey has since extended its rule not only over Yemen as already mentioned, but also over the district of El Ahsa on the Persian Gulf; but the extreme weakness of the Turkish empire scarcely warrants the expectation that its tenure of power in Arabia will last very many years longer.

Language.— The Arabic language belongs to the Semitic dialects, among which it is distinguished for its richness, softness, and high degree of development. By the spread of Islam it became the sole written language and the prevailing speech in all southwestern Asia and eastern and northern Africa, and for a time in southern Spain, in Malta, and in Sicily; and it is still used as a learned and sacred language wherever Islam is spread among people who in daily life speak Indian, Persian, or other languages. The study of Arabic is important not only on account of the wide area over which it is still spoken and the extensive literature it contains, but also because it is almost an indispensable preliminary to the study of some of the other languages of the East. Almost a third part of the Persian vocabulary consists of Arabic words, and there is the same proportion of Arabic in Turkish. A scientific treatment of the Hebrew language first became possible through comparing it with the Arabic. The characters originally used in writing the Arabic language were borrowed from the old Syrian Estrangelo alphabet, which, however, was very inadequate for the purpose, having only 16 signs for the 28 Arabic consonants. This alphabet is now superseded by the Neski. As in all Semitic languages (except the Ethiopic) it is read from right to left. There are valuable Arabic grammars by Erpen (1613), De Sacy (1831), Ewald, Caspari, Wolff (2d ed. 1867); and in English by Wright (based on that of Caspari, but practically a new work, 1874–5), and Palmer (1874). The great standard Arabic-English dictionary is that of E. W. Lane (continued by his nephew, Lane Poole, a most extensive work). Other valuable works are Richardson's 'Persian-Arabic-English Dictionary'; Newman's 'Dictionary of Modern Arabic' (1871); Badger's 'English-Arabic Dictionary' (1881); and Salmoné's 'Arabic-English Dictionary' (1890).

Literature.— Of the first cultivation of the literature of this country we have but few accounts. That poetry early flourished in Arabia may be inferred from the character of the inhabitants, who are at the present day much given to poetry. In the fairs of Mecca and (from the 5th century after Christ) at Okadh, poetical contests were held, and the poems to which the prize was awarded were written on byssus in letters of gold, whence they were called *Modsahhabat* (gilt), and hung up on the wall of the sacred temple containing the kaaba at Mecca, on which account they also got the name of *Moallakat* (hung up). The collection of the Moallakat contains seven poems by seven authors — Amr-ul-kais, Tarafa, Zohair, Lebid, Antar, Amr-ben-Kelthum, and Hareth. They are distinguished by deep feeling, lofty imagination, richness of imagery and sentiment, national pride, and love of freedom. Many other poems belonging to the time before Mohammed, some of equal age with those of the Moallakat, are also preserved in collections. The influence of Mohammed gave a new direction to Arab poetry. The rules of faith and life established by him were collected by Abubekr, first caliph after his death, corrected and published by Othman, the third caliph, and constitute the Koran. The warlike times of Mohammed and the first caliphs, however, were not favorable to the cultivation of literature. The progress of the Arabs in the arts and sciences may be said to have begun with the government of the caliphs of the family of the Abassides, A.D. 750, at Bagdad. Here Haroun al Rashid (786–808) invited learned men from all countries and paid them princely salaries. He caused the works of the most famous Greek writers to be translated into Arabic and spread abroad by numerous copies. Under the government of Al Mamum (813–33) excellent schools were established at Bagdad, Bassora, Bokhara, Cufa, and large libraries at Alexandria, Bagdad, and Cairo. The caliph Motassem, who died A.D. 842, was of the same disposition, and while literature was thus favored by the dynasty of the Abassides in Bagdad, it received not less encouragement from that of the Ommiades in Spain. What Bagdad was for Asia, the university at Cordova was for Europe, where, particularly in the 10th century, the Arabians were the chief pillars of literature. At a time when learning found scarcely anywhere else a place of rest and encouragement, the Arabians employed themselves in collecting and diffusing it in the three great divisions of the world. In Spain were established numerous academies and schools, which were visited by students from other European countries; public libraries were collected, one of them said to contain 600,000 volumes; and important works were written on geography, history, philosophy, medicine, physics, mathematics, and especially on arithmetic, geometry, and astronomy. There are a number of terms still in use, such as almanac, algebra, alcohol, azimuth, zenith, nadir, which were borrowed originally from the Arabs. The most of the geography in the Middle Ages is the work of the Arabians. Among their chief writers on geographical subjects are El-Istakhri, 'Liber Climatum', edited by Möller (1839); Abu-Ishak-al-Faresi, Ibn-Haukal, who wrote about 815, 'El-Edrisi,' 1150 (French translation published by Jaubert 1836); Yakuti, who died in 1249, and Abulfeda; and much that the most renowned among them, Abulfeda and Edrisi, have written, is still useful and important in regard to historical geography. Even more important than the geographical text-books are the descriptions of countries which were written by Arab travelers; such as those by Ibn-Foslan, who traveled in Russia in the 9th century; by Mohammed ibn-Batuta, who traveled in Africa, India, China, Russia, etc., in the 13th century; and by Leo Africanus, who traveled in Africa and Asia in the 15th century.

The Arabian historians since the 8th century have been very numerous, though not yet long enough known to European scholars to enable the latter to derive full advantage from them. The oldest known historian is Hesham

Ben-Mohammed Al-Kelbi (died 819). Several other historians lived in the same century. Masudi, the Persians Tabari and Hamsa of Ispahan, and the Christian patriarch Ibn el Batrik or Eutychius of Alexandria, were the first that attempted universal histories. These were followed by Abulfaraj and George Elmakin, both Christians, Abulfeda, Nuvairi, Alfachri, and others. Native historians wrote on the history of the Arabs in Spain and in Mauretania; others, such as Abdullatif and Makrisi, wrote on the history of Egypt; others compiled biographical dictionaries or wrote lives of individuals. The style of most of the historians is simple and void of ornament. Indeed their histories are little more than voluminous chronicles. The philosophy of the Arabians was of Greek origin and derived principally from that of Aristotle, who through them became known in Spain and thence in all the west of Europe, having been translated from Arabic into Latin. Hence the origin of the scholastic philosophy may be traced to the Arabians. The Arabians seem to have become acquainted with the works of the Greek philosophers in Bagdad, where a knowledge of them was disseminated by the Nestorian Christians who had been expelled from Syria in the 5th century and found refuge and patronage in Persia. During the 8th and 9th centuries numerous versions of the principal works of Aristotle were made into Syriac and thence into Arabic; and once Aristotle had been introduced to their knowledge the Arabian philosophers both in the east and the west did little else than advance nearer and nearer to a faithful interpretation of that master. Of their philosophical authors the most celebrated are Alfarabi (died 950), who wrote on the principles of nature; Ibn Sina, or Avicenna, who was born about 980 and died A.D. 1037, and, besides other philosophical writings, was the author of a treatise on logic, physics, and metaphysics, and of a commentary on the works of Aristotle; Alghazzali (1058–1111), who wrote a work attacking all heathen philosophical systems; and in Spain Avicebron (died 1070), a Jew, the same with Solomon ben Gebirol; Ibn Badja, known to Europeans as Avempace (died 1138); Ibn Tofail (died 1190); and (one of the greatest of them all) Ibn Roshd, or Averroes (1126–98). Of these, Avicenna was by far the most important, and his influence on Western thought was considerable.

Nearly all the Arabian philosophers were at the same time physicians; for the physical sciences, including medicine, were not then separated from philosophy. At Jondisabur, Bagdad, Ispahan, Firuzabad, Bokhara, Cufa, Bassora, Alexandria, and Cordova, from the 8th to the 11th century medical schools were instituted, and with the devoted study bestowed on this branch of science the nation could not fail of making important advances in it, though in reality they were here also dependent on the Greeks. Anatomy made no progress among them, because the Koran expressly prohibited dissections. To their famous writers on medicine belong Aharun (who first described the smallpox), Jahiah Ben Serapion, Jacob Ben Ishak Alkendi, John Mesve, Rhazes, Ali Ben Abbas, Avicenna (who published the 'Canon of Medicine,' for a long time the best work of the kind), Ishak Ben Soleiman, Abulcasim, Ibn

Zohar, Averroes (the author of 'A Compendium of Physic'). Mathematics the Arabians enriched, simplified, and extended. Mohammed Ben Musa and Thabet Ben Korrah particularly distinguished themselves in this department. Nassireddin translated the 'Elements' of Euclid. Jeber Ben Afla wrote a commentary on the 'Trigonometry' of Ptolemy. Astronomy was especially cultivated, there being famous schools and observatories at Bagdad and Cordova. As early as A.D. 812 Alhazen and Sergius had translated into Arabic the 'Almagest' of Ptolemy, the first regular treatise on astronomy. Albatani, in the 10th century, noted the advance of the line of the earth's apsides and the obliquity of the ecliptic. Alpetragius wrote a theory of the planets. Geography was treated scientifically, in connection with mathematics and astronomy, particularly by Abulfeda. The Arabian scholars devoted much time to grammar and rhetoric, particular attention being paid to expounding the Koran and in preparing works dealing with it.

Much as the severer sciences were cultivated the genius of the people for poetry was not fettered. After the 9th century the Oriental peculiarities of Arabian poetry became more and more strong; the tone grew mystical and extravagant and the language lost its purity. Motenabbi deserves to be noticed for his tender elegies in a classic style; Abu Ismael Tograi, vizier of Bagdad, for his elegies and poems; Hariri for his history of an unscrupulous but amusing vagabond in his work entitled 'Mekammat,' admirably translated into German by Rückert, into English by Chapellon and Preston; Ibn-Arabshah for his narrative tales, etc.; Asmai for his great heroic romance, 'Life of Antar.' The dramatic excepted, there is no sort of poetry which the Arabians have left unattempted. There is no doubt that they had by this means a powerful effect on modern European poetry, for no small share of the romantic poetry of the Middle Ages belonged to the Arabians. The tales of fairies, genii, enchanters, and sorcerers in particular passed from the Arabians to the Western poetry. Some of the books most widely read in the Middle Ages, such as 'The Seven Wise Masters' and the 'Fables of Pilpay,' found their way into Europe through the instrumentality of the Arabs. To this rich and many-sided intellectual life among the Arabs in the Middle Ages the intellectual poverty of the 19th and past two or three centuries offers a striking contrast. Arab literature now scarcely offers anything worthy of notice. Learning is chiefly confined to the production of commentaries and scholia, discussions on points of dogma and jurisprudence, and grammatical works on the classical language. Among authors who have written to a certain extent under the influence of European culture we must mention Michael Sabbagh of Syria ('The Carrier Pigeon,' Arabic and French, Paris 1805); Sheikh Refaa of Cairo ('The Broken Lyre,' Paris 1827; 'Manners and Customs of the Europeans,' Cairo 1834); Nasif-Effendi of Beyrout, and Ahmed Faris (died 1887), journalist and miscellaneous writer. Translations of modern European works (Jules Verne's and others) are numerous. A number of periodicals are published in Arabic.

Ara'bian Nights Entertainment, The, a celebrated collection of Arabic tales, first introduced into Europe in the beginning of the 18th century by means of the translation of Antoine Galland, a distinguished French Orientalist, which was hailed with universal delight, and soon became one of the most popular works in Europe. The story which connects the tales of the 'Thousand and One Nights' is as follows: The Sultan Shahriyar, exasperated by the faithlessness of his bride, made a law that every one of his future wives should be put to death the morning after marriage. At length one of them, Shahrazad, the generous daughter of the grand vizier, succeeded in abolishing the cruel custom. By the charm of her stories the fair narrator induced the Sultan to defer her execution every day till the dawn of another by breaking off in the middle of an interesting tale which she had begun to relate. The delight felt by Shahriyar has been felt by multitudes since his time, and the universal popularity of the 'Arabian Nights' is unequivocally evinced by the numerous translations in different European languages which have appeared since the time of Galland. Lane, who resided for years at Cairo and published an excellent (abridged) translation of these tales, with numerous most valuable notes (1839), considered that they took their present form some time between 1475 and 1525. A complete (unexpurgated) translation of great value by Sir R. F. Burton has been published (1885–6), with a somewhat abridged edition by Lady Burton (1887–8). There is also a modern translation by Mr. Payne (1882–4).

Ara'ceæ, the designation of an order of endogenous plants having for their inflorescence a spadix placed within a spathe. They have neither calyx nor corolla. The leaves are frequently cordate; the fruit succulent, with many seeds. They are acrid in character and often poisonous. The *Caladium sequinum*, or dumb cane of the West Indies and South America, when chewed, causes the tongue to swell so as to cause temporary dumbness. A common English species is the wake-robin. The nearest relatives of the family in America are the Indian turnip, water-arum, and skunk's cabbage.

Arach'nida, the name applied to the class of arthropods represented by the scorpion, spider, and mite. The body is divided into two regions, the cephalothorax and abdomen, the head having been in embryonic life folded back over and fused with the thorax. There are no antennæ, the first pair of appendages resembling mandibles, and called cheliceræ; the second pair end in a large forceps, or chelæ, or in a palpus-shaped appendage called "pedipalpi." The head appendages are not differentiated into antennæ, mandibles, maxillæ, and maxillipeds, as in *Crustacea*. There are four pairs of legs ending in a pair of minute claws. On the abdomen there are no appendages. The respiratory organs are spiracles opening into tracheas or air-tubes, or pouches containing numerous leaves or their sacs, resembling the leaves of a book, and hence called "book-lungs." The eyes are simple, never compound, two being situated in the middle of the head, others on each side of it. There may be as many as five pairs of nephridia. The genital outlet is single instead of being double, as in *Limulus*. They have a pair of malpighian tubes or urinary vessels, but, like *Limulus*, possess two large digestive glands, the "liver."

The young are hatched in the form of the adult, there being no metamorphosis except a slight one in the mites. Their embryos have, on at least six abdominal segments, rudiments of limbs, which indicate their descent from animals like *Limulus*. All of the *Arachnida* are terrestrial, none of them living in or near fresh-water, except a few mites. Their embryology is like that of *Limulus*, which suggests that the *Arachnida* have descended from the *Merostomata* (q.v.). Whether we take into account the mode of development or the very primitive nature of the appendages, it appears that the *Arachnida* are much less closely allied to insects than was formerly supposed. On the other hand, they differ from the merostomes, and especially their living representative, the king crab (q.v.), in having no gills. Their embryology and morphology tend to show that the class has probably descended from limuloid ancestors, of which there are examples in the Silurian rocks, intermediate between limuloid (*Xiphosura*) and eurypteroid (*Eurypterida*) forms. The characters in which *Arachnida* resemble insects, as respiration by tracheæ and the presence of urinary tubes (which do not occur in *Crustacea* or in any other marine or branchiate arthropods), are probably adaptive and were acquired during a change from a marine to a terrestrial life, and not primitive heirlooms. *Arachnida* also show their later origin than merostomes by the fact that their sexual ducts (oviduct, etc.) are in most cases single, unpaired, and in all cases open externally by a common single genital aperture in the median line of the body, at the base of the abdomen. In this respect *Limulus*, with its pair of genital (male and female) openings, situated each at the end of a papilla, which are placed widely apart at the base of the first abdominal legs, is decidedly more archaic. The *Arachnida* are divided into six groups or orders: (1) *Scorpionida* (scorpions); (2) *Pseudoscorpionida* (false- or book-scorpions); (3) *Pedipalpida* (*Phrynus* or scorpion-spiders); (4) *Solpugida* (galeodes); (5) *Phalangida* (harvest men); (6) *Araneida* (spiders); (7) *Acarida* (mites and ticks), the latter comprising the aberrant and degenerate forms, many of them parasitic; while of somewhat doubtful relationship to the *Acarina* are three aberrant groups: the *Linguatulida, Pycnogonida,* and *Tardigrada*. See MITE; SCORPION; SPIDERS.

Several of the *Arachnida* are of interest in medicine. A few of the scorpions are poisonous, their sting even causing death, although it is quite certain that there are no poisonous spiders north of Mexico. A number of the mites are found in man. One, the *Demodex canis*, is frequently found in the sebaceous follicles of the skin, notably in comedos, or blackheads. The itch mite (*Sarcoptes scabeii*) bores little canals under the skin, in which it deposits its eggs. The itch is a common disease of Europe, and is becoming more frequent in this country. Sulphur ointment is one of the best parasiticides for this small nuisance.

In the warm countries ticks (*Ixodes*) are troublesome pests. See PARASITES.

Arago, ä'rą-gō, **Dominique François**, a celebrated French astronomer: b. in Estagel, 1786; d. in Paris 2 Oct. 1853. After studying at the Polytechnic School at Paris he was appointed secretary of the Bureau des Longitudes, and in 1806 was associated with Biot and in completing the measurements of Delambre and Mechain to obtain an arc of the meridian which was to serve as the basis of a new metrical system. In 1809 he was elected to fill the seat left vacant by the death of Lalande in the Academy of Sciences, and at the same time he was appointed a professor of the Polytechnic School. In 1811 he communicated to the Institute a paper on a particular modification which the luminous rays experience in their passage through certain transparent bodies, thus paving the way for some of the most brilliant discoveries made in optical science since the days of Newton. In 1812 he began a series of lectures on astronomy, which created an immense sensation. With Gay-Lussac he established in 1816 the ‹Annales de Chimie et de Physique.› His discovery of the magnetic properties of substances devoid of iron procured him the Copley medal of the Royal Society of London in 1825, and a further consideration of the same subject led to the equally remarkable discovery of the production of magnetism by electricity. In 1830, on the death of Fourier, Arago succeeded him as perpetual secretary to the Academy of Sciences, becoming in the same year director of the Observatory. After the expulsion of the Bourbons Arago was elected to the Chamber of Deputies as representative of the Pyrénées-Orientales, taking his place on the extreme left, and proving a ready and effective speaker. The revolution of 1848 brought him still more prominently upon the scene, first as minister of war and marine in the provisional government, and then as a member of the Executive Committee of the National Assembly. His ‹Works,› edited by Barral, appeared in 1854–62.

A'ragonite, a mineral having the formula $CaCO_3$, and therefore identical with calcite in composition. It is classed as a separate species, however, because it crystallizes in the orthorhombic system. Its specific gravity is also somewhat higher than that of calcite. Occasionally it contains a little strontium, lead, or zinc, and it often occurs in connection with pyrites, galena, or malachite. It is translucent and usually white with a vitreous lustre. In hardness it varies from 3.5 to 4, and it has a specific gravity of about 2.94. Aragonite occurs in fine crystals at Aragon, Spain (whence its name), near Bilin, Bohemia, in Hungary, and Sicily, and near Frizington, England. There are no important American localities, though it occurs on stalactitic calcite in caves in New Mexico, Arizona, and elsewhere. The coralloidal form, called «flos-ferri,» is most beautifully developed in Styria. It is said to be forming rapidly at the present time in the Eureka mine in Nevada.

The minerals aragonite, bromlite, witherite, strontianite, and cerussite, all of which are carbonates crystallizing in the orthorhombic system, are classed together as the «aragonite group.»

Ara'lia, the designation of a widely distributed genus of about 400 species of dicotyledonous shrubs, trees, and perennial herbs typical of the natural order *Araliaceæ*. The species have large alternate deciduous leaves, small umbels of whitish flowers usually arranged in panicles, and 2- to 5-seeded, variously colored, globular, berry-like drupes. All parts of the plants have a warm, aromatic taste. *A. spinosa*, devil's walking-stick, angelica tree, Hercules' club, toothache tree, a very ornamental shrub or small tree about 12 feet tall (sometimes 40 feet), is common in moist woods and along river banks from Pennsylvania to Indiana and southward to the Gulf of Mexico. Its very stout, prickly stems, large pinnate leaves, and clusters of flowers which appear in midsummer, give a decided sub-tropical effect upon lawns in the South. It is not hardy in the North. *A. racemosa*, spikenard, a widely branched herbaceous species, with large, spicy, aromatic roots and greenish-white flowers which appear in midsummer, is common in rich woods from New Brunswick to Minnesota and southward to the mountains of Georgia. *A. nudicaulis*, wild sarsaparilla, small spikenard, a nearly stemless herbaceous species with a single pinnate leaf a foot high, is common in rocky and sandy places from Newfoundland to Dakota and southward to the mountains of North Carolina. It bears from two to seven umbels of greenish flowers in late spring. The long, horizontal, aromatic roots are believed to be equal to those of sarsaparilla as an alterative and tonic. *A. hispida*, wild elder, bristly sarsaparilla, a bristly stemmed perennial found in the same localities and soils as the preceding. It bears several terminal umbels of white flowers in early summer. Among foreign aralias the Asiatic species are perhaps of most importance. Some, notably *A. edulis* (*A. cordata* of some botanists), are of value as human food; others as stock food when grasses are scarce. The pith of *A. papyrifera* (referred by some botanists to *Fatsia papyrifera*) is used for the manufacture of Chinese rice paper. *A. chinensis*, Chinese angelica tree, is much like its American relative, *A. spinosa* (to which it is referred by some botanists), but is hardier and blossoms somewhat later. *A. polaris* (*Stibocarpa polaris* of some authors), a New Zealand herbaceous perennial, is four or more feet tall and has attractive foliage and handsome waxy flowers. Many other species are cultivated either out of doors or in greenhouses for ornamental purposes, for which uses their symmetry and grace specially fit them. Among the best known of these are *A. elegantissima*, a native of New Hebrides, and *A. veitchii*, indigenous to New Caledonia. The stronger growing species are propagated by cuttings of roots or stems; the more delicate by grafting on the strong species. For *A. quinquefolia*, better known in America as *Panax quinquefolia*, see Ginseng.

Aransas (ą-răn'zăs) **Bay**, an inlet on the coast of Texas, connected with the Gulf of Mexico by a channel known as Aransas Pass. A bar at its mouth renders its harbor of very little commercial importance, in spite of the money lavished in various attempts to establish there a harbor and port of entry. During the Civil War it was the scene of a conflict between the Confederate and Federal troops.

Ar'arat, or **Pilot Mountain**, an American mountain about 3,000 feet in height, in Surrey County, N. C. It is situated between the Ararat and Dan rivers and is visible for a long distance.

Aras, a-räs, a river of Armenia, rising in the Turkish pashalic of Erzerum. After flowing for some miles through Turkish territory to the new Russian frontier, it turns eastward to the Ervian plain north of Ararat, whence it sweeps in a semicircle mostly between the Russian and Persian territories to its confluence with the Kur, 60 miles from its mouth in the Caspian Sea. Its entire course is about 500 miles. Modern research has discovered that it originally flowed directly into the Caspian Sea, as ancient writers had claimed. It is identical with the ancient Araxes.

Arauca'nians, ä'row-kä'ne-ans, a South American native race in the southern part of Chile, formerly occupying Chile, Argentina, Chiloe, and the Chonos Archipelago, etc. When first encountered by the Spaniards in 1535 they were a confederacy of the loosest kind, with many tribes and sub-tribes in entire independence, and in about the same political stage as the North American Indians: electing a *toqui* or war-chief and deposing him at will, with no authoritative head in peace, practising polygamy, and for worship conciliating an evil spirit, Quecubu,— probably the same as the Fuegian spirit immortalized by Shakespeare as "Setebos," the shape given it by Magellan's sailors. They were divided into Picun-che or Northmen, living north of the river Maule; Pehuenche or Pine-men, occupying through central Chile and the pine forests on the western slopes of the Andes (the chief division of the tribe, and from whom most of the modern Araucanians are descended); Huilli-che or South-men, occupying the rest of the Chilean mainland; Puelche or East-men; South-men or Patagonians; Chono; Lubu-che or Water-men; Cuncho; Payo, etc. But their instant and indomitable cohesion in face of the Spanish attack shows that they were of much higher political stamp than the North Americans. No other native race in the western hemisphere retained its independence anything like as long. For over two centuries they waged warfare with the Spaniards, broken only by truces sought by the latter, though their numbers were small compared with the Aztecs or Quichuas, who went down at a blow. Ercilla's famous epic 'Araucana' commemorates their early heroism and that of their powerful chief, Caupolican. In 1641 Spain conceded their independence, confirming it in 1655, imposing only the condition that no enemies of Spain should be allowed to enter their country; an easy condition, as it amounted only to keeping out all foreigners, which they were glad to do. The territory left them was about 30,000 square miles, from the Andes to the sea, and from Arauco Bay to the river Calle-Calle. The war was renewed nevertheless, and went on a century and a third longer; till in 1773 the natives, weakened by war and social practices, were compelled to submit. They had not lost the memory of their past, however, and in 1861 a French adventurer named Antoine Tounens, originally a provincial lawyer, had himself elected king of Araucania as Orélie Antoine I.; but the Chilean government conquered and deposed him and sent him back to France. In 1870 the Araucanians recognized the sovereignty of Chile. Araucania occupies a great part of the province of Arauco in south Chile, and is divided into four parallel north-and-south districts, each formerly governed by a *toqui* whose rule had become hereditary before its extinction. The inhabitants are now a mixed race with much Spanish blood. They number perhaps about 50,000, but are said to be decreasing, owing to smallpox, dysentery, liquors, and polygamy. They are of a pale yellow color, and in character and life resemble the higher North American plains Indians, such as the Navajos. They are uncivilizable and unchristianized; nomad herdsmen of horses, cattle, and sheep; despising agriculture, eating little but meat, and living in skin tents; but skilful wool-weavers, skin-dressers, and weapon-makers. Their language is so harmonious and flexible that an enthusiastic missionary student once attempted to introduce it into Europe to supersede Latin. Their stock in Chiloe are called Chilotes.

Ar'auca'ria, the name of a genus of 15 species of lofty evergreen trees of the order *Coniferæ*, indigenous to Australia and South America. In general habit the species resemble the pines, but have broader leaves. In warm but not excessively dry climates they are much planted for ornament, but in cool countries are grown in greenhouses on account of their tenderness. They are propagated by seeds and cuttings planted in good soil and grown in a cool greenhouse. *A. excelsa*, Norfolk Island pine and its varieties, *glauca* and *robusta compacta*, unquestionably the most popular species grown in the United States, is imported to the extent of probably 250,000 annually, from Belgium, where it is grown in immense quantities. In Norfolk Island, its home, it often attains a height of 200 feet (100 feet to the first branches) and a diameter of 10 feet near the base. The white, close-grained tough wood is so heavy that it barely floats in water. *A. cunninghamii*, hoop pine, Moreton Bay pine, colonial pine, coonam, cumburtu, coonong, a native of New South Wales, is similar to the preceding, but somewhat smaller, of less formal and symmetrical habit. Its lower branches are horizontal, its upper ascending; one of its varieties, however, is weeping. Its yellowish wood is highly valued for carpentry, shipbuilding, and furniture-making. It also furnishes a valuable resin. *A. imbricata*, Chile pine, monkey puzzle, a native of the western slopes of the Chilean Andes, attains a height of 150 feet, and is limbless except near the top. It furnishes an abundant supply of valuable white resin which smells like frankincense. Its timber, which is used for ships' masts, is yellowish white, handsomely veined, heavy, and hard. Its huge cones, often eight inches in diameter, frequently contain several hundred seeds, which are largely used as food, either raw, roasted, or boiled, by the Chileans, who also distil a liquor from them. *A. braziliana*, Brazilian pine, a native of southern Brazil, is a more spreading species than the above, which seldom greatly exceeds 100 feet in height. Its seeds are also used as food; its resin for mixing with wax in candle-making. *A. Bidwellii*, bunga-bunga, of Australia, attains a height of 150 feet and a diameter of four feet. It furnishes a less valuable timber than *A. cunninghamii*, an important resin, and every three years a crop of large seeds used by the natives as food. It rivals *A. excelsa* in beauty as

a pot plant. *A. cookii*, named after Capt. Cook, the explorer, reaches a height of 200 feet, and *A. pulei*, both natives of New Caledonia, are useful for ornamental purposes and for their products of timber, resin, etc. In California and the southern States these trees have been found to succeed well as out-door specimens.

For cultivation consult Bailey, 'Cyclopædia of American Horticulture'; Nicholson, 'Dictionary of Gardening'; Von Mueller, 'Select Extra-Tropical Plants Readily Eligible for Industrial Culture.'

Arauco, a-row'kō, the name of a province of Chile with an area of 4,248 square miles. It is but a strip of coast at present, but was formerly much more extensive. Capital, Lebu. Pop. (1901) 75,000.

Araujo de Azevedo, a-row'zhō dā ä-za-vā'do, a noted Portuguese statesman: b. in Sa, 1754; d. in Rio Janeiro, 1817. He became minister of foreign affairs in 1803, but on the capture of Lisbon by Napoleon in 1807 accompanied the king to Brazil. At Rio Janeiro he founded schools of fine arts and medicine, introduced the tea culture into Brazil and was an active patron of agriculture and other industries. In 1815 he was created Count of Barca. His literary pretensions were not inconsiderable.

Araujo Porto-Alegre, a-row'zhō pôr'tō-a-lā'grā, **Manoel de,** a Brazilian poet and architect: b. Rio Pardo, 1806; d. 1879. He not only designed several important buildings in Rio Janeiro, but was the author of several comedies, of 'Colombo,' an epic, and 'Brasilianas,' a collection of poems (1863).

Arauna, ä'ra-oo'na, the name of a South American tribe whose home is on the borders of Peru and Bolivia, regarding whose appearance and customs travelers differ widely. According to some accounts they are naked and ill-formed cannibals, while according to others they are light-colored, mild-mannered agriculturists.

Araure, a-row'rā, a town in Venezuela in the State of Lara, the centre of a fertile region producing coffee, cotton, and cattle. The battle of Arame took place near here, 4 Dec. 1813. Pop. 4,000.

Aravulli, ăr'a-vul'le, or **Aravalli,** a mountain range in Hindustan about 300 miles in length. Its river system is extensive, but the valleys enclosed within the range are mainly sterile.
